—i.e., were to require a real knowledge of medicine, not the acquisition by rote of endless minutiæ of no value whatever to anyone." Launched into practice in a small governmental town of Middle Russia, VERESAEFF finds that his troubles only now really begin. He has never held a resident appointment in a hospital and has consequently had no real experience in the treatment of disease or in the management of patients. The effect of his doubts, his anxieties, and his mistakes upon a man who had enough intelligence to realise them and more than enough conscientiousness to suffer from them is such that he relinquishes practice in order to gain further real experience in hospital work. His reflections are bitter enough upon a system which has labeled him legally fit to practise without necessitating his being in any way actually efficient. "Who would think of sending out to battle soldiers who had only seen others shoot? Yet *doctors enter upon life clumsy recruits unable to handle their arms.*"

VERESAEFF'S next mental tortures—it will be realised that his early experiences in medicine afforded him anything but peace of mind—arose from the contrary results of therapeutic experiment. Drugs extolled on one side he finds deplored upon another and the treatment of one eminent authority is pronounced disastrous in the hands of another equally distinguished. At last, however, after painful years of unpaid hospital work and laborious private practice he finds his feet. "It was true that science gave me less than I had anticipated and that I was no genius. But would I be in the right to renounce my diploma? Were we average doctors so utterly useless? ...... We can be useful and accomplish much, on condition of rigid adherence to the old maxim *primum non nocere.* And, in the next place, we must once and for all discard the notion that our work consists in careless and unquestioning obedience to the mandates of science. We must realise how complex and responsible is the work before us, work unceasingly at self-improvement, and never rest or pause in our quest for truth. All this is terribly hard and many may faint beneath the burden; but as long as I find strength to bear it honestly I have the right to remain at my post." We should like to deal with those passages in which the author shows how little the medical man's difficulties are comprehended and sympathised with by the average person and to relate the cases which he quotes of unfair charges and newspaper comments upon medical men. Space, however, forbids us to go further than to recommend this book as one which, if it contains a great deal which cannot be read with advantage by the ordinary reader, is at any rate a work of the highest interest to the medical man and likely to stimulate in him only the most laudable ambitions and reflections.

◆

The Oliver-Sharpey Lectures.

IT is always pleasing to connect with recent researches the name of one who has contributed to them by the stimulating influence of his teaching. In the Oliver Sharpey lectures lately delivered at the Royal College of Physicians of London[1] Dr. GEORGE OLIVER, before approaching his subject, paid graceful tribute to his indebtedness to the lucidity and impressive character of the work of WILLIAM SHARPEY and reminded us that the aim of the endowment of these lectures was to foster the application of physiological knowledge to the prevention, alleviation, and cure of disease and the prolongation of life. The intimate connexion between physiology and medicine has long been recognised but those who labour in the interesting field of research must always be grateful to the clinician who is able and willing to extend the researches into the domain of practical medicine and to indicate their bearing upon alterations occurring in disease. It must be admitted that in these lectures Dr. OLIVER has set an example which is worthy of all commendation. Selecting as his subject Recent Studies on the Tissue-Lymph Circulation he has presented in the first lecture the results of recent work by himself and by others concerning the physiological conditions of the tissue-lymph circulation, while in the second he has given numerous valuable indications of the deductions which may be drawn and of the influence these researches will probably have upon the medicine of the future. It will be seen that he considers they throw a new light upon the explanation of gouty conditions and towards the end of this lecture he has suggested several new methods of treatment which will, no doubt, soon be submitted to rigorous investigation by those who have abundant opportunities of verifying or disproving the claims made on their behalf.

To some extent the first lecture is an extension of the author's Croonian lectures delivered in 1896. After dealing with the effect of the ingestion of food on the tissue-lymph circulation he considers in detail the alterations in the blood during digestion, noting changes in the corpuscles, in the hæmoglobin, and in the specific gravity. His observations on the variations of muscular contractility after food show that they always follow a certain order, from which he is able to draw valuable conclusions in relation to the effects of exercise and sleep. When dealing with the influence of sodium and potassium chlorides upon the arterial pressure and the outflow of tissue lymph reference is made in passing to the important rôle assigned by the late Sir WILLIAM ROBERTS to sodium chloride in the pathogeny of gout and to his valuable suggestion that gouty subjects might derive benefit from the substitution of potassium chloride for sodium chloride. Dr. OLIVER, pursuing a totally different line of inquiry, reaches the same conclusion —that sodium chloride favours, while potassium chloride inhibits, a gouty tendency. The section dealing with the influence of muscle extractives upon tissue-lymph circulation and upon the blood pressure is that which demands the most careful study, since this affords the key to the treatment which is formulated in the second lecture. This section really forms the major premiss of the syllogism and accordingly its verification is of the utmost importance. The conclusions merit quotation: "Such bodies as uric acid, creatin, creatinin, xanthin, glycogen, and sodium chloride perform an important function in nutrition, for during digestion they act as distributers of lymph to all the tissues, an office which the nutrient constituents themselves (proteids, fats, and carbohydrates) are incapable of discharging."

In the second lecture Dr. OLIVER deals with the influence of exercise, fatigue, rest, sleep, respiration of gases, internal secretion, temperature, and gravitation before reaching the consideration of the practical deductions and the new remedies suggested by this inquiry. It is interesting to note that he believes that the removal of lymph from the tissues is largely the result of absorption rather than of transmission along the lymphatics and the view of the relative part played by the short circuit by absorption and the longer circuit by the lymphatics is supported by details of a simple experiment which may easily be performed. The explanation of the efficacy of massage in relieving the sense of fatigue and the happy reference to the treatment of the weary heroes of the Odyssey, with the pithy remark that "human instinct, without knowing 'why,' practised what is now taught by physiological inquiry," will serve to show the readiness with which Dr. OLIVER annexes from ancient practice and modern teaching facts in support of his contention. Similar readiness is displayed with regard to the changes which occur during sleep. Consideration of the influence of the respiration of various gases upon the blood pressure and lymph circulation naturally leads to brief reference to the effect of sulphuretted hydrogen, notably in connexion with Harrogate water and an explanation of the recognised value of the compound sulphur lozenge introduced by Sir ALFRED GARROD. Extremely curious, and we believe quite new, is the observation, with its explanation, of the tendency of those working in sewers to become "rheumatic or quasi-gouty" in comparatively early life. Although Dr. OLIVER refers this tendency to an unknown emanation in the sewer atmosphere acting as a lymph factor it would be interesting to know by what means, apart from the observations he describes, he has eliminated the possible influence of other factors, such as alcohol or an excess of meat. In spite of the value of the researches connected with internal secretion practitioners will find the most absorbing interest in the practical deductions, and here it is important to bear in mind the distinction that is drawn between the arterial pressure and the "working physiological blood pressure" of the capillaries. The relative work is admirably expressed in very few words: "The arteries and veins are but conduits for the passage of blood to and from the seat of the metabolic traffic—the capillaries." From this point most of the lecture is concerned with gout in its protean forms, "a term which has been regarded by some as a convenient label for a sort of rubbish heap of nondescript ailments." The adoption of the views here enunciated would serve to produce some order out of chaos and certainly Dr. OLIVER supports his argument by practical suggestions for a dietary which is admitted to be beneficial and for which he supplies a rational explanation. The remedies enumerated include Witte's peptone, ammonium hippurate, lichenin, glycogen, and lævulose, and they are introduced as the outcome of the author's experiments, their claim to consideration being mainly based upon physiological observations. Dr. OLIVER, so far from speaking of them in glowing terms which might inspire distrust, admits that though he has employed them only in a tentative way the results encourage him to prescribe them. Introduced with such modest reservation but with an apparently sound physiological reason, these remedies seem to merit extended trial. The provisional conclusions with which the second lecture closes deserve thoughtful consideration. It is of the utmost practical importance to gain a "clearer insight how to control disarrangements of nutrition and metabolism," but many further experiments by other workers are needed before it can be admitted that Dr. OLIVER is right in thinking that this can be attained solely or mainly "by studying the conditions which increase or decrease lymph effusion." Meanwhile he is to be congratulated on the interest which his lectures must evoke and upon the skill with which he has demonstrated the intimate connexion between physiology and medicine.

Annotations.

"Ne quid nimis."

THE AMENDMENT OF THE LUNACY ACTS.

Sir John Batty Tuke availed himself of the vote for the maintenance of the Lunacy Commission for England and Wales in order to lay before the House of Commons the extreme inadequacy of this Commission as at present constituted and to ask for some inquiry into the subject. He pointed out that there are only three medical commissioners to supervise the treatment of 114,000 lunatics, so that, while in Scotland there is one such commissioner to every 3622, in England the proportion is one to 38,000, and he maintained that a Commission so undermanned must necessarily work in a wooden fashion, unsympathetically and without elasticity. The numerical inadequacy of which he complained was, he said, growing worse and worse, for there had been no enlargement of the Commission since its establishment in 1845, while the number of the insane had increased nearly five-fold and while a great change had come over the conception of insanity. The insane person was no longer regarded as a pyschological curiosity but as a pathological subject. The nation was doing its best to stamp out tuberculosis and cancer but it was not doing its best in respect to a disease which attacked three persons out of every 1000 and which, if not arrested, consigned its victims to a living death. Sir John Tuke was well supported by other medical Members of the House, and especially by Sir Michael Foster, who declared that in no branch of science had there been greater progress during the last generation than in the knowledge of the brain and the central nervous system. That wonderful web of delicate fibre and cells was being gradually unravelled and day by day a command was being obtained over the brain which was unknown when the Lunacy Acts were introduced. Though medical science had reduced other diseases, lunacy, if anything, was on the increase, and the main fault was in the present state of the lunacy laws which, if they did not hinder, certainly did not facilitate the application of science to the disease, especially in its early stages, in which it was most likely to be amenable to treatment. He proceeded to show the necessity for changes in the present methods of notification and certification and strongly supported Sir John Tuke's demand for a complete inquiry. Dr. R. Farquharson, who followed, dwelt upon the superiority of the Scotch method of managing what are often described as "border cases" and declared that there ought to be special hospitals or special wards and special pathological institutions. In fact, there was a general recognition by the medical Members of the House that the time had come when insanity should be regarded as a disease like other diseases and that it should be investigated and treated by ordinary clinical methods.

The Attorney-General, in rising to maintain on the part of the Government that everything is for the best in this best of all possible worlds, "was not satisfied" that there was any proof of increase of insanity. He has, however, presented a Bill, which was read for the first time on Wednesday afternoon, having for its object the amendment of the Lunacy Acts. His somewhat unscientific attitude in his speech makes of his practical action a pleasant surprise.

INFANTILE MORTALITY.

IN his report on the infantile mortality in the borough of Croydon, a report which covers a period of several years up to the end of *1903, Dr. H. M. Richards*, the medical officer of health, has amassed a large amount of information which is likely to prove of considerable service to the borough council in arriving at a satisfactory method of abating the unnecessarily high rate of mortality among infants in its district. The borough of Croydon is a very large one and covers nearly 10,000 acres of ground. It has an annual birth-rate which approaches 4000 and the annual number of deaths which occur among infants under one year of age very nearly reaches 400. To be exact the infantile mortality for the year 1903 was 133 per 1000 children born. This figure, though unnecessarily high, compares favourably with the mortality of many other districts. It has been Dr. Richards's object to investigate so far as possible the causes of this high mortality and to suggest such remedies as may prove of real practical value, not only for his own district but for others similarly situated. His investigations have, among other results, led Dr. Richards to the conclusion that perhaps the most essential element in the prevention of deaths among infants is the exercise of intelligent supervision on the part of the mothers. The greater the degree of poverty the greater the need for intelligence to compensate for the concomitant disabilities associated with defective food-supply and bad hygienic conditions. The education of the mother and of the rising generation of girls in the elements of nursery hygiene and in the principles of infant feeding must constitute, therefore, one of the most important factors in any scheme which has as its objective the reduction of infantile mortality. The preponderating proportion of deaths which occur among artificially fed infants clearly indicates the need for the encouragement of the natural method of feeding. Municipal cleanliness, especially in respect of the efficient scavenging and watering of the streets, is insisted upon by Dr. Richards as an important element in the maintenance of domestic cleanliness and as a corollary in the prevention of diarrhœal and other infectious diseases. Experiments carried out by the Croydon sanitary committee on the lines of more thorough scavenging and watering of a particular section of the East Ward were followed by improvement in the mortality among infants which was, to say the least, suggestive that such hygienic precautions were important elements in the prophylaxis of diarrhœal and other infantile complaints. To meet the difficulty in regard to substitute feeding in those cases in which breast feeding is unobtainable Dr. Richards considers the advantages of a municipal milk depôt for the purpose of providing at a reduced cost for the poor a supply of properly modified milk. We gather that the medical officer of Croydon, although by no means enthusiastic with regard to such a scheme, is on the whole in favour of the establishment of a depôt for his borough, although he admits that owing to the very large area it would have to serve many difficulties and complications will necessarily arise which may not have been in operation in other districts where this method has been successfully carried out. Be the advantages, however, of a milk depôt what they may, we cannot too strongly endorse Dr. Richards's view that even when a mother has been provided with the proper food for her infant only a short way has been gone towards rearing a healthy child. By far the most important results may be expected from educational methods and by the insistence of domestic cleanliness. No doubt a very great deal could be done by systematic visits from health visitors, by addresses and lectures, and by practical instruction to the elder girls in elementary schools, but there still remains the difficulty, at least so far as London is concerned, that domestic cleanliness is to some extent a question of expense.

MEDICAL DEFENCE.

THE scheme of medical defence as prepared by the Medical Defence Committee of the British Medical Association was submitted to criticism at a recent meeting of the South-West (Wandsworth) division, an account of which will found at p. 1452 of our present issue; and the result cannot be regarded as wholly satisfactory. Very properly the discussion was at first limited to the advisability of medical defence being undertaken by the British Medical Association, any reference to a scheme being ruled out of order until an expression of opinion had been given on the broad question. It was evident at a very early stage that the position of the Medical Defence Union formed the chief obstacle. While it was suggested that the new development of the British Medical Association would benefit by the experience and coöperation of the Medical Defence Union and of the London and Counties Medical Protection Society it was clear that the former body possessed strong views against the expediency of any such amalgamation. These views were ably stated by Dr. A G. Batemen and have already been discussed in these columns.[1] At the meeting at Wandsworth the matter was regarded mainly as influencing members of the medical profession who were already members of the Association and by 16 votes against seven it was ultimately decided that the meeting considered it desirable that the British Medical Association should take up the question of medical defence. Before the air was thus cleared it was stated on behalf of the Medical Defence Union that there was no intention of "winding up" and there really seems no valid reason why it should not continue its good work for the general practitioner who objects to being obliged to join the ranks of the British Medical Association before he can receive the benefits of protection by further payment. This side was more fully discussed when the scheme was before the meeting, but progress was blocked by an impossible motion to the effect "that no scheme submitted by the Association could carry on medical defence safely and efficiently until it has been prepared by a committee including the medical defence societies in their official capacity and after duly consulting its members through the divisions." Sir Victor Horsley ably urged the adoption of the scheme and while indicating that the existing societies should be invited to merge themselves in the Association he admitted that if the societies were not willing to come in he considered it a very open question whether a third body should be instituted. Much of the discussion of the scheme was far from helpful. Objection was raised to the submission of a scheme "to pass, to tinker up, or to decline." What could it matter where it originated so long as the meeting was asked to approve, to amend, or to reject it? From Dr. Bateman's inquiries members of the Association who are members of the Medical Defence Union are not in favour of amalgamation and it is therefore to be presumed that this body will continue, even should the British Medical Association succeed in gaining over the London and Counties Medical Protection Society. The moral support of the strong financial position of the British Medical Association was freely urged as an advantage of the scheme and this must necessarily become an inducement to attract into the fold those who are not already attached to the British Medical Association. After very prolonged discussion upon many subjects, from medical defence to the funds and expenditure of the Association and to its influence on medical men "in the antipodes, in India, in Canada, all over the world, all over the empire," the motion was put to the meeting and lost, and then it was agreed to adopt the principle of the scheme and to refer it to the committee of the division. When it is remembered that this lukewarm approval of the scheme was all that could be gained by Sir Victor Horsley's spirited advocacy it seems probable that the idea of medical defence being undertaken by the British Medical Association is not likely to be accepted so long as the Medical Defence Union holds aloof.

TRANSVERSE WHITE LINES ON THE NAILS DUE TO ARSENICAL POISONING.

THAT transverse white lines on the nails are a sign of a passed illness is an old observation, but it was only after the epidemic of arsenical poisoning in Manchester and the north of England due to drinking contaminated beer that this condition was found to be one of the results of arsenical poisoning. *A priori* the marked action of arsenic on the epidermis would lead an observer to expect some effect on the nails which are only modified epidermis. Dr. E. S. Reynolds, to whom the merit is due of first pointing out this effect as well as of discovering the cause of the epidemic, found in some cases "a transverse white ridge across the nails; proximal to this the nail is normal but distal to it the nail is whiter, cracked, thin, and towards the tip almost papery and much flattened. In some cases there has been a series of parallel transverse ridges almost suggesting a series of week-end drinking bouts."[1] In the *American Journal of the Medical Sciences* for April Dr. C. J. Aldrich has described under the title of "Leuconychia Striata Arsenicalis Transversus" three cases of white lines on the nails due to arsenical poisoning. In one case a woman was suffering from severe arsenical neuritis, the result of taking with suicidal intent a teaspoonful of a rat poison. On the nails were white crescentic streaks about one sixteenth of an inch wide and presenting a curve identical with that of the lunula. On the toe-nails the streaks were less distinct. The body was covered with branny desquamation, much of the hair had fallen, and the palms and the soles showed some keratosis. From the position of the lines on the nails the time when the arsenic was taken could be estimated. In the second case a man sought advice for neuritis. He gave a history of "stomach difficulty" with hæmatemesis three months previously. Soon his legs became weak and he could get about only with the help of two sticks. He was ataxic and had foot-drop, the knee-jerks were absent, and there was some loss of sensibility On the nails were transverse lines similar to those described above. The patient on being told that his symptoms probably were due to poisoning at first demurred but then admitted that he had been poisoned with arsenic, refusing to give any explanation. In the third case a man, aged 29 years, addicted to alcohol and tobacco gave a history of abdominal pain, severe vomiting, and cramps in the arms and the legs three months before he came under observation. Six weeks later he began to lose power in the limbs and the arms became numb. He walked with sticks and had an ataxic gait. The knee-jerks were absent and the lower limbs and the fingers were slightly anæsthetic. On the nails were crescentic white streaks which so much resembled those in the previous case that Dr. Aldrich diagnosed arsenical poisoning. Some time later the patient confessed to having taken an arsenical rat poison. The lines corresponded in position to the time when the arsenic was taken. The toe-nails showed faint markings but there was no keratosis of the palms or the soles. It is to be noted that in Dr. Aldrich's cases there was not a "ridge" on the nails as described by Dr. Reynolds but only a streak. Perhaps the cause of difference was the more chronic poisoning in the latter's cases. These white lines are thus not a mere scientific curiosity but a sign which may prove of great use in the diagnosis of arsenical poisoning—a condition often liable to give rise to difficulties. It may be remembered that arsenical herpes, discovered by Mr. J. Hutchinson many years ago, remained long only a clinical curiosity the very existence of which was doubted by many authorities. But it was the presence of herpes in several cases in the epidemic referred to that gave Dr. Reynolds the clue to the cause.

SMITH *v.* PARE.

THE action of Smith *v.* Pare, recently tried before Mr. Justice Lawrance and a special jury, has ended disastrously for the plaintiff. In THE LANCET of March 14th, 1903, *p. 745, comment was made upon a newspaper article,* a circular letter, and a leaflet which advocated and advertised an alleged new treatment for the cure of cancer by means of high-frequency electricity. The leaflet and the letter associated the "cure" directly with Mr. E. A. Cloete Smith. Our annotation on the subject dealt with the fallacious hopes which such publications were likely to encourage in cancer patients rather than with the propriety of the manner in which publicity was given to Mr. Cloete Smith's methods, but the ethical question was subsequently considered by the General Medical Council and we believe that the circulars had by that time been discontinued. Apparently, however, they had had their effect, which in the case of the wife of Mr. Pare, the defendant in the action referred to, was one unfortunate both for the patient and for the plaintiff. The evidence given at the trial confirms our observations with regard to the probable efficacy of the treatment proposed, and the facts made public show how ill judged was the manner in which it was thrust into notice. Mr. Cloete Smith's friends were no doubt over zealous on his behalf and it must now be a matter of regret to him that they were so. Mr. Pare's wife was operated on by Sir Victor Horsley four or five years ago for an internal growth of such a nature that recurrence was not impossible. In September, 1902, she was suffering from pneumonia and blood poisoning and Mr. H. Huxley, who was consulted, recommended open air treatment, in consequence of which she was subsequently sent to St. Leonards. She was there in February and April, during which period Mr. Huxley did not attend her, but in March the husband showed to him a document which referred to the treatment administered by Mr. Cloete Smith and informed him that Mrs. Pare's relatives were extremely anxious for a trial to be made of it. The same circular was shown to Sir Victor Horsley and there appears to be no room for doubt as to the nature of the opinions which Mr. Pare received. It was that high-frequency electricity would not be likely to do his wife harm but could do her no good. No mention was made of the use of the x rays and there was no consultation with Mr. Cloete Smith whom Mr. Huxley, forming an unfavourable opinion of the ethical aspect of the circular, refused point-blank to meet. Mr. Pare eventually decided to avail himself of the services of Mr. Cloete Smith and the patient underwent the treatment prescribed by him at St Leonards. This, according to Mr. Cloete Smith himself, included at first the application of the high-frequency current twice a day for two hours and the application of the x rays at a distance of from 16 to 20 inches from the body. It was subsequently varied by the discontinuance of the high-frequency electricity but the x rays were applied for some time afterwards, the application of the rays being in the hands of a gentleman with electrical experience but who was not a medical man. A nurse who was in charge of the case, but who had entirely disclaimed all knowledge and refused all responsibility with regard to electrical treatment, deposed that she received no instruction to watch the patient's skin, but that owing to the pain suffered by Mrs. Pare she communicated with Mr. Cloete Smith on the subject. It was in consequence of this that the high-frequency treatment was left off and the nurse upon her own responsibility stopped the application of the x rays after having observed that burning had resulted from their use. Mr. Cloete Smith appears to have ordered their continuance but again the nurse stopped them and informed him that his patient was being tortured. On this occasion he seems to have examined Mrs. Pare and to have said that he had no idea that the burning had been so serious. It was at a date some time later than this that Mr. Pare realised the condition in which his wife was as the result of the use of the x rays, which had caused extensive dermatitis and burning, and the course he took was to seek Mr. Cloete Smith and to assault him, also refusing payment of his fees. The action tried was accordingly brought by Mr. Cloete Smith as plaintiff to recover 100 guineas for professional services and for damages for assault. Mr. Pare denied his liability as to the claim upon the ground that the treatment was useless, counter-claimed for damages for negligent treatment of his wife, and paid £2 into court in respect of the assault which he admitted. The judge after summing up left three questions to the jury, the first of which was as to whether Mr. Pare had consented to the use of the x rays. As to this there had been a conflict of evidence, Mr. Cloete Smith stating that he had mentioned and recommended them in discussing with the defendant the treatment which he proposed to apply, whereas Mr. Pare contradicted this and said that only the high-frequency treatment was mentioned, that he knew nothing of the x rays, and neither consented to them nor was asked to do so. The evidence of the nurse and of other witnesses tended to corroborate Mr. Pare and the jury found that he did not consent to the plaintiff's application of the x rays to his wife. The other questions were whether the treatment was proper treatment to apply, and whether the burning of Mrs. Pare's skin was caused by negligence and want of reasonable skill Upon these points the jury had a considerable body of expert evidence before them as to the condition of Mrs. Pare before and after the treatment, and as to the impossibility of either the high-frequency current or the x rays affecting the internal organs of the body to which they were professed to be directed. With regard to these questions they found that the treatment was improper, negligent, and unskilful. With respect to the assault there was no question for them save as to the damages, for it was not denied that it took place. They assessed the damages at £2, the amount paid into court. With regard to the counter-claim they found a verdict for the defendant for £100. As a consequence of these findings judgment was given for the defendant upon the claim, as the verdict in respect of the assault did not exceed the amount paid into court, and in respect of the counter-claim for £100. A stay of execution was refused. The line of treatment pursued with regard to Mrs. Pare scarcely requires comment. High-frequency electricity may have utility in diminishing pain in cases of malignant disease, but the application of electricity in the manner in which it was applied to Mrs. Pare is not likely to be adopted by medical men generally in respect of patients suffering as she was supposed by her relatives to be suffering when Mr. Cloete Smith's circular attracted their attention. Such ill-advised interference caused her to undergo an extremely painful experience and it is to be hoped that the relatives now feel regret and realise that whenever it is vouchsafed to science to discover any treatment which will stay the progress of a dread disease the discovery is usually the outcome of slow and laborious work, developed gradually by anxious observations and by carefully recorded and compared experiments. Such a discovery, when its utility has been fairly established, is not advertised by pamphlet, circular, or newspaper article as the special monopoly of an individual, but becomes part of a medical science which it is the pride and ambition of a great and learned profession to extend and to promote for the common good of mankind. The practitioner in attendance on the patient, who is acquainted with the patient's needs, can advise as to where skill and knowledge should be sought more correctly than can the gossiping acquaintance or the irresponsible manufacturer of journalistic sensations.

---

[1] THE LANCET, Jan. 19th, 1901, p. 166.

OBSESSIONS AND MORBID IMPULSES.

INSANE obsessions and morbid impulses often play as important a part in human life as do the normal tendencies to thought and action which arise in the healthy and well-developed brain: And occasionally, by a curious irony of nature, it happens that a brain highly gifted in respect of intellectual and artistic endowments is the bearer of a blemish, a neurotic taint, which reveals itself occasionally or periodically in the appearance of absurd and irrational mental obsessions or of dangerous morbid impulses which to the individual are both repugnant and distressing. In the *Journal of Mental Science* for April Dr. James Shaw of Liverpool states that cases of obsession and morbid impulse are much more frequently met with in private than in asylum cases. "They may be physiological, as instanced by cases where catchwords or refrains haunt the mind for hours or days and then vanish" and, like hallucinations, they may be induced by drugs. On the other hand, they may be grave and indicative of some deep-seated, if not serious, taint or maldevelopment of the brain. In a leading article published in THE LANCET three years ago,[1] attention was drawn to the subject of the rhythmic psychoneuroses and morbid impulses which affect many persons on the borderland of mental health. The patient suffering from obsessions, says Dr. Shaw, is quite aware that they are entirely subjective and can describe his symptoms fairly well. He is capable of being reasoned, temporarily at least, out of his morbid fears, recognises any "criminal" tendency of the inciting thoughts, and is able, for a time at all events, to resist their promptings, and is quite alive to the absurdity—and in cases of mania blasphematoria or coprolalia to the obscenity—of his besetting words and thoughts. The besetting words and phrases, which in the sane are probably the equivalent of "voices" in the insane, and the obsessing images are commonly unpleasant and induce thoughts and reactions of distress, surprise, and disgust. Verbal obsessions are those in which words—mostly obscene or blasphemous—constitute the morbid besetment. They differ from coprolalia in that the words are not necessarily uttered by the patient. Such verbal obsessions may constitute the leading feature of a form of "obsessional" melancholia, as in two cases which Dr. Shaw has previously reported in THE LANCET.[2] "Both patients presented marked neuropathic heredity, and extreme religiousness. The words which were described by them as obscene and unutterable, and which were in fact never uttered, caused them intense mental anguish." Both patients had suffered from influenza prior to the mental illness and both presented motor agitation, especially of the arms. A more serious case in which morbid impulses to strike others and to injure himself were present was the following one of a married man, aged 32 years, whose brothers and sisters suffered from hypochondriacal delusions or mental depression. Hitherto he had resisted the morbid impulses referred to, being well aware that these promptings, so foreign to his better nature, were subjective and abnormal. "The inclination to strike sometimes arose without any provocation on seeing a weapon and a person near each other. ...... He was in constant dread of doing something violent. ...... When closely interrogated he said the 'internal voices' or 'loud thoughts' [which impelled him] were in his head." He also had the fixed belief that his soul was lost and he had crude hallucinations of sight and hearing. He saw "flashes of light" before his eyes and heard "creakings and clankings" in corners of rooms. He was full of emotion and would burst into tears when describing his experiences and he was afraid of having to go to an asylum. He was treated with rest, a change of surroundings, tonic cold baths, and medication with bromides and belladonna and aperient tonics. After steady improvement he went away and under the stress of an accident and unfavourable circumstances he relapsed and became worse, so that he had eventually to be placed in an asylum. Emotional, affective, or phobic obsessions may constitute, says Dr. Shaw, almost the whole disease in cases of obsessional aberration (rudimentary paranoia). Perhaps the most typical of these is the fear of open spaces (agoraphobia). An excessive and unreasoning fear of death or of disease makes many persons take extraordinary, though really futile, precautions. Women are especially the subjects of such obsessions of fear of death or of infection. In some cases of morbid impulse the will is occasionally powerless to prevent its execution and the question of responsibility has to be decided. Psychologically, says Dr. Shaw, a species of dissolution appears to take place in the highest cerebral centres (those of control of the thoughts and emotions) in cases of obsession and morbid impulse. Toxic conditions, mental exhaustion, and indulgence in alcohol may cause exacerbation of symptoms by inducing freer liberation of morbid impulses from the brain to the motor centres (impulsive acts). Treatment consists mainly in avoidance of cerebral excitement, rest, massage, hydrotherapy, aperients, cerebral sedatives with tonics, and judicious hypnotic suggestion.

THE UNIVERSITY OF WALES AND A MEDICAL DEGREE.

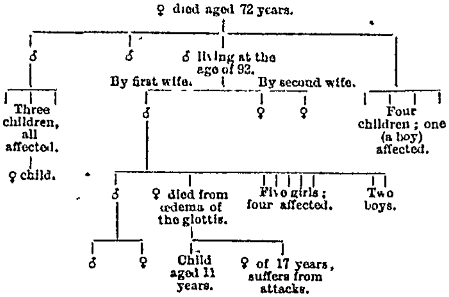
THE annual meeting of the court of the University of Wales was held on May 13th at Holyhead when Sir Isambard Owen, the senior Deputy Chancellor, who presided, referred to the fact that the University is not at present empowered to confer degrees in medicine and surgery although it prepares medical students for the preliminary examinations of other universities. Consequently students from Welsh schools were taking important places in other universities while the University of Wales lost the credit of their training. In order to obviate this Sir Isambard Owen suggested that a petition should be made for a supplemental charter which should enable the University to grant degrees in medicine, surgery, and obstetrics. H.R.H. the Prince of Wales, who is Chancellor of the University, has written through Sir Arthur Bigge signifying his approval of the proposal which was also advocated by Sir John Williams. The court accordingly decided to make application for a supplemental charter. We hope that the University of Wales will be successful in obtaining its request. Nowadays the possession of a medical degree is of great value to members of the medical profession. In the absence of a one-portal system, the institution of which seems now to have receded to an indefinite distance, it is puzzling for the public that some of the best equipped and ablest general practitioners in our body are not in possession of a doctor's degree. We welcome therefore the opportunities that are afforded by our new universities. But it must be pointed out that such a boon to local students as the possibility of obtaining an M.D. degree makes the plight of the London student additionally hard seeing that he can only obtain a doctorate from his university upon terms that are arduous as compared with those exacted by many other universities.

THE LATE MR. ADRIAN HOPE.

THE death of Mr. Adrian C. F. Hope, which took place at St. Thomas's Home on May 10th after an operation for appendicitis, has caused profound regret, especially amongst those members of the medical profession with whom he has been associated at the Hospital for Sick Children, Great Ormond-street, London, W.C., of which he was secretary. Mr. Hope was the eldest son of Colonel W. Hope, V.C., and at one time held an appointment at the Bank of England. He afterwards became private secretary to the Governor of Ceylon and in 1885 he was appointed secretary to the Hospital for Sick Children—a position for which he was eminently suited by reason of his sympathetic, tactful, and courteous nature. The welfare of the little patients for whom Great Ormond-street Hospital was founded was the one great object to which he devoted his life and the important position which that hospital has taken among children's hospitals is due in no small measure to the energy which he threw into his work. To his initiative was due the Coronation bazaar which was held in aid of the hospital in 1902 at the Royal Botanic Gardens and opened in July of that year by Her Majesty the Queen. Apart from the historic character of the bazaar it was remarkable for the brilliancy and distinction of its patrons. The visitors included most of the well known leaders of society, many representatives of our colonies, and several Indian princes. The sum realised on that occasion amounted to £19,000. Though the work of the Hospital for Sick Children occupied almost the whole of his time Mr. Hope found opportunities for helping hospital work in other directions and was president of the Hospital Officers' Association.

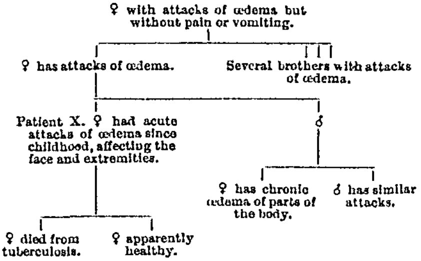
NEUROTIC ŒDEMA OF HEREDITARY ORIGIN.

ALTHOUGH the influence of heredity as a factor in the causation of certain forms of œdema, not of cardiac or renal orgin, was mentioned by Quincke in 1882, it was not until 1888, when Osler published the details of a case, that the subject attracted general notice. This was partly due to the position of Osler as a clinical investigator and partly to the exceptional circumstances which enabled him to obtain and to publish a full and accurate history of the patient's antecedents. Dinkelacher, a pupil of Quincke (1882), recorded the case of a matchmaker who had for years been affected with attacks of acute œdema and whose son, a child, aged one year, had suffered from the third month with the same affection, and in 1885 Valentin added the information that another son, then two years old, born subsequently to 1882, was also affected with similar attacks from the first week of life. The case reported by Osler is published by Dr. A. W. Fairbank of the Boston Hospital for Children in the *American Journal of the Medical Sciences* for May and he also adds details of other cases and personal observations. Through the fortuitous recollections of some of the members of the family, and especially the unimpaired memory of a great grandfather, aged 92 years, who had himself been affected for 74 years, a family history extending through five generations and involving 22 members was obtained of Osler's famous case. The characters of the affection in this family were the occurrence of local œdematous swelling in various parts of the body, the almost invariable association of gastro-intestinal disturbance—colic, nausea, vomiting, and occasional diarrhœa, and the strongly marked hereditary disposition. The genealogical table is as follows:—



♀ died aged 72 years.
♂
♂
♂ living at the age of 92.
By first wife.
By second wife.
Three children, all affected.
♂
♀
♀
Four children; one (a boy) affected.
♀ child.
♂
♀ died from œdema of the glottis.
Five girls; four affected.
Two boys.
♂
♀
Child aged 11 years.
♀ of 17 years, suffers from attacks.

Ricochon (1895) reports an instance of acute œdema, accompanied by colic, vomiting, meteorism, malaise, and febrile disturbance, as follows:—



♀ with attacks of œdema but without pain or vomiting.
♀ has attacks of œdema.
Several brothers with attacks of œdema.
Patient X. ♀ had acute attacks of œdema since childhood, affecting the face and extremities.
♂
♀ has chronic œdema of parts of the body.
♂ has similar attacks.
♀ died from tuberculosis.
♀ apparently healthy.

This patient X's attacks could be brought on with great suddenness by mental emotion. The attacks appeared on an average once a fortnight. Her mother had similar attacks from childhood and died at the age of 63 years from dropsy. Dr. Fairbank also cites individual cases observed by Schlesinger (1898), Wardrop Griffith of Leeds (1902), and himself and states that these instances taken from records of medical literature leave no doubt as to the influence of heredity in these cases of acute recurrent neurotic œdema. In a more chronic type of the affection as cited by Milroy[1] the family history of the disease could be traced over six generations, comprising 97 individuals, of whom over 22 per cent. were affected. Of these the third generation comprised nine individuals all affected and all the children of one father. No more curiously interesting affection exists than this, says Dr. Fairbank. Death occurs in some, almost invariably from œdema glottidis, but others who are affected with it may live to a good old age. Of the ultimate neurotic nature of the affection, concludes Dr. Fairbank, there can be no serious doubt.

THE DISTRIBUTION OF PLAGUE.

As regards the Cape Colony, the medical officer of health of the colony states that for the week ending April 23rd there were 2 cases of plague discovered at Port Elizabeth and that of 232 rats and 66 mice examined during the same period 82 rats and 7 mice were plague-infected. Plague-infected rodents were also found at East London, but of 343 rats examined in the Cape Town and Harbour Board area none was infected with plague. As regards the Mauritius, no case of plague was discovered for the week ending May 13th. As regards the Transvaal, a telegram from Lord Milner received at the Colonial Office on May 14th states that for the week ending May 14th the plague return was as follows: Total number of fresh cases reported since May 7th, 14—namely, 2 white persons and 12 coloured. Of the cases reported as plague 12 have been found not to be so, making the present total of suspected and proved cases 136—namely, 23 white persons and 113 coloured. Since May 7th the number of deaths reported is 2—namely, 1 white person and 1 coloured. At Hong-Kong for the week ending May 14th there were 28 cases of bubonic plague and 27 deaths from the disease.

KING EDWARD'S HOSPITAL FUND FOR LONDON.

IN another column we publish a letter from Mr. Hugh C. Smith, the chairman of the executive committee of the above Fund, together with a communication from Sir John Aird who generously offers to increase his annual subscription by £105 as a help towards raising the income of the Fund from investments and other permanent sources to £50,000 per annum. Before the anonymous donor to whom Mr. Smith refers gave his magnificent donation the assured income of the Fund amounted to about £36,000 per annum, being £14,000 short of the sum to which it was hoped that the assured income would have amounted by the beginning of this year. He therefore offered to give a capital sum producing one-third of the shortage provided that by Dec. 31st of this year capital enough to produce the remaining two-thirds should have been subscribed or provided for. This probably means that a further sum of about £310,000 still remains to be collected. Sir John Aird's generous contribution should certainly stimulate other donors and we earnestly hope that despite the increasing calls which have to be met—namely, rates and taxes—the people of these islands will do their utmost to help the metropolitan hospitals which benefit not only the people of London but those of the United Kingdom or even, we may say, of the Empire at large.

THE SPOROZOA IN RELATION TO DISEASE IN MAN AND ANIMALS.

THE eighth and concluding lecture on the sporozoa was delivered by Professor E. A. Minchin at University College, London on May 9th[1] It dealt with those sporozoa the affinities and place of which in classification are doubtful. Though difficult to classify, these forms are nevertheless of importance as disease-producing agencies. They include forms parasitic or chætopod worms (tubifex) and belong to the genus actinomyxon; the haplosporidia, which are sporozoa of small size and extreme simplicity of structure, which occur as parasites in rotifera; and the exosporidia, the lymphosporidia, and isolated species not placed in any group. The exosporidia include two remarkable forms—viz., amœbidium, a parasite which occurs on the gills and antennæ of crustaceans—and siedleckia, a somewhat similar organism which presents phenomena of multiplication and spore formation comparable to some of the lower algæ but which in other characteristics shows affinities with the gregarinæ—e.g., schizocystis. The lymphosporidia occur in the cœlomic fluid of crustacea and fresh water fishes and a lymphosporidium was recently ascertained to be the cause of death of American lake trout which had been affected and destroyed by epidemics of an hitherto obscure disease. The few isolated species of sporozoa which remain unclassed include a gregarine-like parasite which is found in the mesenteries, lymphatic glands, and subcutaneous tissue of the flounder and which has a special interest because gregarinæ do not occur in the aged 32 years, whose brothers and sisters suffered from hypochondriacal delusions or mental depression. Hitherto he had resisted the morbid impulses referred to, being well aware that these promptings, so foreign to his better nature, were subjective and abnormal. "The inclination to strike sometimes arose without any provocation on seeing a weapon and a person near each other. ...... He was in constant dread of doing something violent. ...... When closely interrogated he said the 'internal voices' or 'loud thoughts' [which impelled him] were in his head." He also had the fixed belief that his soul was lost and he had crude hallucinations of sight and hearing. He saw "flashes of light" before his eyes and heard "creakings and clankings" in corners of rooms. He was full of emotion and would burst into tears when describing his experiences and he was afraid of having to go to an asylum. He was treated with rest, a change of surroundings, tonic cold baths, and medication with bromides and belladonna and aperient tonics. After steady improvement he went away and under the stress of an accident and unfavourable circumstances he relapsed and became worse, so that he had eventually to be placed in an asylum. Emotional, affective, or phobic obsessions may constitute, says Dr. Shaw, almost the whole disease in cases of obsessional aberration (rudimentary paranoia). Perhaps the most typical of these is the fear of open spaces (agoraphobia). An excessive and unreasoning fear of death or of disease makes many persons take extraordinary, though really futile, precautions. Women are especially the subjects of such obsessions of fear of death or of infection. In some cases of morbid impulse the will is occasionally powerless to prevent its execution and the question of responsibility has to be decided. Psychologically, says Dr. Shaw, a species of dissolution appears to take place in the highest cerebral centres (those of control of the thoughts and emotions) in cases of obsession and morbid impulse. Toxic conditions, mental exhaustion, and indulgence in alcohol may cause exacerbation of symptoms by inducing freer liberati morbid impulses from the brain to the (impulsive acts). Treatment consis citement

rally made the richer and superior ption is thus encouraged. The shell of the white egg is stained in the simplest possible way, perhaps by immersion in a decoction of coffee berries or by means of an aniline dye. This resource may satisfy the eye, but, after all, there is probably not the slightest difference from the nutritive point of view between the naturally brown-coloured egg and the white one. There is most probably, however, an important dietetic difference between two eggs, the yelk of one of which is a very pale yellow colour and that of the other a rich, almost reddish, colour. It is a notorious fact that the country-produced egg may usually be placed under the latter description, while the egg produced by the hen who is under an unhealthy and limited environment shows an anæmic colour, generally a very pale yellow. The eggs of wild birds—as, for example, the plover—show a yelk of a rich reddish colour. The substance which contributes colour to the yelk of the egg is iron, just as it is iron which gives colour to the blood, and there seems to be little doubt that the iron compound in the yelk of the egg is of a similar nature to that of the blood. It is easily assimilated and eggs are regarded as a suitable food for the anæmic person, as they present a concentrated and generally easily digested form of nutriment rich in iron. The iron compound of the egg has, in fact, been termed a "hæmatogen," because it is probable that from it the blood of the chick is derived. The amount of iron in the yelk of an egg would appear to increase with the intensity of its colour and there can be little doubt that the maximum is reached in the richly coloured yelk of the egg produced by a fowl existing in healthy surroundings, for then its processes of nutrition would be working under very favourable conditions. As an

equipped and ablest general practitioners in our body are not in *possession of a doctor's degree.* We welcome therefore the opportunities that are afforded by our new universities. But it must be pointed out that such a boon to local students as the possibility of obtaining an M.D. degree makes the plight of the London student additionally hard seeing that he can only obtain a doctorate from his university upon terms that are arduous as compared with those exacted by many other universities.

THE LATE MR. ADRIAN HOPE.

THE death of Mr. Adrian C. F. Hope, which took place at St. Thomas's Home on May 10th after an operation for appendicitis, has caused profound regret, especially amongst those members of the medical profession with whom he has been associated at the Hospital for Sick Children, Great Ormond-street, London, W.C., of which he was secretary. Mr. Hope was the eldest son of Colonel W. Hope, V.C., and at one time held an appointment at the Bank of England. He afterwards became private secretary to the Governor of Ceylon and in 1885 he was appointed secretary to the Hospital for Sick Children—a position for which he was eminently suited by reason of his sympathetic, tactful, and courteous nature. The welfare of the little patients for whom Great Ormond-street Hospital was founded was the one great object to which he devoted his life and the important position which that hospital has taken among children's hospitals is due in no small measure to the energy which he threw into his work. To his initiative was due the Coronation bazaar which was held in aid of the hospital in 1902 at the Royal Botanic Gardens and opened in July of that year by Her Majesty the Queen. Apart from the historic character of the bazaar it was remarkable for the brilliancy and distinction of its patrons. The visitors included most of the well-known leaders of society, many representatives of our colonies, and several Indian princes. The sum realised

Dr. Haldane recommended the use of water j to keep down the dust. In the case of rock drilling the us water jets should be made compulsory by law and the sa legislation should obtain for blasting. Mr. Pengelly, a ju and a miner, supported the use of jets but another juror, a a miner, objected to water jets. The jury returned a verd that the deceased had died from pulmonary phthi apparently caused by the inhalation of dust and added t following riders :—

1. That in view of the large number of miners who have rece died in this district from the effects of dust inhaled during r drilling and other underground work, particularly in the Transv and also in Cornwall, we consider that special legislation for t purpose of dealing with this very grave source of danger to health urgently called for.

2. That copies of this resolution be submitted to His Majest Secretaries of State for the Home Department and for Colonial Affa

It is much to be hoped that the results of this inquest w inspire the Government to take action at once upon t matter. It may be that the use of water in a deep mi may lead to various difficulties as regards hygiene fro other points of view than the respiratory one. But wat rock drills are being used in the Simplon tunnel works an the particular drill—namely, that on the Brandt system—w exhibited at the *conversazione* of the Royal Society on th evening of May 13th, to which we refer more at length i another column. Pulmonary disease is so fatal to mine that where it is possible the water drill, which certain does prevent dust, should undoubtedly be used.

THE REGISTRATION OF NURSES.

THE question of the registration of nurses is temporaril shelved but it is one which must inevitably again call fo notice seeing that it provides a bone of contention betwee two influential sections of the nursing world. *We hold n* brief for either party, as will be evident from a perus of the annotations dealing with this topic which hav already appeared in our columns,[1] but we may appropriately summarise the evidence for and against the proposed alteration of the status of nurses in order that our readers may understand what is really in dispute. This object will be materially furthered by reference to two articles which have appeared in the *Nineteenth Century*, one in February last and one in the current (May) number. In the former Lady Helen Munro-Ferguson states the case for registration with some fulness, while the latter gives Miss Eva C. E Lückes, the matron of the London Hospital, an opportunity of presenting her views on the subject. At present, according to Lady Helen, the nursing profession "has no governing body, no standard of training, no corporate existence. Every hospital, whatever its size and standing, is a self-constituted training school." Everything depends on the matron who "may so legislate that her nurses will leave the hospital having seen but one department of work and remain, therefore, practically untrained in every other important direction." Under the present system there is no authority which is in a position to safeguard the interests of the public, and, on the other hand, nurses have "no fear of professional shipwreck to deter them from unprofessional conduct." The key of the position which Miss Lückes takes up is the opinion that the qualities of a good nurse are not capable of registration and this view is frequently reiterated in the article to which we allude. "Technical knowledge is only one, and that the least important, side of a nurse's qualifications," she says, and proceeds: "Where nursing is concerned the results of examination are specially misleading. A nurse may possess plenty of technical knowledge of her work and have no faculty for displaying this knowledge at examinations. ...... One of the most insidious injuries that registration would inflict upon future nurses would be to make the right women believe that if they could not pass such examination as may be required by a central board they must get their living in some other way." On one point we are entirely in sympathy with Miss Lückes, and that is in condemnation of the "pseudo-scientific young person who is more concerned with showing off her 'little knowledge' to the doctor and more interested in the 'case' than in the patient," but we do not quite see why registration should "tend to multiply this type indefinitely."

THE PHARMACEUTICAL SOCIETY OF GREAT BRITAIN.

THE annual dinner of the members of the Pharmaceutical Society of Great Britain and their friends was held in the Whitehall Rooms of the Hôtel Métropole on May 17th, when the President of the society, Mr. S. R. Atkins, occupied the chair He was supported on his right by Sir William S. Church, the President of the Royal College of Physicians of London, and on his left by Mr. J. Tweedy, the President of the Royal College of Surgeons of England. As might have been expected the speakers during the evening referred chiefly to the subjects uppermost in pharmacists' minds just now—namely, the new Poisons Bill shortly to be introduced into Parliament and the Pharmacy Bill. The former proposes to relax to some extent the present conditions under which poisons are sold and to extend the power of selling certain of them to unqualified persons. Pharmacists regard this Bill, not without some excellent reasons, as practically a proposal to introduce free trade in poisons. The Pharmacy Bill is a measure seeking to deal with companies practising as pharmacists. There can be no doubt that pharmacists are being seriously and unfairly handicapped by the pushful action of the unqualified trader. This is a serious menace to the dignity and interests of a hard-working profession, besides which it is obviously desirable that the public should be protected against unqualified trading. Strong and persistent concerted action is what is required, urging upon the Government the importance and need of the reforms just indicated. Mr. Thomas Lough, M.P., in replying to the toast of "The Houses of Parliament," expressed the belief that the Pharmacy Bill had been well received and he was strongly in favour of legislation being introduced with the view of checking the sale of poisons by other than duly qualified persons and all druggists' shops should, he contended, be managed by duly qualified men. Sir M. M. Bhownaggree, M.P., promised his support. In proposing the toast of "The Medical Profession," the President hoped that the help always willingly accorded by the Pharmaceutical Society in the preparation of the Pharmacopœia would receive official recognition. Sir William Church, replying to this toast, congratulated the pharmaceutical profession on the high standard of purity which had been obtained in regard to drugs and he hoped that he might count on securing the help of pharmacists towards introducing a system of control for the standardisation of sera. At present there was a great difficulty in obtaining serum preparations made to a uniform standard. Mr. Tweedy congratulated pharmacists on the improved status of their calling and said that the timely aid which the pharmacist always afforded, in a quite unostentatious way, in emergency cases was a tribute to their humanity and skill. Dr. J. Wilson Swan, F.R.S., then proposed the toast of "The Pharmaceutical Society," the President replying. The proceedings closed with the toast of "The Guests." Amongst those present were several Members of Parliament and the scientific societies were represented by their respective presidents.

MEDICAL SOCIETY OF LONDON: ANNUAL ORATION AND CONVERSAZIONE.

THE annual conversazione of this society was held on May 16th and there was a large gathering of Fellows. After a reception by the President, Dr. F. de Havilland Hall, the annual oration was delivered by Sir Isambard Owen who chose as his subject the Future of Medical Education in London. It is printed *in extenso* at p. 1399 of this number of THE LANCET. A vote of thanks was proposed by Dr. J. Kingston Fowler, seconded by Mr. A. Pearce Gould, and carried with acclamation. Afterwards music was provided by the string band of the 2nd Life Guards.

THE annual report and statement of accounts for the year 1903 of the Medical Defence Union have just been issued. The announcement is also made that the annual general meeting of the members of the union will be held on Thursday next, May 26th, at 5 P.M., at the Medical Society's rooms, 11, Chandos street, Cavendish square, London, W. Referring to the action taken by the union in regard to the scheme of the British Medical Association for medical defence the report of the council of the Medical Defence Union states that many letters have been received from members of the union in all parts of the United Kingdom in which cordial expressions of support and agreement with the action taken by the union are to be found.

THE net value of Sir Henry Thompson's estate has been sworn at £223,748, this being one of the largest fortunes left in recent times by a member of our profession. A certain, and not small, portion is represented by a legacy. Sir Henry Thompson desires in his will that his trustees shall send his portrait by Sir John E. Millais to the trustees of the National Gallery and that his autobiography shall not be published until ten years after his death.

---

[1] THE LANCET, April 2nd, p. 946; 9th, p. 1009; and 23rd, 1904, p. 1140.

Mr. Howard Marsh, professor of surgery in the University of Cambridge and consulting surgeon to St. Bartholomew's Hospital, will deliver the Hunterian lecture at St. George's Hospital on Wednesday, May 25th, at 8 30 P.M., his subjects being (*a*) Intermittent Hydrops of the Joints and (*b*) the Influence of Growth on Deformities. All members of the medical profession are invited to attend.

A DINNER will be given to Mr. Chamberlain in recognition of his eminent services to preventive and tropical medicine at the Criterion, Piccadilly Circus, London, W., on Thursday, June 30th, at 7.30 P.M., by the Royal Institute of Public Health. Applications for tickets (one guinea) should be made to Mr. James Cantlie, M.B. (honorary secretary), at 19, Bloomsbury-square, W.C.

THE official summary of births and deaths and their causes in the principal towns of England and Wales during the year 1903 has just been issued, 76 great towns and 103 smaller towns being now included in the official purview of Somerset House.

THE death occurred on Monday last, May 16th, of Professor Etienne Marey, the inventor of the sphygmograph and famous for his physiological work in illustration of the cardiac and respiratory movements.

H.R.H. Princess Christian of Schleswig Holstein will be present on Saturday, May 28th, at the annual meeting of Guy's Hospital Ladies' Association, of which she is president.

WE publish below an appreciation by Professor William Stirling of the zeal, energy, and great scientific acumen of the late Professor Wilhelm His.

Mr. David Charles Lloyd Owen has been appointed an Esquire of the Order of the Hospital of St. John of Jerusalem in England.

PROFESSOR WILHELM HIS,

K. S. GEHEIMER RATH; PROFESSOR OF ANATOMY IN THE UNIVERSITY OF LEIPSIC.

BY WILLIAM STIRLING, M.D., D.SC. EDIN., LL.D.,
PROFESSOR OF PHYSIOLOGY AND HISTOLOGY AT, AND DEAN OF THE MEDICAL FACULTY OF, THE VICTORIA UNIVERSITY OF MANCHESTER.

(*Being a tribute of regard and esteem for the man, his work, and his beneficent influence.*)

FULL of years and honours, after a life of devotion to scientific pursuits, Wilhelm His, after a long period of suffering nobly borne, died at Leipsic on May 1st. Born on July 9th, 1831, in Basle, His pursued his medical studies there in 1849 for one session; he then studied in Berne, under Theile and Valentin, and then (1850-52) in Berlin, where he was a pupil of Johannes Müller and also of Robert Remak. His was much impressed with a lecture on development given by Remak embodying the results of his own observations. He afterwards studied at Würzburg (1853-54) where Virchow was then professor. Virchow, it may be remembered, was forced to leave Berlin and Würzburg was only too pleased to have him from 1849 to 1856 when repentant Berlin recalled Virchow. For three sessions His studied under Virchow and in 1856 he published his "Beiträge zur normalen und pathologischen Histologie der Cornea" (six plates), which was dedicated to Virchow. After studying at Prague, Vienna, and Paris His in 1856 became a *privat docent* at Basle under Meissner and succeeded him in 1857 as professor of anatomy and physiology when Meissner was called to Göttingen. Indeed, it was only a year or two ago since Meissner retired from Göttingen to be succeeded by Verworn. His remained in Basle until 1872, when largely through the influence of Carl Ludwig he was called to Leipsic to fill the chair of anatomy. On the retirement of Ernest Heinrich Weber his chair was divided, Ludwig becoming professor of physiology and His professor of anatomy. Thenceforth Ludwig and His worked together and they soon made Leipsic the centre from which emanated great works in their respective subjects and to which were attracted numerous pupils, both from the Fatherland and Europe, and, indeed, from all over the world, who were anxious to study under such distinguished masters.

For over thirty years the names Leipsic and His have been indissolubly linked together. Early in the "seventies" W. Braune was associated with His as professor of topographical anatomy. The death of Braune in 1892 was a sore blow to His and an irreparable loss to anatomy. The scientific contributions of His exceed 100 in number. Amongst the earliest were his papers on the cornea and its corpuscles; then followed his studies on adenoid tissue and the lymphatic glands, including those of Peyer and other glands associated with the lymphatic system. He was the first to pencil away the leucocytes and thus reveal the adenoid structure. His studies on the lymphatic system extended to the lymphatics present in membranes and to those of the central nervous system, indeed, the perivascular spaces of His still bear his name. Some of these researches were done jointly with his friend, Th. Billroth, who at that time was professor of surgery in Zürich. Let anyone refer to the beautiful plates on the structure of the lymphatic and thymus glands in the early numbers (1861-62) of the *Zeitschrift für Wissenschaftliche Zoologie* and he will find pictures unsurpassed by any at the present time.

A little known but valuable document is that "Ueber die Entdeckung des Lymphsystems," in memoriam Ernesti Gottlobi Bosei, published in 1874 at Leipsic by His. It gives one of the best and most accurate accounts of this historically interesting question, every statement being accompanied by a reference to the original source. On purely descriptive anatomy—apart from his series of models—his great work, jointly with L. Rutimeyer, is the "Crania Helvetica" (1864). The year 1865 marks a new departure and one that led him to his great life-work on development and embryology—viz., "Ueber den Bau des Säugethiereierstocks." This led to "Die Häute und Höhlen des Körpers" being studied from an embryological point of view.

His held in high estimation Robert Remak of Berlin. His was specially impressed with Remak's view that the true glands had a mixed origin, that while their vascular tissue arose from the mesoblast their epithelial cells were derived from the other two membranes. It was not this, however, which led His to his "life work." He reached that by a roundabout channel and we may take it as beginning in 1865 with his work on the ovary, and this work he pursued with assiduous labour and marvellous and enduring success for nearly 40 years. In "Die Häute und Höhlen des Körpers," a small quarto of 34 pages published as an "Akademisches Programm" in Basle in 1865, he refers to the fact that since the time of Bichat—nearly half a century—no comprehensive monograph had appeared on these important topics. His, however, treats the subject from the point of view of the development of the several organs and the origin of the tissues from the layers of the embryo, and he refers again to Remak's theory of the origin of the central nervous system from the epiblast and the peripheral nerves from the middle layer of the embryo. Before great progress could be made and before the origin of the nervous system could be fairly worked out, a microtome had to be invented and the technique much improved, and this His did His was the first to use a microtome which enabled him to prepare serial sections in 1866. His views on the archiblast and parablast were strongly opposed. After relinquishing part of his parablastic theory and modifying it in 1881, he in 1900 published "Lecithoblast und Angioblast der Wirbelthiere," wherein, with most other observers, His recognised the separate origin of the connective substance and the "Anlage" of the vessels. The former he derived from the mesoblast; the latter arises from the extra embryonal and peripheral mesoderm and grows from this later into the embryo. His had a surer ground when he studied the part played by mechanical processes

PROFESSOR WILHELM HIS

in determining the foldings and curvatures that occur in developing organs and he may be regarded as one of the chief advocates for what is now known as "the mechanics of development." His's semi-popular work published in 1874 and thrown in the form of letters dedicated to his friend Ludwig—"Unsere Körperform, und das physiologische Problem ihrer Entstehung"—set forth this view. He returned to the subject in 1894 (in the *Archiv fur Anatomie und Physiologie*) in a classical paper on the Mechanical Fundamental Processes concerned in the Moulding of Form. Beginning with the foldings and anfractuosities known to the geologist, His, by means of elastic plates, modeller's wax, strips of paper, leather, and various other materials, shows what an important part unequal growths on the one hand and pressure on the other exert in moulding the form and flexures of the central nervous system.

When Muller's *Archiv* ceased and when du Bois Reymond founded its continuation as *Archiv fur Anatomie und Physiologie* His took over the editorship of the anatomical part and nearly in every number from 1877, the year of its foundation, down to 1901 we find one or more papers from his pen and pencil dealing with development in all its aspects, from the unfertilised egg to the successive changes that occur in the embryonic layers from their appearance onwards, the development of special organs like the lungs, thymus, and thyroid, but above all the early stages of the nervous system. More especially important is his work on the human embryo. His large folio, "Anatomie menschlicher Embryonen" (Parts I., II., and III, 1880-85), is a monument of exact draughtsmanship and a mine of accurate detail of the early stages of the human embryo. His studied the early stages of development in the chick and in bony and other fishes. In his great work on the human embryo for the first time we have an accurate picture in word, portrait, sections, and models of the early stages of development. He meant to fill in the picture by giving the development of the individual organs but was unable to accomplish all his desires. Undoubtedly the most important are his numerous researches on the nervous system, some published in the *Archiv* and others in the Transactions of the Saxon Academy of Science. In his latest papers he studies the morphology of the total nervous system and suggests new views derived from a study of comparative development and deals with the inter-relations of the cell elements themselves. In the *Archiv* his numerous papers on the nervous system are specially important. In 1889 he set forth his researches on the "neuroblasts" and their origin in the embryonic cord. About 1886 he established a view which he had long held that the axis cylinder is a process of a nerve cell and he found that the axis cylinder of the anterior spinal nerve roots grew out from the cord while those of the posterior or ventral root grew into the cord secondarily from the spinal ganglia. It is easy to see how these results bear upon the more modern researches of Golgi, Cajal, and others.

His was one of the chief founders of the Anatomische Gesellschaft and was the chief mover in connexion with the scheme for unifying anatomical nomenclature. The commission was formed in 1889 and His was able to report in 1895. In 1876–78, along with Braune, he founded the *Archiv für Anatomie und Entwicklungsgeschichte* and was its editor. He became editor of the anatomical part of the *Archiv für Anatomie und Physiologie.* The magnificent and extensive institute for anatomy was built under his direction and formed the pattern of many others. From the "seventies" onwards Leipsic was the Mecca of young investigators desirous of prosecuting researches under Ludwig and His. He was always desirous of visualising his work and hundreds of models of embryos in all stages were accurately made to scale. The importance of the His-Steger models, which represent accurately the position, size, and relations of the viscera, is such that they are to be found in every medical school. New methods had to be devised to get such accurate results. His fully describes the "situs viscerum" in the *Archiv* of 1878. His reconstructions preceded the method devised by Born.

When the new Johanniskirche was being built in 1894 it was desired to find the bones of Johann Sebastian Bach in order to re-inter them in a suitable fashion. It was known that Bach, aged 65 years, was buried in a shallow grave and after much search His found an oaken coffin containing a skull that closely corresponded to the portraits of Bach. He [illegible]

of the Saxon Academy of Sciences.

When we survey the immense amount of original work which His accomplished we can well say that "prodigious" was his energy and his application and untiring was his zeal. When we remember that all this was accomplished along with the active performance of the duties of a professor of anatomy in a great school of medicine, we can only wonder how it was done. His was a clear and explicit lecturer, a draughtsman of the highest ability, and marvellously beautiful were the pictures which he built up before his audience in the lecture theatre. All the drawings—and they were legion—for his various papers and monographs were drawn by his own hand either directly or by means of his embryograph. Early he saw the value of photography to the anatomist and histologist and a large photographic department formed part of the outfit of his laboratory.

Many are the anatomists who studied under him. In our own country we may mention Symington and Gemmill and across the pond Mall, Clark, Flint, and MacCallum. Endowed with a charming personality and a manner at once suave and inviting His attracted round him groups of young investigators eager to work under him. He was always ready to help the beginner and to guide him by his wise counsels. For several years and on many occasions it was the writer's privilege to see much of His and to learn a great deal from him. Perhaps this may prove an excuse for trying to write something on a subject not my own in memory of one who "im Wort und Bild" has left an indelible impress on embryology and morphology and by his researches broadened their foundation, extended their domain, and by so doing has left behind a record of imperishable work and many, many friends and pupils to mourn their loss.

THE

GERMICIDAL EFFECT OF SEPTIC TANKS AND BACTERIAL FILTERS, AND THE BACTERIOLOGY OF SEA-WATER AND OF SHELL-FISH.

SECOND NOTICE.[1]

IN our first notice of Dr. A. C. Houston's report to the Royal Commission on Sewage Disposal we dealt with the bacteriology of the upper and lower Thames, of the London sludge and effluent, and of the waters of the Barrow Deep. In this notice we shall touch briefly upon the remaining subjects treated of in the report. A detailed and exhaustive notice would make too much claim upon our space and therefore an indication of the contents of the work and of the conclusions deduced from the experiments will probably be most acceptable to our readers.

The Inoculation of Sewage with the Bacillus Pyocyaneus and the Subsequent Isolation of that Organism from the Sewage Effluent of Certain Biological Processes.

It is one of the commonest fallacies of the present day to assume that in the septic tank and bacterial filter a panacea has been found for all the evils with which sewage is associated. If, therefore, it is alleged, all our sewage can be subjected to one or other of such processes all will be well. This is a very common attitude on the part of those who seek to bring into operation the provisions of the Rivers Pollution Acts with respect to estuaries. But it is now many years—indeed, in the early days of the Exeter process—since experimental work raised the suspicion that this view was utopian and suggested that immunity from water-borne disease was not to be sought for in this direction. Those who still cling to these old beliefs will do well to refer to Dr. Houston's recent investigations in this direction. The cultures used in these experiments were those of the bacillus pyocyaneus and it is as well to point out that this organism has at times been found in sewage to which it has not been intentionally added. But this fact does not, as Dr. Houston observes, seriously invalidate the instructive results of his experiments. Dealing first with a continuous filter it was found that this organism when added to the sewage in enormous numbers appeared in the effluent within ten minutes of the starting of the experiments and that the virulent bacillus pyocyaneus was isolated from samples of the effluent obtained five hours afterwards. Dr. Houston is apparently afraid that erroneous conclusions may be drawn from these experiments and he therefore hastens to add the inferences which he draws—i.e., "that a continuous filter, although capable of yielding very good results chemically and, relatively speaking, good results bacteriologically, cannot be trusted in the case of the discharge of the effluent into a drinking-water stream to remove the element of potential danger to health." We do not quite follow Dr. Houston as to the precise nature of the relatively good bacteriological results. Subsequent experiments with the same filter gave somewhat similar results and they showed that the organism in question could be detected in the filter up to the tenth day. When experiments were made with a septic tank and contact beds it was found that the bacillus pyocyaneus had no difficulty in passing through the septic tank and that this organism appeared in the septic-tank liquor within two and a half hours from the starting of the experiment and that it appeared in the effluent from the contact beds directly such effluent was drawn off. The fact of its speedy appearance in the effluent of the septic tank tends to show that, in this instance at least, the sewage did not remain in the tank for anything approaching the time which each particle is supposed to take in passing through, and it would seem likely that the organisms found in the effluent had "streamed" directly through the tank. This rapid appearance of organisms in the effluent from biological processes of sewage treatment is a disturbing feature of such methods, and although Dr. Houston tells us that in no instance was there any indication of multiplication it does not appear, so far as we are able to judge by the records, that there was any material reduction.

---

[1] The first notice was published in THE LANCET of May 7th, 1904 p. 1299.

It would have been instructive had some experiments been carried out with regard to the reduction in organisms brought about by processes of chemical precipitation, and doubtless the Royal Commission is proposing to do some work in this direction. Moreover, it is desirable in the interest of streams used for drinking water or for shell-fish culture that the effect of sand filtration in the case of the effluents from biological processes should be tried or that some other method of bringing about a relatively sterile effluent should be discovered. Land treatment is not practicable in all places and what certain municipal authorities will wish to know from the Royal Commission is how, assuming suitable land to be not procurable, they may most economically set to work to produce an effluent in which the number of organisms present in the original sewage has been very materially reduced. The Royal Commission will forgive us if we suggest that in our opinion future work might be directed to this end. At present we seem to be some distance from the desired goal.

The Bacteriology of Unpolluted Sea Water.

The Royal Commission has performed a valuable service in promoting a series of experiments in connexion with this subject. Hitherto but little has been known as to whether or not organisms the presence of which have been held to condemn water and shell-fish were really natural inhabitants of both, and it is this absence of knowledge which has placed a powerful weapon in the hands of the opponents of what may be termed unscientific bacteriology. In so far, however, as surface samples are concerned Dr. Houston's experiments have greatly cleared the air. The samples of water examined in his laboratory were procured for him by the well-known bacteriologist, Dr. M. H. Gordon, from the west coast of Scotland during July, 1903, and it is a matter of very considerable interest to find that 34 out of the 35 samples of water examined yielded negative results *quâ* bacilli coli, even when dealing with 100 cubic centimetres of the water. The remaining sample yielded a positive result with 10 cubic centimetres, but not with one cubic centimetre and Dr. Houston must have been very gratified to learn subsequently from Dr. Gordon that this sample was the only one which was collected at all near the shore.

As regards the bacillus enteritidis sporogenes none of the samples yielded a positive result with 10 cubic centimetres of the water. These experiments certainly go very far to show that neither bacilli coli nor bacilli enteritidis are to be found in any numbers at the surface of the ocean in places removed from land, and this notwithstanding the fact that, as Dr. J. W. H. Eyre has recently shown, birds and fishes, which were procured for him through Dr. H. T. Bulstrode's intervention from localities remote from land, were found to contain bacilli coli in abundance. But as Dr. Houston has pointed out in connexion with the bacteriology of the sea water in the Barrow Deep it is likely that organisms voided at or near the surface gradually sink to the bottom and, as he thinks, there undergo destruction. Clearly, however, to complete the research it is desirable that samples of water from near the sea bottom should be examined as also should samples of sand and mud taken from the bottom itself. This is the more important seeing that the shell-fish to which attention was mainly directed in the report before us have practically no alternative but to remain on the bottom. This criticism, however, in no way detracts from the excellent work done by Dr. Houston in the case of surface samples.

But having got these results Dr. Houston was evidently tempted to set up a standard in view, as he points out, of the range of difference between 100,000 bacilli coli per cubic centimetre in sewage and no bacillus coli-like microbes of any sort in 100 cubic centimetres of unpolluted sea water. But he adds that at the present time the attempt to lay down *absolute* standards is not justifiable. Before this can be done further study must be made. Moreover, the assumption that the bacillus coli is directly injurious "seems unwise, if not unwarrantable, in the present state of our knowledge," and he thinks that the only fair attitude to assume is that the bacillus coli is an *indirect* index of potential danger to health. In his view although it may be convenient to measure the degree of danger by the numerical abundance of bacilli coli nevertheless "neither the epidemiologist nor the chemist, nor even the bacteriologist can place a 'disease value' on any given pollution." Dr. Houston then devotes a considerable space to the discussion of these numerical standards and he sums up his conclusions in a series of propositions. Of these the one which has most bearing upon the subject of this article and upon administrative measures generally is the following: "That in all but obvious cases of contamination *degrees* of pollution need to be measured by the bacteriologist *who should interpret his results in the light of local observations and epidemiological considerations.*"

The Bacteriological Examination of Samples of Water and of Oysters obtained from the Helford and Penrhyn Rivers in Cornwall.

Dr. Houston selected these two estuaries for detailed examination because the Helford river is one of the purest estuaries to be found in England, whereas the waters of the Penrhyn river have ample opportunities at places of becoming specifically polluted. We cannot, we fear, follow Dr. Houston's work with regard to these two estuaries in detail. It is like all his work—eminently thorough in character and cautious in inferences. Dr. Bulstrode regarded the Helford river upon general topographical grounds as one of the very purest in the country and Dr. Houston from his own observations is practically in agreement with him upon this point. Dr. Houston also agrees that the Penrhyn river is an undesirable place in which to fatten oysters for the market. The first three samples of the Helford river which were taken at different parts of its course yielded no bacillus coli-like microbes in ten cubic centimetres of any of the samples and the bacillus enteritidis test also yielded negative results. These preliminary negative results were, as Dr. Houston remarks, in *complete agreement* with the *topographical features* of the Helford river. But samples taken later in the year were not equally satisfactory and it was found that in one experiment eight out of 25 samples—i.e., 32 per cent.—contained bacilli coli or bacillus coli-like microbes in one cubic centimetre of the water but not in 0·1 cubic centimetre. Whatever may be the meaning of these variations—whether, for instance, there may be some seasonal law at work or whether in this latter case there had been some recent pollution as from a yacht or from some bacillus coli bearing fish or animal other than man—they suggest repeated examinations of a water before a definite conclusion can be arrived at. They also indicate how great may be the injustice done, whether to the public or to the fishing industry, by hasty generalisations from those assuming that the bacteriology of water and of shell-fish has reached a final stage in which dogmatic statements can be made concerning an isolated sample of water or of shell-fish.

As regards the presence and number of bacilli coli in estuarial waters at different points we have already discussed the interesting conclusions arrived at by Dr. Houston as the result of his work in the Thames estuary, results which we agree with him are most instructive and hopeful. But with his customary love of fairness Dr. Houston furnishes on

p. 310 of his report a passage from a recent report made to the Massachusetts State board of health by Mr. H. W. Clark and Mr. Stephen Gage. This passage, which we reproduce, has about it a suggestion that bacilli coli may in their voyage down a river actually increase rather than decrease. Indeed, it is possible that bacilli coli obtained from places some distance from a sewer outfall may be merely the offspring of those which left the sewer, and this would appear to be the more likely in estuaries such as the Thames, where the sewage liberated on one tide oscillates up and down the river for days until parts of this "sewage zone," as it has been called, are gradually displaced seawards by the fresh water coming down from the upper valley of the Thames. If, as is obviously conceivable, bacilli coli undergo multiplication in presence of certain flora which may promote their reproduction, it is equally conceivable, although we are aware that certain experimental work points to the opposite conclusion, that the enteric fever organism also may again, under certain and unknown conditions, multiply. If this be so, do those organisms which multiply outside their natural habitat retain their pathogenicity? The Massachusetts passage is as follows: "In a table following it will be noticed that of the samples of clams taken at known distances from a sewer outlet, the greatest percentage giving positive tests were collected one-half to three-quarters of a mile from this outlet. The water samples collected from one-eighth of a mile to one and five-eighths miles from the sewer outlet gave a greater percentage of positive tests for B. coli. Those collected at a distance of one-fourth to one-half a mile also gave a greater percentage of positive tests for B. coli than did the samples collected nearer the outlet."

The Bacteriology of the Oyster.

Although within the last ten years or so a considerable amount of work has been done in the direction of ascertaining the flora of the oyster it cannot be said that such work has proceeded altogether upon scientific lines. The essential basis for any legitimate inferences has not been determined, and without such a basis all deductions from the discovery of bacillus coli, bacillus coli-like organisms, or bacillus enteritidis sporogenes are practically valueless. It has not hitherto been conclusively determined whether or not these organisms are to be found in oysters procured from localities altogether remote from pollution by sewage of human origin. Here, again, the Royal Commission through Dr. Houston has thrown very considerable light on the problem. Dr. Houston's researches render it very doubtful whether oysters procured from positions remote from land influences do as a matter of fact contain bacilli coli or bacillus coli-like organisms. His experiments thus far point to a negative conclusion as regards what may be termed uncontaminated deep-sea oysters, but there would appear to be some question whether the absence of these organisms may not be a question of season and not a constant feature. Having regard to the seasonal behaviour of certain diseases which are known to be associated with micro-organisms it is desirable to be cautious in drawing inferences and it will be interesting to see the result of Dr. Houston's further researches in this direction.

But for the moment the most instructive result of the investigations upon the bacteriology of the oyster is that bacilli coli or bacillus coli-like organisms were found in practically all the oysters which were examined and which had been procured from even the purest layings around the English littoral. The fact that these organisms have not been constantly found in the past is apparently to be accounted for by the varying distribution of the organisms in the body of the oyster. If, for, instance, a pipette be taken and thrust more or less at random into the body of the oyster the amount of oyster substance and fluid withdrawn may be found devoid of either of the organisms in question. It would appear that in this manner are to be explained some of the negative results which were obtained in 1896 with oysters which were procured by Dr. Bulstrode from as near as possible to sewer outfalls but which were regarded by the bacteriologist to whom they were sent as wholesome molluscs. But Dr. Houston, appreciating the possible fallacy of this method, adopted the plan of examining the whole contents of the shells, and still further to guard against error he worked also with a *mixture* of ten oysters. His result shows, in his own words, "that B. coli or coli-like microbes can not only be practically always isolated from a *mixture* of ten oysters derived from layings which, judged from the topographical point of view, would be considered either above suspicion or at least reasonably secure from pollution, but also that such microbes can usually be isolated from each *individual*, or at all events from a great majority of the ten oysters experimentally tested."

Another very instructive point brought out by Dr. Houston's experiments is that the oysters almost invariably contain a much greater number of organisms per cubic centimetre of substance or liquor than is the case with the water collected above the oyster layings. Oysters examined from various sources differed materially as to the number which they contained of organisms which responded to all the tests to which bacilli coli isolated from the human intestines respond. For example, of oysters procured from West Mersea only 20 per cent. yielded what are called typical bacilli coli, a fact which shows how very misleading a test based solely upon typical bacilli coli is likely to prove. If the oysters which furnished the 20 per cent. had been by chance omitted from the oysters collected it is conceivable that an absolutely negative result might have been procured. But in the next ten oysters taken from the same source all ten contained typical bacilli coli. Again, in the case of ten oysters taken from the estuary of the Crouch *all* proved negative *quâ* typical bacilli coli, whereas in the case of a second batch from the same source no fewer than nine of the ten oysters contained typical bacilli coli.

In summing up the results obtained with regard to what are certainly some of the layings most remote from the risks of pollution which exist in England Dr. Houston adds: "To suggest, therefore, that the oysters from these layings are impure in the sense that they are a source of danger to

to accept what to some bacteriologists must be the logical outcome of his researches. He maintains, therefore, a somewhat agnostic attitude and while not affirming that the conclusions of the topographist are to be regarded as final he hesitates to make such a sweeping condemnation as would, we gather, be made by some bacteriologists—if they maintained a consistent attitude—upon the results obtained. Dr. Houston's attitude is with respect to this question of oysters somewhat similar to that which he adopted with regard to the water of the Thames in the neighbourhood of the intakes of the London drinking water. He is uncertain as to what value to attach to the testimony of *experience* and here he will find many sympathisers among those who approach the subject not exclusively from a bacteriological standpoint.

It will be said by some that the general outcome of Dr. Houston's elaborate research is disappointing, but from a purely scientific point of view, as also from an administrative standpoint, the results are, we think, eminently satisfactory. Dr. Houston has shown that the dimensions of this problem are such that at present dogmatic assertions cannot with justice to either side be reasonably made as the result of bacteriological examination alone, and in the interest of health it is surely an enormous advance to be delivered from a dogma for which there is no sufficient foundation We are quite sure that no bacteriologist would wish to jeopardise the public health or even an industry upon which many lives depend without being satisfied that the basis of his action was beyond dispute. We ourselves regard Dr Houston's work as most valuable and if, as it were, it sets up a standard of excellence which other workers in the same field strive to attain a very material advance in the science of bacteriology will have been made. That there is *still much to* be learnt as regards the bacteriology of shell-fish before dogmatic statements from the examination of one sample can be made is clear from the Massachusetts report already referred to. In this report it is stated that "the ability to demonstrate clearly the presence of a specific sewage organism such as B. coli is an invaluable aid in determining the question of purity or pollution." The fact that the presence of this bacillus *in large numbers* is an *aid* in doubtful cases may, we think, be conceded, even although the Massachusetts report adds that *in many samples from polluted sources bacillus coli has not been found in either shell, water, or intestine* (the italics are ours).

To sum up the situation it would, we think, be difficult to join issue with the recent report of the Royal Commission on Sewage Disposal when it says in Section 94: "Although we consider that the bacteriological examination either of sea water or shell fish, even if carried out in a quantitative as well as a qualitative manner, cannot at present be recommended as a matter of routine for the purpose of distinguishing unsafe foreshores, layings, ponds, &c., the result so far obtained shows great promise that by further inquiries a way will be discovered by which the elements of danger may be defined with much greater accuracy than is at present possible and it is in our opinion most important that researches in this direction should be continued."

We thoroughly agree with this recommendation which we hope will be followed by the Rivers Board, the creation of which the Commissioners advised in their third report, but we trust that the first act of the Rivers Board will be to close those layings, ponds, and pits which are *obviously* liable to pollution and the existence and surroundings of which have been well known since Dr. Bulstrode made his report to the Local Government Board so far back as 1896.

THE BRITISH MEDICAL ASSOCIATION AND MEDICAL DEFENCE.

A MEETING of the South-West (Wandsworth) division of the British Medical Association was held at the headquarters of the 4th V.B. East Surrey Regiment, St. John's-hill, Clapham Junction, London, S.W., on May 12th, to consider the scheme of medical defence as prepared by the medical defence committee of the Association. Dr. M. G. **BIGGS** presided and the number of members of the British Medical Association belonging to the division who attended the meeting and went to the poll upon the important question submitted to them was under 30.

Dr. **BIGGS** commenced the proceedings with a brief speech, recapitulating the situation and pointing out that there were two questions before them, which should be taken separately: (1) Is it desirable for the British Medical Association to take up medical defence? and (2) Is the scheme which has been prepared to that end by the medical defence committee of the Association a sound one? He decided to rule out of order the discussion of the scheme until the first question had been settled and voted upon and only divisional members would be allowed to vote.

Mr. G. **WALKER** (Wimbledon) then proposed that the British Medical Association should take up the scheme of medical defence, expressing himself strongly upon the advisability of gaining the experience and coöperation of the existing societies for medical defence.

Dr. S. **VERDON ROE** seconded the proposal.

Dr. A. G. **BATEMAN**, secretary of the Medical Defence Union, then addressed the meeting by the invitation of Dr. Biggs. He said:—

I am here by your courtesy, not to discuss the scheme, because I have nothing to do with that, but to explain the attitude which the Medical Defence Union has taken up in reference to this matter. The position has been made perfectly clear to our members and also, I think, to a great number of the profession who are members of the British Medical Association, because we issued a circular on March 3rd which was sent out to all our members and which was published in the *British Medical Journal* and commented upon in THE LANCET. The Medical Defence Union exists as a company limited by guarantee and could not in any circumstances merge or amalgamate itself into any other company or society but must exist as a separate entity, unless wound up voluntarily or compulsorily under the Companies Acts. The circular suggested "that to wind up and liquidate a financially sound and successful company, which has done for 19 years, and is steadily doing excellent and valuable work, not only for its members but also for the medical profession generally, would be a waste of the funds of the subscribers, involving, as it would, large expenditure and a needless sacrifice of the best interests of its members." This point has been much criticised. We have been asked in what way our expenditure would be involved. This is the way. In a society like ours of a medico-legal character we are occasionally served with writs on behalf of our members. Supposing the writ came into the office to day and we commenced to wind up to-morrow we should have to retain the funds in the hands of the liquidator to carry through the whole of the expenses in connexion with that case until its finish. Now, as I have personal experience it takes some time from the issue of a writ to the conclusion of the case. In this last fortnight we concluded a case the writ for which had been issued two years previously. The circular also said "that the union includes numerous practitioners who are not members of the British Medical Association who if the Medical Defence Union were wound up would either be cut off from defence and protection or would have to regain the protection now afforded them by becoming members of the British Medical Association and of its medical defence department at a cost of 35s. per annum," instead of 10s. per annum. I would ask you to remember in reference to our point of view that even in Wandsworth division there were 200 practitioners in this area of whom only six belong to the British Medical Association according to the last returns. The reason given for the new departure of the British Medical Association is that there should be one organisation only for medical defence, instead of, as at present, two or more. This, the council of the union desired in its circular to point out, would not necessarily follow even if the scheme were carried out, as it would not prevent members of the [illegible] present scheme from again forming [illegible] Association. The council has receiv[illegible]nbers in all parts of the country, not only endorsing everything it had said and done, but stating that if the council did wind up the union they would form a new Medical Defence Union, and that rather than give up their membership of the union they would give up their membership of the British Medical Association. I am not here in antagonism to the British Medical Association. I have been a member of the British Medical Association for many years and have served [illegible] All the members of our council are [illegible] Association and many of the members [illegible] n of the council and the committee of the British Medical Association. Therefore, the line which we take up is not antagonistic to the British Medical Association itself but is antagonistic to a scheme which if carried through would make a monopoly of medical defence. We think that healthy competition is better.

Sir **VICTOR HORSLEY**, speaking also by invitation, said:—

Dr. Bateman has referred to the circular of the Medical Defence Union, my connexion with whic [illegible] the utmost pleasure an[illegible] scheme and many of Dr. [illegible] scheme and not to the w[illegible] I should like to have the opportunity of dealing with the circular of the Medical Defence Union because in many respects I consider it to be misleading. Dr. Bateman said that the council of the Medical Defence Union was opposed to monopoly and in a letter to the *British Medical Journal* I saw a reference to American trusts and unions—the Medical [illegible] (D[illegible] BATEMAN: But not a monopoly)—t[illegible] hope, is also a union of men who help [illegible] ord association is a congeries of *soci*[illegible] proposal to extend the principle of mutual defence throughout the whole profession is, I think, a political mistake on the part of any one body carrying that work out. We mean by a monopoly, using the word in a bad sense, that a particular body of men are going to try to gather into their grasp trade in one direction and that they alone shall make a profit out of it. The use of the word monopoly in this connexion is wholly unjustifiable. What has been proposed for the British Medical Association is a union of as many members of the profession as we can possibly get together to help each other. If that be a monopoly then I am proud to be a monopolist. The council of the Medical Defence Union seems to think that the medical practitioner of this country is made for the union. When I was president of the union it was my feeling that the union was made for the practitioner and that is my attitude now. The council of the Medical Defence Union, in speaking of this matter in its general sense in its circular, said that it felt that it ought to keep the union in existence. Why? Surely it could be only in the interests of the general practitioner throughout the country; it could not be in anybody else's interests. Well, then, let us approach this subject not from the point of view of the preservation of existing machinery. Let us discuss the way in which we can extend the principles of medical defence to the largest number of the profession. I submit that it is a mistake to keep a small organisation going. There is no question of the helpfulness of competition. But surely we are not competing against each other as medical men, to defend ourselves against each other: we want to defend ourselves against the public. We can only do that by having a combination, the very combination to which, as I said before, exception was taken in the columns of the *British Medical Journal* and taken by a man who is a combinationist. The only other question that comes under consideration on the general matter, it seems to me, is this: Have the defence societies considered the subject from the point of view of the requirements of the practitioners of the country at large? I do not think that they have yet. If there is better machinery in the market surely it is best for us to put the old machinery on the scrap heap and to take the new machinery. I am looking at it from a cold-blooded point of view no doubt, but these questions are to be regarded from the cold-blooded point of view and not from that of sentiment. When we were getting the British Medical Association reorganised we were told on all hands that we were ruining the Association. What is the result? We have this year a larger balance of profit in the Association than heretofore. As regards finance, it is quite obvious that if you have got an organisation with an annual turn-over of over £40,000 that that is, *per se*, a much stronger thing than an organisation with a turn-over of £3000 or £4000. Surely that must be obvious to everyone. I would therefore suggest to you that if you want to get machinery of the greatest power the wisest thing for you to do is to take the British Medical Association and to make that your machine and to organise it for the purpose of medical defence.

After some remarks from Dr. **ALLAN**, Dr. **BIGGS** invited Dr. Hugh Woods, secretary of the London and Counties Medical Protection Society, Limited, to address the meeting; but Dr. **WOODS** said that it had been decided that his association would do nothing until the scheme was before them. Personally, he was in favour of the British Medical Association taking on medical defence.

Dr. G. A. **HERON** said:—

I have no wish to repeat Sir Victor Horsley's words but so far as this matter goes he and I think practically alike. Too much emphasis has been laid on the fact that if the British Medical Association takes up medical defence the Medical Defence Union will not give it assistance. Dr. Bateman then said that it would take years to train the British Medical Association for the work of medical defence. (Dr. BATEMAN: Quite right). Well, I venture to suggest that medical defence is very well understood even outside the ranks of the Medical Defence Union. There is another society, for instance, in existence which has not done badly in this matter, and we are quite sure that from among the branches of the British Medical Association we can get an ample supply of men perfectly competent to carry on medical defence on behalf of the British Medical Association quite as well as it is carried on now by the Medical Defence Union or by the London and Counties Medical Protection Society which although they have done such good work are really a source of weakness to each other. The most important argument in favour of medical defence being taken up by the British Medical Association is that we should have all our interests, so far as we can have it so, under one roof governed by men who are of ourselves,

up in as many [illegible]
suggested. If we medical
of the evil which has been
done to our profession by want of union, cannot come together on this subject of medical defence and show that we mean to stand by one another the sooner we give up medical defence altogether the better.

Dr. MAJOR GREENWOOD said :—

We want to be sure that in getting a medical defence society we get one which will do the best for the profession. It is possible the scheme of the British Medical Association might be better than other schemes, but we must have a reasonable
we have
de by Sir
Would it
ctitioner is
al Association? That was Dr. Bateman's point, I think. It seems to me that in such a situation you have a type of monopoly which we as a nation have always condemned. With regard to one of the defence

if we were to wind up and to join in a scheme we must at once, without any right or reason as far as dentists are concerned, say to the dentists you must go and found a medical defence association for yourselves. Again, Sir Victor Horsley spoke of a turn-over of £40 000 a year compared with one of £3000 or £4000 a year. But taking the Medical Defence Union and the London and Counties Medical Protection
d be more than £4000
tion which has to be
come coming to the
medical defence. The
y mind does not come
iple the question as to
what would be better for the profession if we could have it I agree with the motion that medical defence should be conducted by the British Medical Association.

Dr. E. A. MILLER said :—

Sir Victor Horsley referred to destroying the worst machinery, but if we do form a defence branch of the British Medical Association it is very much a question whether we shall destroy the already existing machinery. Dr. Heron has referred to the existence of two defence societies and has indicated that any advantage to one is a disadvantage to the other. His argument, brought forward in support of our forming a third association, is a most powerful argument against doing so.

After a few words from Dr. Richards pointing out that the British Medical Association had been only recently remodelled and that further development in its work had better be delayed Dr. BIGGS put the motion, when the voting was: in favour, 16; against, 7.

Dr. BIGGS having declared the motion carried called upon Sir Victor Horsley to give his opinion upon the scheme of the British Medical Association for medical defence.

Sir VICTOR HORSLEY said :—

As a former President of the Medical Defence Union I feel

the reactionary party of the Association, resolutions to alter the memorandum of association in order to carry on the individual defence of members and in order that we might extend our powers of collective defence. These resolutions have never been put into force and they are now inadequate in form on account of the reform of the constitution. The scheme which you are asked to support by the committee provides as a first item that the Association shall go forward with these proposals to alter the memorandum and to make it possible for us to defend members of

vited to merge themselves in the Association and the committee had every reason to hope that the sense of patriotism which the profession at large enjoyed would induce the existing societies to do that. Nothing, I think, has caused the members of the medical defence committee of the British Medical Association more pain than to find that that paragraph of their scheme has been overlooked. If the two societies were not willing to come

it is brought into a larger mechanism and asked to do a larger work

Years ago I endeavoured to get the subscription raised to 30*s.* I did so because I knew from a study of the balance sheet that if we had a subscription of 30*s.* the Association would have taken up the defence of all its members. It is true that the present working of defence societies shows an expenditure coming out at nearly 10*s.* per head, but I am sure in my own mind that this is an unnecessary expenditure and if in the British Medical Association we had available profits amounting to 5*s.* per head that would be enough to do the work. I think 10*s.* is an outside sum, but it would make the members of existing societies no worse off than before. If they joined our scheme their work, their interests, would be watched over by the same men for the same money. The only

Dr. E. R. FOTHERGILL said :—

complaint. We have had a
to decline. I think it is the
hould initiate no business at
us members in their various
divisions. There has been no attempt in the preparation of this scheme to consult those who have had experience. It is a one-man scheme, with all deference to the one man who is very capable.

Sir VICTOR HORSLEY said :—

The President of the Medical Defence Union was chosen as a member of the committee because of his office; the treasurer of the London and Counties Medical Protection Society was chosen because he was treasurer of that society. Finally, both secretaries were officially invited to come and help the committee.

Dr. BATEMAN said :—

Dr. Hugh Woods and myself were simply asked to attend to give evidence. We had nothing to do with the scheme.

Dr. WOODS said :—

My society was fully represented on that committee; we do not complain in any way.

Dr. Miller said:—

I have pleasure in seconding Dr. Fothergill's motion. We are anticipating if we say let the British Medical Association take up medical defence and then take in the Medical Defence Union and the Medical Protection Society. Their consent to come in should be got first.

A discussion here arose as to the accounts of the British Medical Association, the subject being considered germane to the motion because it was probable that if the Association had more money they would not find it necessary to raise the subscription.

Dr. Shaw and Mr. J. S. Whitaker having spoken,

Dr. Bateman continued in answer to Sir Victor Horsley. He said:—

I am very sorry to be in opposition to Sir Victor Horsley because I have worked with him as secretary of the Medical Defence Union and on various committees and I think I may safely say this is the first time I have ever been in opposition. The scheme is practically dead but not being yet dead one must say something about it. We have 6800 members of the union and over 1600 are not members of the British Medical Association. If we had all our members present at the meeting who are members of the British Medical Association and the 1600 who are not members of the Association turned up as well, as they have a perfect right to do, it would be absolutely impossible for us to get the necessary three quarters majority in favour of winding up, even if we wished it, And we have felt all along, and still feel, that to desert those 1600 members and also those of the union who dissent from this scheme would be a scandalous injustice to those men. It was felt necessary at once to save the time of the British Medical Association by issuing that circular. That is why the council did it. We could not call our members together but we sent a copy to every member. And with the exception of one member we have not had a dissentient from it. Therefore I think we may take it that the view of the council was also the view of the members. Those who think that the union is divided on this point I would invite to read the hundreds of letters, if they have time, in which the action of the council has been confirmed. We intend to bring this up at our annual meeting on May 26th. Any members of the union who object to it could propose a vote of want of confidence but I do not think such a vote of want of confidence would be passed.

Dr. Heron said:—

I think it is an unfortunate thing that anyone should have so misstated the fact as to say that this scheme submitted to you is the scheme of one man. It is a scheme drawn up by two members of the British Medical Association at the request of the committee appointed for the purpose of considering medical defence and these two members did their best to form a scheme which they thought might suit the circumstances of the Association as they now exist, not as they may exist in the future. That is quite another question. Because two members of the council of the Medical Defence Union who were members of the committee withdrew their consent from this scheme and published a minority scheme it is assumed that the Medical Defence Union is justified in opposing the scheme. I think this is a most deplorable and unfair attitude. The London and Counties Medical Protection Society came to the conclusion at its annual meeting that its best plan was to wait until it was officially communicated with by the British Medical Association and then to give the scheme submitted to it by the British Medical Association its best and, if possible, its favourable consideration. Surely, Sir, that is a much more charitable attitude. The reason why six members of the representative committee should be elected by the council of the British Medical Association is that the Association is going to be asked to be responsible for a considerable sum of money under this scheme and therefore it is not unreasonable. With regard to the appointment of the executive it was thought a reasonable thing that the men who would have control of the medical defence department in the British Medical Association should elect the officers with whom they would have to work and as the members of the medical defence committee would all be more or less experts in medical defence surely they would be the best judges of the sort of men they wanted to fill the various offices under them. Those who have gone into the accounts must be aware that we have got in round numbers available £6000; that is the whole surplus which we have just now. The membership of the British Medical Association is 19,000, scattered all over the British Empire—in the Antipodes, in India, in Canada. A man in the most outlandish part of the British Empire who is a member of our Association has as much right to be defended as a man in London. It is proposed that money should come out of the 25s. subscription to meet the expenses of the enormous scheme of medical defence that would be necessary. I do not see that it is possible; I do not believe you will get half a dozen sane men to undertake the management of such an affair as this with only £6000 behind them. The expenses would be enormous and I doubt whether you could work at all if you included the whole 19,000 members of the British Medical Association. You say limit it to the number of men in the United Kingdom—14 000. It costs 9s. per head to run the business of the London and Counties Medical Protection Society and 9s. to run the business of the Medical Defence Union. I differ from Sir Victor Horsley in this matter. I do not believe that, at first at all events, you will be able to bring the expenses of the British Medical Association in the matter of medical defence to a less figure than that which is now required by the two societies, which is practically the same, 9s. per head. I do not believe that you will be able to run it at less money at first though you will by-and-by. I do not see how we are to know with certainty what medical defence is going to cost the Association at the outset. So I contend that you must start with a subscription of 10s. or some other sum to set the machinery of ordinary medical defence going within the British Medical Association. Those who choose to take medical defence on those terms can get it; those who do not choose can stay out. A good deal has been said to-day about the man who is not a member of the British Medical Association. I venture to say that I have no sympathy with him; he ought to be; and if he does not choose to come into a scheme of this sort let him stay out. Also, what we have heard about a rump being formed of the existing members of the Association for defence if the British Medical Association takes this matter up. We have heard a great deal about there going to be another medical defence union. When the British Medical Association takes up medical defence and goes seriously for it the end of that rump will be no less disastrous than that of the other rump which we have read about in the seventeenth century. I hope this meeting will endorse not the details of the scheme perhaps but the principle of the scheme—namely, that medical defence should be supplied for the present in connexion with the British Medical Association until such time as the movement for medical defence is able to run alone and to pay its way.

Dr. Biggs then put the motion when seven voted for it and ten against.

Dr. Biggs then put a motion in favour of the scheme as it stood and two voted for it.

Sir Victor Horsley having suggested that a motion approving the principle of the scheme would be in order,

Dr. L. S. McManus proposed "that we adopt the principle of the scheme, thus reserving to ourselves the right to criticise its provisions." On Dr. Biggs's suggestion the words were added "and that the matter be referred to the committee of the division."

Dr. H. Evans seconded the motion and ten having voted in its favour Dr. Biggs declared it carried.

Dr. Biggs then proposed a vote of thanks to those who had come from a distance to address the meeting and this was carried by acclamation, as also was a vote of thanks to Colonel Martin for the use of the room.

ANNUAL DINNER OF THE EPIDEMIOLOGICAL SOCIETY OF LONDON.

The fifty-fourth anniversary of the foundation of this society was celebrated by an eminently successful dinner which took place at the Grand Hotel, London, on May 12th, under the chairmanship of the President, Dr. B. A. Whitelegge, C.B., chief inspector of factories. There was a numerous attendance and the guests included two very distinguished foreign representatives of sanitary administration—namely, Privy Councillor Dr. Moritz Pistor of the Ministry of the Interior of the Kingdom of Prussia and M. Henri Monod of the Ministry of the Interior of France.

After the usual loyal toasts "The House of Commons" was proposed by Mr. Balfour-Browne, K.C., and responded to by Dr. C. F. Hutchinson, M.P., who in the course of an amusing speech referred to the recently-formed medical party in the House of Commons. It was hoped that this party would form the nucleus of what in the future would prove a much larger party and that it would have before it an increasing sphere of usefulness in focussing and furthering in the House measures which concerned the public health or the welfare of the medical profession. The medical profession was but poorly represented in the House of Commons in comparison with the legal profession. The medical party would, Dr. Hutchinson felt sure, be always glad to receive the advice and assistance of such societies as the Epidemiological Society and he trusted that the society would tender such advice when it appeared to be desirable.

Sir William S. Church, Bart., President of the Royal College of Physicians of London, proposed the toast of the "Naval and Military Medical Services," and in the unavoidable absence of Sir Henry F. Norbury, K.C.B., Colonel J. Lane Notter, R.A.M.C., responded for both services.

In proposing "The Epidemiological Society" the President touched briefly upon the foundation and the development of the society and stated that of the many founders who took part in the initiation of the society in 1850 there was but one survivor, Sir John Simon, K.C.B., F.R.S. The President had at the beginning of the dinner sent to Sir John Simon a telegram of greeting from the society and he had just received a courteous acknowledgment. The society was, the President added, in an eminently flourishing condition and the last volume of the Transactions had been so highly appreciated that it was out of print almost as soon as it was published. Most of the foreign contributions which the society had recently received were due to the interest taken in its affairs by its former President, the late Professor W. H. Corfield.

Mr. Shirley F. Murphy proposed the toast of "The Visitors," with which the names of Dr. Moritz Pistor and M. Henri Monod were coupled.

Dr. Pistor, speaking in excellent English, expressed the great pleasure which it afforded him to have an opportunity of thanking the members of the society for their kindness in inviting him to deliver an address at the forthcoming meeting. The invitation arose out of his friendship with the late Professor Corfield, a friendship which he had enjoyed since the International Congress of 1891. Decades ago Englishmen appreciated the power of the axiom laid down by the late Professor E. A. Parkes that "Prevention is better than cure," and England had demonstrated to the world what the State derived from the theory and practice of sanitary science.

M. MONOD, who spoke with great fluency in English, said that he felt his honorary membership of the Epidemiological Society to be not only a personal distinction but also a tangible sign of the society's interest in the improvement of public health in France. He then gave an historical and general outline of recent legislation on the subject of public health in France. A few years ago, he said, the French had practically no laws for the preservation of health; there was no law either as to the notification of infectious diseases or prescribi [illegible] the case of such diseases or [illegible] existing law for the protection [illegible] of Feb. 15th, 1902, and came into force last year. Of course, some time must elapse before it was fully understood and generally accepted by the people, a condition which was essential to the good working of such a law. In Germany both vaccination and revaccination had been made obligatory and the French legislature, recognising that by this means small-pox could be kept in almost complete abeyance, had provided that the whole population should be vaccinated in the first year of life and revaccinated in the eleventh and twenty-first year. Proceeding to describe his own share in the preparation and enactment of these laws M. Monod said that more than 20 years ago, when he was prefect of the department of Calvados in Normandy, two of his friends persuaded him to accompany them on a visit to the First International Health Exhibition which took place in London in 1883. By what he saw there he was convinced of the social importance of public hygiene and did all that he could to encourage the movement in its favour which was beginning in France. He wrote a book to explain to his countrymen what was being done in England, he was placed at the head of the service that was created in consequence of the movement, and then had to prepare the law of which he had been speaking. At the last international congress of hygiene held in Brussels he had proposed the formation of an international public health office, the business of which would be the collection and distribution of sanitary information. That proposal was officially presented by France and by Italy to the Sanitary International Conference which met in Paris at the Ministry of Foreign Affairs at the end of last year. Nearly all the nations that were represented on that occasion signified their approval of the project and he hoped that his hearers would assist in creating a public opinion which would encourage the British Government to give its consent which had hitherto been withheld. Against cholera and plague there was only a single international convention which must govern the relations of France with all countries, whether or not they observe sound sanitary measures at home. It was impossible for the French to discriminate with regard to the shipping of different countries, but if there was such an international office or bureau of hygiene which would give all countries accurate information as to measures taken in each, then France or any other country might properly make its regulations less stringent towards progressive countries than towards those that pay little attention to public hygiene.

The toast of "The Chairman" was proposed by Dr. EDWARD C. SEATON and an appreciative reply from Dr. WHITELEGGE brought the meeting to a close.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

AN extraordinary Comitia was held on May 12th, Sir WILLIAM S. CHURCH, Bart., K.C.B., the President, being in the chair.

The PRESIDENT announced that he had appointed Sir R. Douglas Powell and Dr. A. Newsholme delegates to represent the College at the forthcoming congress of the Sanitary Institute at Glasgow; also that he had nominated Dr. H. B. Donkin and Dr. Francis Warner to act on the committee to inquire into the physical disability of recruits, in the place of Dr. G. V. Poore and Dr. J. J. Pringle who had resigned.

The following Members elected to the Fellowship at the last meeting were admitted as Fellows: Dr. Bertram Louis Abrahams, Dr. Thomas Robert Bradshaw, Dr. William Cecil Bosanquet, Dr. John Francis Harpin Broadbent, Dr. Edmund Henry Colbeck, Dr. William John Gow, Dr. Arthur John Hall, Dr. Arthur Carlyle Latham, and Dr. Charles Arthur Mercier.

A report was received from Sir Lauder Brunton, the representative of the College at the International Congress on School Hygiene at Nuremberg. The subjects discussed were of great interest and importance and the Congress itself, under the presidency of His Royal Highness Prince Ludwig Ferdinand of Bavaria, was a great success. It had been arranged that the next Congress should be held in London in the year 1907.

A report was received from the committee of management, dated May 4th, 1904, recommending that the West Ham Municipal Technical Institute should be added to the list of institutions recognised by the Examining Board in England for instruction in chemistry, physics, and practical chemistry. This was adopted.

The regulations for the first year's study and first examination of the Conjoint Board, revised by the committee of management in accordance with the reports of July 22nd, 1903, and March 22nd, 1904, of the Special Conjoint Committee, were discussed and adopted. The revised regulations apply to candidates who commence their professional study on or after June 1st, 1904.

THE ROYAL SOCIETY CONVERSAZIONE.

THE exhibits presented to view at the conversazione of the Royal Society which was held on May 13th were more uniformly interesting than usual. No particular section of science was more strikingly illustrated than another, while all branches were represented. There was no brilliant discovery to illustrate as was the case last year when Sir William Crookes demonstrated the properties of radium and, indeed, some astonishment was expressed that in view of the remarkable developments which the study of radio-active compounds has opened up only one small exhibit illustrating this property was shown.

The most striking example, perhaps, of electric phenomena was afforded by the apparatus exhibited by Dr. J. A. Fleming, F.R.S., illustrating the conduct of stationary electric waves on spiral wires. The apparatus consists of a long spiral of fine wire to one end of which is applied a very rapid electric vibration produced by the discharge of a Leyden jar. These vibrations create an electric wave which travels along the spiral at the rate of about 1500 miles per second. This wave is reflected on the far end and returns again, establishing on the helix stationary electric waves in the same way as stationary aerial waves are produced in an organ pipe. The waves are made evident by the existence of points of maximum and minimum electric force called loops and nodes which are rendered visible by the use of a series of vacuum tubes which glow when held near the loops but not if placed near the nodes. By this means it is possible to measure the length of the electric waves. The practical interest of this experiment is that applications of this kind have been utilised for measuring wave lengths in wireless telegraphy. The experiments also prove that the specific inductive capacity of glass diminishes rapidly with an increase in the frequency of the electric force. The officials of the National Physical Laboratory explained a very interesting exhibit situated in the secretary's room. It consisted of a microphone-buzzer which gives a nearly pure note of 2000 volts per second. Vibrations are started in a steel rod placed close to a polarised electro-magnet which cause ripples in the microphone current and these in turn give an alternating current in the electro-magnet which by attracting the rod maintains it in steady vibration. The exhibit included an apparatus used to investigate the distribution of temperature in the field coils of electrical machinery and an apparatus also for rapid electric thermometry. Mr. H. Jackson had a very beautiful exhibit illustrating some new phosphorescent materials. The examples shown were compounds of zinc, strontium, aluminium, and calcium which were prepared in order to show varying degrees of response to such exciting influences as violet and ultra-violet light, electric discharge, heat, and friction. It was shown that by varying the constitution of the compounds, as by increasing or diminishing their basic or acid character, the length of time during which the phosphorescent glow continues can be increased or lessened considerably. Further the property of glowing when the substance is heated can be made to persist apparently indefinitely. The effects were very beautiful. Dr. A. Scott exhibited some beautiful specimens of methyl and other related compounds of sulphur, selenium, and tellurium. The compounds served to show very clearly the close relationships of these three elements although methods employed in their preparation reveal notable differences in their behaviour with the same reagent. Considerable interest was taken in the new secondary battery designed for automobiles by Mr. Edison. In this battery the positive plate contains finely divided iron as the active material, while the negative plate has peroxide of nickel. The plates are immersed in a 20 per cent. solution of potash. A spring valve at the top is used for adding distilled water from time to time and this is the only attention required beyond electrical charging. The output is about from 13 to 14 watt hours per pound weight of cell, which is an enormous advance over the old lead accumulator. Close by Mr. Edison's exhibit Mr. Sherrard Cowper-Coles illustrated the interesting action that occurs between metals at a temperature many hundreds of degrees below their melting point. Thus iron, copper, aluminium, cobalt, and the rarer metals can be coated with zinc by placing them in zinc dust and heating them to a temperature of 200° or 300° below the melting point of zinc. The process is being used for hardening the surface of aluminium and copper alloys and for giving reflectors a hard and untarnishable surface. Professor H. B. Dixon, F.R.S., and Mr. G. W. A. Forster, B.Sc., exhibited an ingenious apparatus for determining the ignition point of gases. A vertical cylinder of Jena glass is employed, through which a current of oxygen is slowly passed upwards. The cylinder is heated electrically by a spiral of platinum wire and a thermo-couple is suspended in the cylinder, just below which is brought the orifice of a thin Jena glass tube through which the combustible gas is passed at a low pressure. The thermo-couple is gradually heated by radiation from the walls until the gas ignites. Dr. A. E. Wright exhibited his apparatus and explained the methods employed for measuring in the case of human blood its content in agglutinating substances, bactericidal substances, red blood corpuscles, albuminous substances, calcium salts, and salts generally. This exhibit excited considerable interest. Of the methods referred to some are employed, as our readers know, in connexion with the study of the changes produced in the blood when inoculated for typhoid, staphylococcic, and tuberculous infection; others are employed in connexion with the determination of the efficiency of the kidney and with the study of the conditions of blood which are associated with hæmorrhage, serous effusion, and intravascular coagulation. The apparatus employed consists in each case of ungraduated or, as the case may be, graduated capillary tubes which serve (*a*) for making progressive dilutions of the blood or of the reagent or bacterial culture which is added to the blood; and (*b*) for storing for the purpose of observation the series of mixtures of blood and reagent or blood and culture which are to be examined. The method by which progressive dilutions are made in uncalibrated tubes involves the employment of an air-bubble index. Where graduated tubes are appropriate these are graduated by the aid of an "automatic mercury pipette" or by a device involving the employment of alternate and equal volumes of water and mercury. Close by Dr. Alan B. Green exhibited some very interesting photographs illustrative of induced radio-activity of bacteria. Small masses of bacterial growth were exposed to the rays of ten milligrammes of radium bromide. In a large number of instances such masses when removed from the influence of the radium and placed between two thin sheets of inactive glass were capable of so affecting the sensitised film of a photographic plate with which they were brought into contact that on development in the ordinary way the plate showed a dark area corresponding to the shape of the bacterial mass. The photo-actinic rays proceeding from the bacteria which had been exposed to radium were capable of affecting a photographic plate through a double layer of lead foil. Professor Karl Pearson exhibited a series of photographs of English skulls illustrating normal and abnormal types from 1600 to 1850. There were two series, numbering upwards of 500 altogether, which were taken from old plague pits or graveyards in the City. The crania have been measured during the last five years at University College and the photographs are to illustrate forthcoming memoirs in *Biometrika*.

A very attractive and interesting exhibit was presented by Professor W. A. Herdman, F.R.S., illustrative of the pearl oyster fisheries of Ceylon. Samples of pearl oysters in various stages of growth were shown as were photographs and diagrams illustrating the methods employed on the pearl grounds. Specimens were also exhibited showing the structure of the pearl oyster and the position of the pearls in the body; there were shown also specimens of the cestode parasites which give rise to pearl formation and microscopic preparations illustrating the structure of the pearls. The recent investigations of the Ceylon pearl fisheries formed the subject of many beautiful illustrations by means of the electric lantern. Mr. Francis Fox exhibited some splendid stereoscopic views of the interior of the Simplon tunnel which is in course of construction through the Alps, its total length being 12¼ miles. It is interesting to point out that in this stupendous work the cutter known as the Brandt hydraulic drill is used, by means of which not only is rapid progress made but no dust is produced and thus, it is stated, miners' phthisis is avoided. The same gentleman gave a very interesting demonstration by means of the electric lantern in which photographic slides were used illustrative of the operations at the Simplon tunnel and the Victoria Falls and Gorge of the river Zambesi and the proposed bridge. Considerable interest was centred in the demonstration given by the Hon. C. A. Parsons of the auxetophone, an instrument which considerably accentuates the reproductions of the phonograph. The auxetophone is described as an air-operated valve which replaces the usual reproducing diaphragm of the phonograph. Selections of music, both vocal and instrumental, were reproduced in this apparatus and the results were very impressive.

The President, Sir William Huggins, O.M., K.C.B., D.C.L., received the guests, of whom there were a large number, including many members of the medical and legal professions and several well-known representatives of literature and art.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AN ordinary meeting of the Council was held on May 12th, Mr. JOHN TWEEDY, the President, being in the chair.

Mr. Edward Ward, professor of surgery, Yorkshire College, Leeds, was introduced and after signing the by-laws was admitted a Fellow of the College. Mr. Marmaduke Stephen Mayou was introduced and the President handed to him the Jacksonian prize for the past year together with a document declaratory of the award. Dr. Thomas Rupert Hampden Bucknall was introduced and the President handed to him the John Hunter medal in bronze and a cheque for £50, the collegial triennial prize for 1901–03, together with a document declaratory of the award.

Diplomas of Membership were issued to 98 successful candidates.

Mr. A. Pearce Gould, M.B. Lond., F.R.C.S. Eng., was re-elected, and Mr. Arthur Quarry Silcock, M.D. Lond., F.R.C.S. Eng., was elected a member of the Court of Examiners.

The President reported that as Mr. Bernard Pitts was prevented by illness from taking part in the final examination for the licence in dental surgery he had appointed Sir H. G. Howse assessor to the Board of Examiners in dental surgery during that examination.

A report was received from the committee of management recommending the institution of a diploma in tropical medicine and was referred to a committee of the Council to consider and to report.

A report was received from the finance committee stating that the arrangements had been completed for the redemption of the land tax on the premises of the College with the exception of one house let on lease.

On the recommendation of the committee it was resolved that St. Paul's Eye and Ear Hospital, Liverpool, should be added to the list of ophthalmic hospitals recognised by the Examining Board in England.

A long letter was received from Dr. Clement Dukes of Rugby, delegate from the College to the International Congress of School Hygiene which was held at Nuremberg in April last and of which several notices have appeared in our columns.[1] In his comments on the work of the Congress Dr. Dukes expressed some of his own views as follows: (1) The teachers can instruct the elder girls before they leave school in some of the duties of motherhood and the importance of breast feeding to the mother as well as to the child; (2) the elder boys and girls should be taught the virtues of purity of life and the consequences of impurity to themselves and their children, and thus aid not only in the diminution of syphilis but in the restoration of the birth-rate to its legitimate place and thus remove connubial dishonour; (3) every child at school should be influenced on the alcohol question by teaching the virtue of temperance in the adult and of total abstinence for the child; (4) the child should be taught that tuberculosis is more a house disease than an infectious disease and that it can be exterminated by fresh air in the home, however small, and in the schoolroom and by cleanly habits; and (5) the elder children in all schools should be taught the meaning of vaccination: what it has done in the past and of what it is capable. The Congress is to be held in London in 1907.

The best thanks of the Council were given to Dr. Dukes for attending the Congress as the delegate of the College.

A letter was read from Mr. F. W. Collingwood addressed to the President, forwarding statistics relating to the examinations for admission to the Navy, Army, and Indian Medical Services, showing that candidates holding the L.R.C.P. Lond. and M.R.C.S. Eng. were: (1) 22·6 per cent. more successful than candidates drawn from all other sources; (2) 28 per cent more successful than the candidates holding degrees and diplomas from Scotch and Irish universities and colleges; (3) 23·5 per cent. more successful than the Scotch and Irish graduates; (4) 15 8 cent. more successful than the Edinburgh graduates; and (5) 34·3 per cent more successful than the Dublin graduates.

The PRESIDENT stated that he had written to thank Mr. Collingwood for his letter.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8689 births and 4705 deaths were registered during the week ending May 14th The annual rate of mortality in these towns, which had been 16 0, 16·3, and 14·9 per 1000 in the three preceding weeks, rose again last week to 16·1 per 1000. In London the death-rate was 16·3 per 1000, while it averaged 16·0 per 1000 in the 75 other large towns. The lowest death-rates in these towns were 6 0 in Smethwick, 7·9 in Barrow-in-Furness, 9·6 in Hornsey, 10·2 in Willesden and in Hastings, 10·3 in East Ham, and 10·5 in Handsworth (Staffs.); while the highest rates were 19·5 in Derby, 19·8 in Coventry, 21·3 in Manchester, 22 0 in Birmingham and in Newcastle upon Tyne, 22 3 in Rotherham, 23·8 in Burnley, and 24 0 in Warrington. The 4705 deaths in these towns last week, included 525 which were referred to the principal infectious diseases, against 556, 527, and 514 in the three preceding weeks; of these 525 deaths 193 resulted from whooping-cough, 181 from measles, 58 from diphtheria, 39 from diarrhœa, 30 from scarlet fever, 18 from "fever" (principally enteric), and six from small-pox. No death from any of these diseases was registered last week in Leyton, Hastings, Southampton, Great Yarmouth, Devonport, West Bromwich, King's Norton, Grimsby, Barrow-in-Furness, or Tynemouth; among the other towns the highest [illegible] infectious diseases were re[illegible] Wallasey, Warrington, Man[illegible]on-Tees, and Rhondda. The greatest proportional mortality from measles occurred in Hornsey, West Ham, Brighton, Manchester, Huddersfield, Leeds, Hull and Rhondda; from scarlet fever in Northampton; from diphtheria in Bristol and Hanley; from whooping-cough in Hornsey, Burton-on-Trent, Handsworth (Staffs.), Birmingham, Coventry, Wallasey, Warrington, Bolton, Bury, Blackburn, Stockton-on-Tees, and Newport (Mon.). The mortality from "fever" and from diarrhœa showed no marked excess in any of the large towns. Of the six fatal cases of small-pox registered in these towns last week one each belonged to Leicester, Nottingham, Derby, Sheffield, South Shields, and Gateshead. The number of small-pox patients under treatment in the Metropolitan Asylums hospitals, which had been 123, 104, and 88 on the three preceding Saturdays, had risen again to 99 on Saturday last, May 14th; 26 new cases were admitted during the week, against 23, 12, and 14 in the three preceding weeks. The number of scarlet fever cases in these hospitals and in the London Fever Hospital at the end of the week was 1600, against 1543, 1541, and 1590 at the end of the three preceding weeks; 239 new cases were admitted during the week, against 210, 185, and 242 in the three preceding weeks. The deaths in London referred to pneumonia and diseases of the respiratory system, which had been 254, 224, and 193 in the three preceding weeks, rose again last week to 231, and were five in excess of the number, in the corresponding period of last year. The causes of 47 or 1·0 per cent., of the deaths in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Bolton, Salford, Bradford, Leeds, Cardiff, and 50 other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Liverpool, Manchester, Huddersfield, Sheffield, Rotherham, and Sunderland.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 21·0, 20·0, and 18·0 per 1000 in the three preceding weeks, further declined to 17 9 per 1000 during the week ending May 14th, but was 1·8 per 1000 in excess of the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 13 0 in Leith and 13·5 in Greenock, to 20 0 in Perth and 20·1 in Dundee. The 592 deaths in these towns included 28 which were referred to whooping-cough, 17 to measles, 15 to diarrhœa, four to scarlet fever, four to diphtheria, four to "fever," and three to small-pox. In all, 75 deaths resulted from the principal infectious diseases last week, against 79, 71, and 64 in the three preceding weeks. These 75 deaths were equal to an annual rate of 2 3 per 1000, which was 0 5 per 1000 above the mean rate last week from the same diseases in the 76 large English towns. The fatal cases of whooping-cough, which had been 29, 22, and 25 in the three preceding weeks, rose again last week to 28, of which 11 were registered in Glasgow, eight in Aberdeen, four in Dundee, and three in Edinburgh. The deaths from measles, which had been 26, 19, and 10 in the three preceding weeks, increased to 17 last week and included nine in Glasgow, four in Greenock, and two in Edinburgh. The fatal cases of diarrhœa, which had been 11, 13, and nine in the three preceding weeks, rose again last week to 15, of which nine occurred in Glasgow and three in Dundee. The deaths from scarlet fever, which had been four, three, and four in the three preceding weeks, were again four last week, and were all registered in Glasgow. The fatal cases of diphtheria, which had been seven and three in the two preceding weeks, increased last week to four, of which three were recorded in Glasgow. The deaths referred to different forms of "fever," which had been four in each of the two preceding weeks, were again four last week, and included two in Edinburgh. The three fatal cases of small-pox corresponded with the number in each of the four preceding weeks, and were all registered in Glasgow. The deaths in these towns from diseases of the respiratory organs, which had been 115, 121, and 100 in the three preceding weeks, further declined last week to 90, and were slightly below the number in the corresponding period of last year. The causes of 21, or nearly 4 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 23 3 20 8, and 23 1 per 1000 in the three preceding weeks declined again to 21·6 per 1000 during the week ending May 14th. During the past four weeks the death-rate has averaged 22 2 per

---

[1] THE LANCET, April 9th (p. 1011), 16th (pp. 1072 and 1086), and 23rd (p. 1156), 1904.

1000, the rates during the same period being 15·7 in London and 17·8 in Edinburgh. The 157 deaths of persons belonging to Dublin registered during the week under notice showed a decline of 11 from the number in the preceding week and included 17 which were referred to the principal infectious diseases, against ten, eight, and 18 in the three preceding weeks; of these, ten resulted from whooping-cough, three from "fever," two from measles, one from scarlet fever, and one from diphtheria, but not any from small-pox or diarrhœa. These 17 deaths were equal to an annual rate of 2·3 per 1000, the death-rates last week from the principal infectious diseases being 2·0 in London and 1·3 in Edinburgh. The fatal cases of whooping cough, which had been five, three, and 11 in the three preceding weeks, declined again last week to ten. The deaths from "fever," which had been one and two in the two preceding weeks, further rose last week to three. The fatal cases of measles, which had been three, two, and four in the three preceding weeks, declined again last week to two. The 157 deaths in Dublin last week included 26 of children under one year of age and 47 of persons aged 60 years and upwards; the deaths of infants showed a marked decline, while those of elderly persons were considerably in excess of the number in the preceding week. One death from violence was registered, and 53, or more than a third, of the deaths occurred in public institutions. The causes of eight, or more than 5 per cent., of the deaths registered in Dublin last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

Fleet Surgeon Standish Thomas O'Grady has been promoted to the rank of Deputy Inspector-General of Hospitals and Fleets in His Majesty's Fleet (dated Feb. 18th, 1904). Staff Surgeon Charles Marsh Beadnell has been promoted to the rank of Fleet Surgeon in His Majesty's Fleet (dated May 13th, 1904).

The undermentioned Surgeons have been promoted to the rank of Staff Surgeon in His Majesty's Fleet:—Alworth Edward Merewether, Walter Scott Harcourt Sequeira, John Charles Groscort Reed and William Elmes Mathew (dated May 13th, 1904).

Surgeon J. D. S. Milln has been appointed to Haslar Hospital.

ROYAL ARMY MEDICAL CORPS.

The undermentioned Lieutenants are confirmed in that rank:—F. C. Lambert, B. G. Patch, T. J. Wright, and A. C. Osburn.

Colonel (temporary Surgeon-General) W. F. Stevenson, C.B., is continued on the Active List as a Supernumerary to the Establishment, under the provisions of Article 473, Royal Warrant of Oct. 26th, 1900.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Lieutenant A. A. MacKeith to be Surgeon-Captain (dated April 28th, 1904). Surgeon-Captain J. M. H. Martin to be Surgeon-Major (dated May 4th, 1904).

IMPERIAL YEOMANRY.

Fifeshire and Forfarshire: Surgeon-Captain T. F. Dewar to be Surgeon-Major (dated May 14th, 1904).

VOLUNTEER CORPS.

Royal Garrison Artillery (Volunteers): 2nd Durham (Seaham): Surgeon-Lieutenant J. C. French resigns his commission (dated May 14th, 1904).

Rifle: 4th Volunteer Battalion the Royal Fusiliers (City of London Regiment): Brigade-Surgeon-Lieutenant-Colonel W. D. Waterhouse is borne as Supernumerary whilst holding the appointment of Senior Medical Officer of the 2nd London Volunteer Infantry Brigade (dated May 14th, 1904). 2nd Volunteer Battalion the Prince Albert's (Somersetshire Light Infantry): Surgeon-Lieutenant J. G. Bain to be Surgeon-Captain (dated May 14th, 1904). 5th (Perthshire Highland) Volunteer Battalion the Black Watch (Royal Highlanders): Surgeon-Lieutenant-Colonel J. Mackay resigns his commission and is granted the honorary rank of Surgeon-Colonel with permission to wear the prescribed uniform (dated May 14th, 1904).

ROYAL ARMY MEDICAL CORPS (VOLUNTEERS).

The Woolwich Companies: The resignation of Lieutenant E. B. Dowsett is cancelled. 2nd London Bearer Company: Lieutenant E. C. Montgomery-Smith to be Captain (dated May 14th, 1904).

THE WILTS AND DORSET BEARER COMPANY.

The King has approved of the Wilts and Dorset Bearer Company, R.A.M.C. (Volunteers), being formed into an independent unit.

THE WAR IN THE FAR EAST.

The manufacture of bandages is proceeding very actively in Moscow where three machines have arrived from Berlin equal to turning out 5000 bandages per day. There are 600 workers in the Red Cross workrooms in Moscow. The current of subscriptions grows in volume. At present special attention is paid to the needs of the steamer and barge hospitals.

RUSSIAN RED CROSS EXHIBITS FOR PARIS.

In the Russian section of the Paris International Exhibition, opening in the month of October next, there will be a large show of material in aid of the wounded, including a hospital tent of the Russian Red Cross Society in full working order.

THE RED CROSS IN WAR.

On Tuesday, May 17th, some interesting experiments were conducted at Bisley with inventions tending to minimise the inevitable sufferings undergone in warfare. The most striking perhaps was the First Aid Ivel motor which affords protection for two surgeons and the driver while passing through a fire zone to visit the wounded. The motor is also fitted with a large steel shield under shelter of which a bearer party can walk in safety. Another exhibit was a water cart with appliances for rapidly boiling water in large quantities, thus minimising the risks of enteric infection.

A GUIDE TO COMPANY TRAINING.

Under the title of "The Infantry Vade Mecum" Captain R. Temperley, 3rd Volunteer Battalion Northumberland Fusiliers, has reissued his compilation from official publications dealing with field training, the routine duty in camps, and other matters of interest to all ranks of infantry. The "Camp Hints" are brief but excellent though in directing that a needle and worsted should be drawn through a blister it would have been better if the author had given a word of caution against the use of dyed or soiled worsted. Non-military readers may gain many useful hints from a perusal of this little book which also throws light on the movements of troops at manœuvres, a matter of great mystery to the uninitiated. The Infantry Vade Mecum is published by Messrs. M. S. Dodds, Newcastle-on-Tyne, price 6*d.*

Correspondence.

"Audi alteram partem."

KING EDWARD'S HOSPITAL FUND FOR LONDON.

To the Editors of THE LANCET.

SIRS,—I inclose a letter from Sir John Aird generously offering to increase his annual subscription to this Fund by 100 guineas a year, this sum to be specially appropriated to the endowment in order to raise the fixed annual income of the Fund from investments and other sources to £50,000 a year. May I venture to appeal through your columns to others who may be willing to follow his example?

I am, Sirs, yours faithfully,
HUGH C. SMITH,
Chairman of the Executive Committee.

May 11th, 1904.

[INCLOSURE.]

14, Hyde Park-terrace, W.,
May 9th, 1904

DEAR MR. HUGH SMITH,—In reference to your letter about the King Edward's Hospital Fund for London in the *Times* of March 28th last, since the meeting on March 8th at Marlborough House, when His Royal Highness the Prince of Wales, President of the Fund, made the announcement that an anonymous donor was willing to give a sum —estimated to produce £4600 a year—if others would give the further necessary sum of double that amount by the end of this year in order to raise the annual income of the Fun [illegible] ts and other permanent sources to £50,000 a year, I [illegible] fund could in part be raised by annual su [illegible]

JOHN AIRD.

THE MEDICAL OFFICERS OF THE MACCLESFIELD BURIAL SOCIETY.

To the Editors of THE LANCET.

[illegible] No. 1 General Burial Society and its two medical officers who have recently resigned. This society contains 6406 members and the remuneration paid is £250 per annum for medical attendance and an [illegible] a local chemist for dis[illegible] per head per annum is a [illegible] is grossly inadequate. The payments to the medical officers are based on the proportion of sick notes received by them, each note remaining valid for the current three months. This payment is made not on the number of members entitled to medical benefit, but each medical officer is paid according to the number of sick notes received by him from the members requiring medical attendance.

In consequence of the resignation of the society's two medical officers an attempt is being made by advertisements extensively circulated in the lay press to fill the vacancy thus caused. We are most anxious that intending applicants should be made acquainted with these facts as we feel confident that no medical practitioner would accept the position which extensive experience has shown to be unremunerative and which is in direct opposition to the strongly expressed opinion of the whole medical profession in the town.

We are, Sirs, yours faithfully,

JOHN L. RUSHTON, SENR.,	ROBERT PROUDFOOT,
JAS. BRIERLEY HUGHES,	JOHN BRIERLEY HUGHES,
JOHN SOMERVILLE,	C. A. NEWBALD,
C. A. BRADLEY,	JOSEPH WESTMORLAND,
W. H. CLARKE,	J. LATHAM RUSHTON.
C. AVERILL,	L. T. FRASER,
W. H. TOWNSEND STORRS,	A. M. CLARK.
J. HEDLEY MARSH,	

Macclesfield, May 17th, 1904.

THE SO-CALLED PANCREATIC REACTION IN THE URINE.

To the Editors of THE LANCET.

SIRS,—The fact that Dr. C. E. Ham and Dr. J. B. Cleland have obtained crystals from normal urine and distilled water is in itself conclusive evidence that their technique is at fault. The source of fallacy that they apparently have not guarded against is the difference in solubility in hot and cold water of lead chloride. For while water at 0° C. only takes up 0·8 part, boiling water dissolves 4 parts. Even a few degrees difference in the temperature of the urine during neutralisation and that of the room in which it is finally left to stand will give rise to the presence of lead salt crystals such as they have met with. The undue concentration of the urine to which they refer would also facilitate the separation in crystalline form of the lead chloride held in solution by the warm urine, so that, as they remark, "the presence or absence of these crystals depends on the concentration of the liquid." Another point which has possibly contributed to their failure successfully to carry out the test is faulty filtration after neutralisation. Unless great care is taken in this process a considerable quantity of lead salts is liable to be carried through in the first part of the filtrate, especially with some samples of lead carbonate.

A little practice with pancreatic cases will demonstrate to your correspondents that the lead salt crystals they have met with are quite distinct both in behaviour and appearance from the crystals I have described in cases of pancreatic disease and that they are in no sense identical. In writing the description of the process for my Arris and Gale lecture I did not enter into these details as they are facts with which anyone having even an elementary knowledge of chemistry must be well acquainted, but I think that my directions are sufficiently explicit, provided that they are intelligently and carefully carried out.

My own experience since the publication of my lecture, and various communications I have received from other observers have only served to strengthen my conviction, that, in competent hands, the test is a useful aid to diagnosis when the results are considered in conjunction with the signs and symptoms found at the bedside, as is the case with all clinical pathological investigations. In my lecture it is distinctly stated that the theory concerning fat necrosis and glycerine excretion was only a working hypothesis on which the initial experiments were based and, whatever the doubts of Dr. Ham and Dr. Cleland may be as to its scientific basis, it has proved a useful starting point for a series of most interesting investigations.

I am, Sirs, yours faithfully,

Beaumont-street, W., May 16th, 1904. P. J. CAMMIDGE.

To the Editors of THE LANCET.

SIRS,—With reference to the letter concerning Dr. P. J. Cammidge's test in THE LANCET of May 14th, p. 1378, I should like to be permitted to mention that I have been surprised to get also positive results in cases (chiefly surgical) where no pancreatic lesion was suspected. In the last case in which the test was applied—a case of chronic bronchitis and dilated heart, with ascites—there was no indication of abnormality in the pancreas post mortem. Though limited to the experience of few cases the news that the test answers with a simple solu-[illegible]

I am, Sirs, yours faithfully,
O. C. GRUNER, M.B. Lond.

Pathological Laboratory, Leeds General Infirmary,
May 17th, 1904.

SUPPURATIVE OTITIS.

To the Editors of THE LANCET.

SIRS,—The every-day neglect of one of the most distressing diseases of childhood, suppurative otitis, is still a reproach to a scientific and humane profession. I attribute this neglect to the common impression that the disease is generally incurable—a belief engendered by numerous failures with faulty methods of treatment. There has also arisen a well-founded distrust of the radical operation so called, attended as that operation is with grave risks to life and hearing. In these circumstances I think the results already attained by my methods of intrameatal treatment are worthy of the attention of medical men. I have now performed otectomy on more than 50 occasions. This is an operation I have found useful in obstinate cases and roughly consists in the removal of remains of the membrana tympani together with other diseased tissues in the middle ear and attic. It is admittedly a bold proceeding and one to be justified by results. I will briefly summarise them. The operation has not occasioned any serious disturbance in any of my cases. The temperature remains near the normal. Only one case has complained of severe pain, while all the children operated on have seemed to be wonderfully free from pain after operation. I have had two cases of facial paralysis that soon cleared up but no case of permanent facial disfigurement. With regard to hearing, there has been distinct improvement in more than half the cases; in one still under treatment there has been so far a decided decrease in auditory power. With regard to the main result aimed at—namely, disinfection of the ear—otectomy has proved of great assistance.

I must emphasise the point that the ears operated on were in a very bad condition. Many of them had been for months under skilled treatment but they were when seen by me in a most offensive condition. The usual treatment had been thoroughly tried, in many cases by well known specialists, and had conspicuously failed. These ears are now sweet with the exception of one recently operated on and in most of them the discharge has quite ceased. A number of recent cases are now under treatment and are doing well. The conclusion I have arrived at is this, that otectomy renders possible the disinfection of a suppurating ear and gives rise to little pain or other disturbance. It opens a new and important chapter in aural surgery and I invite the attention of medical men to a method that places the treatment of otorrhœa on a more satisfactory basis.

> " Do ye hear the children weeping, oh, my brothers?
> Ere the sorrow comes with years;
> They are leaning their young heads against their mothers,
> And *that* cannot stop their tears."

I am, Sirs, yours faithfully,
F. FAULDER WHITE.

Birmingham, May 10th, 1904.

NEURO-RETINITIS IN CHLOROSIS.

To the Editors of THE LANCET.

SIRS,—In his article on Neuro-Retinitis in Chlorosis published in THE LANCET of May 14th, p. 1345, Mr. J. Jameson Evans makes me responsible for the suggestion "that thrombosis of the cavernous sinus is the primary cause of the neuro-retinitis." As no reference is given I cannot say upon what this statement is founded but I must decline to accept it as an accurate interpretation of what I have written on the subject of optic neuritis in chlorosis. It is true I have advanced various arguments in support of the view that thrombus formation in one or more of the intracranial veins or sinuses is the probable cause of this condition but I have expressly disclaimed the proposition that to produce such a result the thrombus must needs occupy the cavernous sinus. In an article published in 1902[1] I wrote: "...... It is not necessary to assume that to produce optic neuritis a thrombus must be situated so as mechanically to interfere with the venous return from the eyeballs. A thrombus once formed is for all practical purposes a tumour in the sense that it is a 'foreign body' or 'adventitious product' within the skull. And whatever conflict of opinion may yet exist regarding the manner in which cerebral tumours cause optic neuritis it is certain neither the size nor the position of the tumour is the determining factor. A thrombus in this respect doubtless behaves in the fashion set by other forms of 'tumour.'" This is an entirely different suggestion from the one with which I am credited in Mr. Evans's article and I shall be obliged if you will permit me to correct the mistake through the medium of your columns.

I am, Sirs, yours faithfully,
Harley-street, W., May 16th, 1904. C. O. HAWTHORNE.

THE OLD HARDSHIP OF LONDON MEDICAL STUDENTS.

To the Editors of THE LANCET.

SIRS,—Your annotation in THE LANCET of May 7th, p. 1293, on the Old Hardship of London Medical Students reminds me of my own case, and I shall be gratified if you will express your opinion as to whether I am justified or not in thinking myself hardly treated in these circumstances.

I am an M.R.C.S., L.R.C.P.; I qualified in 1892. I am an undergraduate of the University of London. Owing to circumstances I was unable to present myself for my final M.B., but was obliged to start practice in the country immediately I qualified. A few years ago I came here and in October, 1900, I went up for my M.B. I was referred in medicine only, not being weak in any other subject. I went up again in October, 1902, and was then referred in surgery only. I went up again in April, 1903, and was again referred in surgery only; on both these occasions I was not "weak" in the other subjects. Last October I again went up and was ploughed in midwifery only. Now I certainly do not know less of that subject than I did on the previous occasions as I had gone over the subject again, besides having had further clinical experience, and yet although on two occasions running I have thoroughly satisfied the examiners of my knowledge I am now told I am so ignorant that for that only I must be refused my degree.

You know, Sirs, the great expense and trouble that it is for a man in practice to go up for such a long examination. Surely there should be some appeal. I wrote to the medical dean and received a kind and sympathetic reply and he forwarded my letter to the registrar, but the registrar wrote saying it was very easy for a candidate to pass by a narrow margin on one occasion and to fail on the next, which was hardly *apropos*, as if I had passed by a narrow margin I should have been marked "weak." Apologising for troubling you, I am, Sirs, yours faithfully,

May 7th, 1904. HARD LINES.

THE INSTITUTE OF MEDICAL SCIENCES AND UNIVERSITY COLLEGE.

To the Editors of THE LANCET.

SIRS,—A letter from Mr. T. Bailey Saunders to the *Times* of May 19th expresses very clearly the confusion which the gift of Sir Donald Currie to University College Hospital appears to have created and to which reference was made in your columns.[1] The writer points out that he does not understand the continued existence of University College, London, after its incorporation with the University of London. He also finds in the proposed continuance of the teaching of the subjects of preliminary and intermediate medical study at University College either an apparent opposition to the essential principle of an institute of medical sciences or an indication that concentration is to take place in more than one centre, or that the institute, if created is to have its site in Gower-street. Mr. Bailey Saunders was, it will be remembered, the secretary of the commission which ultimately led to the change of the University of London to its present condition. If it is not clear to him whether it is proposed that the institute of medical Sciences should compete with what will become an integral part of the University or whether there has been a misunderstanding about the institute, and that it is merely to be a change of title that is contemplated, I think some enlightenment should be vouchsafed. It is a new and not very welcome idea that after all that has been written on this subject we may one day be greeted with the announcement of the opening in Gower-street of an "Institute of Medical Sciences, vice University College, resigned." The subject is one which needs elucidation.

I am, Sirs, yours faithfully,
F.R.C.P.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

The New Water-supply Scheme for Calcutta.—The Plague Epidemic and its Huge Mortality.—Septic Tank Installations in Bengal.

MUNICIPAL Calcutta is just now engrossed with the great scheme for an increased supply of drinking water put forward by its new engineer. According to the Act a constant service has to be installed throughout the city during the next two years but up to the present only the northern part of the town has been so supplied. It is found that the consumption under the constant supply equals about 24 gallons per head daily and the existing mains bringing the filtered water from Fulta by gravitation only supply about 20 gallons per head per day for the whole city. Already there is a cry for more water and it is stated by the native commissioners that the people of Calcutta are accustomed to use more water than the inhabitants of Europe and consequently require more. The question is how to obtain it, and the proposals put forward are (1) to construct a fresh main from Fulta, costing 21½ lakhs of rupees and giving an additional 12,000,000 gallons of water daily; or (2) to pump water into the two existing mains at 15 foot pressure so that 6,000 000 gallons extra could be obtained at an outlay of about one lakh and an annual cost of about half a lakh. The difference of expense is not so great as at first sight appears but the smaller scheme seems to find the more favour. It is a short-sighted policy and one which Calcutta will suffer for at no distant date. Apart from this increased supply the engineer proposes a scheme to obtain the necessary pressure in the distributing mains throughout the city by gravitation instead of by pumping. The proposal involves a capital outlay of no less than 33½ lakhs of rupees and consists in the construction of a steel reservoir capable of holding 5,000 000 gallons raised to a height of 85 feet at the floor. This is to be put up at the north of the town. It will be 265 feet square and 13 feet deep, covered with a galvanised iron roof, and supported by steel joists, beams, columns, and masonry. Two new trunk mains will be required as far as the centre of the city and it is calculated that a terminal head of fully 40 feet at the southern extremity of the town will be secured. The existing scheme for the constant supply will cost about 20 lakhs, but by the gravitation scheme three pumping stations in the town costing about £6000 annually will be done away with and the valuable sites can be disposed of. There can be no question that the gravitation scheme proposed is better than the one already sanctioned and the ultimate cost to the ratepayers will probably not be any greater. In a sanitary point of view the chief question is the amount of supply. It is here that the commissioners seem to have adopted a short-sighted policy. An allowance of 25 gallons per head daily must be calculated for, and as Calcutta is rapidly growing and neighbouring suburban municipalities are supplied from Calcutta also the existing mains from the waterworks will prove insufficient even with the assistance of pumping. An additional main from the waterworks at Fulta with additional filter beds and sedimentation tanks will have to be constructed. There is no question fortunately as to the quality of the water, but the position at present is that Calcutta has to face a probable expenditure of about 60 lakhs of rupees in order to secure a sufficient and well-distributed supply.

---

[1] Brit. Med. Jour., Feb. 8th.

[1] THE LANCET, March 26th, 1904, p. 880.

Plague throughout India during the past fortnight has shown a very large death roll, nearly 100,000 deaths having been recorded. The total for the past week is 46,812. The Punjab returned 26,961 deaths, as against 19,322 a fortnight ago, but this is the only increase. The United Provinces had [illegible] residency 5128, [illegible]. Central India, [illegible] ainst 1336; the [illegible]; Bombay city 706, as against 1065; Calcutta 500, as against 574; and Karachi 294, as against 293. It will be seen, therefore, that an almost general decline has commenced. Later returns show more favourable figures in both Calcutta and Bombay and in each city the outbreak has been less severe than in former years.

The Government of Bengal has appointed a committee to consider various points concerning the large number of septic tanks recently installed in the mills on the banks of the river Hoogly, more especially as to the distance from the intakes of the Calcutta and Howrah supplies at which the effluents should be permitted to be discharged without further treatment, and also upon a standard of purity for the effluents. It is desired to know the amount of work which can be done by a septic tank under different conditions, the quantities of water required, and the efficacy of the effluent as a liquid manure. The committee will report on the working of the existing tank installations in Bengal and on the means which should be adopted to render the system efficient and free from objection. The Sanitary Board for Bengal having been consulted refers to three methods for dealing with the effluent: (1) by turning it on to the land; (2) by using it as a feeder water for boilers; and (3) by drainage into the river after filtration through sand. A satisfactory solution to these questions will undoubtedly give a very great impetus to the more general adoption of the bacterial treatment of sewage in this part of India.

April 29th.

Society for the State Registration of Trained Nurses.—The annual meeting of the supporters of this society was held on May 13th at 20, Hanover-square, London, W., when Miss Louisa Stevenson presided. The annual report, a lengthy document which was read by the honorary secretary, stated that 469 applications for membership of the society from matrons and certificated nurses had been accepted during the year. It was decided that ladies and gentlemen not connected with nursing should be eligible for election as associates of the society and that the annual subscription for such associates should be 5*s*. On the motion of Mr. H. J. Tennant, M.P., seconded by Lady Helen Munro-Ferguson, a proposal approving the Bill for the Registration of Nurses introduced into the House of Commons by Dr. R. Farquharson, M.P., and urging that it is desirable, in the public interest, that a select committee should be appointed to inquire into the whole nursing question, was adopted.

THE FRENCH MUNICIPAL ELECTIONS AND THE NEW PUBLIC HEALTH ACT.

(From a Special Correspondent.)

The municipal elections held throughout France are now concluded. As usual the candidates have made loud professions of their devotion to public interests but, and this is quite contrary to the usual practice, they will on this occasion be called upon to fulfil these promises, at least in one of the most important departments of public administration. It is not the electors who will require the elected to carry out their promises. This they might have done on any or on all previous occasions, nevertheless there has been continued and gross neglect of urgent public interests. So much is this the case that the central Government has been compelled to interfere and now a new law renders obligatory what was formerly optional. To the municipalities appertains the duty of taking the necessary measures for the preservation of public health—notably in matters relating to water-supply and drainage. These and other kindred matters have been shamefully neglected or else exploited for party purposes. Instead of seeking to do what was best in the circumstances it sufficed that one party should advocate a particular scheme for the other party to attack and to denounce the scheme. Then when, after perhaps many years of wrangling, a scheme is finally adopted it may after all not be applied. The opposition may come into office before it can be realised. Then, of course, the new municipal council will not trouble itself to carry out a scheme which its members have constantly denounced as bad. Or, what is perhaps even worse, the scheme may be actually and to a large extent carried out before the council is defeated and the rival party comes into office. It is then too late for the new administration to prevent the adoption and the application of the scheme. The contracts have been signed, the works have been commenced, and there is no possibility of receding. The scheme is therefore continued, but a thousand and one petty obstacles arise because the responsible authority has no interest in the success of the undertaking. On the contrary, it has always declared that it could not be a success. This, briefly, is the history of more than one of the largest towns of France, especially in regard to general drainage and sewerage schemes. Now, however, there is legitimate ground to hope that this sort of obstruction will not continue. Much of it is due to the optional character of the schemes for sanitary reform. These might or might not be carried out, and while an element of doubt was allowed to subsist it left the door open for contentions.

To-day the new law on public health is in force. The municipal functionaries now in office are the first which have been elected since this Act has become law. Therefore we are face to face with a new departure in the history of of sanitation. Sanitary works may be rendered obligatory. The municipalities are no longer merely called upon, or invited or expected, to prepare schemes for drainage or water-supply; they can be positively ordered to see to these matters and that without any further waste of time. Article 9 of the Act says:—

> When du [illegible] f deaths in a
> commune h [illegible] the prefect
> must instr [illegible] proceed itself
> or by the [illegible] to hold an
> investigatio [illegible]

The important words in this clause are somewhat freely translated into "must instruct." The French text is: "*Le préfet est tenu de charger*"—literally, "The prefect is beholden or held to charge the departmental council," &c. Still, and however this may be, there can be no doubt as to the obligatory character of this clause. Of course but for the context this clause would not amount to anything. To investigate and to report is but too often a convenient way of shelving the whole matter. But Clause 9 goes on elaborately to explain that if the investigation shows that there is a necessity to undertake public works the prefect must call upon the commune in question to act. If the commune nevertheless does not move in the matter the departmental council of hygiene is invited to deliberate on the question and the mayor of the commune concerned is obliged to appear and to explain why nothing has been done. But there may be a conflict of opinion. The county or departmental council of hygiene may hold one opinion; the local authority, the borough or the urban district council as we should say, that is the commune, as the local unit of administration is called in France, may hold quite a different view of the situation. In that case the prefect must transmit both opinions to the Minister of the Interior who, if he thinks fit, will submit the points at issue to the Consultative Committee of Public Hygiene of France. This latter body then holds an inquiry and the conclusions of this inquiry have to be posted and rendered public to the inhabitants of the commune in question.

The experience acquired in the past has, however, fully demonstrated that with an unwilling municipality all such investigations, whether official or otherwise, all exhortations and denunciations, are of little or no use. There are elderly people, especially among the peasant class and rural populations, who cannot see why the younger generation should have better water and better drainage than they had. There are others who are more anxious to keep down taxation than to improve the sanitation of their commune and thus a majority in favour of doing nothing not infrequently governs the municipal elections. In large towns it is the rivalry of schemes combined with the rivalry of political parties which more frequently retards the application of important sanitary measures. What then is to be done when the highest technical authority in France has pronounced its opinion and nevertheless the local authorities continue to remain obdurate? The Act says that the prefect must summon the commune to proceed. If within a month of this summons the commune has not pledged itself to act accordingly or if in three months' time some steps have not been taken towards the execution of these works a decree of the President of the Republic is issued by the Council of State ordering the execution of the works and determining under what conditions they shall be done. The question of the payment is not absolutely settled by Article 9 of the Act. It states that the commune cannot be compelled to pay for the cost of the sanitary works except a law is enacted to that effect. The Council General will decide, in accordance with Article 46 of the law of August 10th, 1871, to what extent the department should share in the expenses. Indeed, a previous article of the Act foresees sanitary undertakings in which several districts may be interested and provides for their uniting to constitute a joint board for the carrying out of the works.

Article 9, it will be seen, applies especially to large drainage schemes and similar undertakings, the very sort of public works which are so often postponed for the reasons given above. As for water-supply, this is dealt with separately in Article 10 of the new law. Here the question of the necessity of such a supply and the place from which it can be obtained is complicated by the proprietary rights of the people who may be living on the gathering grounds; therefore the new law says that the decree declaring that appropriation of a water source is "of public utility" shall determine, when this is necessary, that certain lands shall be bought, and further, that a certain protected zone shall be established so as to prevent the contamination of the water. On this protected zone it shall be forbidden to utilise any human manure or to dig wells unless a special authorisation to that effect has been obtained from the prefect. The proprietors who are thus prevented from making free use of their own land will receive some compensation. Small sources of potable water which do not yield more than two litres per second may be declared "of public utility" by a simple decree of the prefect. Thus for small villages a land owner can be expropriated and a public water-supply secured without the cumbersome and expensive process of referring the whole matter to the central authorities. The compensation given is the same as in other cases where private property is taken for public purposes.

The Act also enlarges and more clearly defines the powers of the authorities in dealing with insanitary houses and areas. The mayor and municipality must issue by-laws in regard to the construction of dwellings and the sanitary services. If the commune neglects to do this, then such by-laws are to be imposed on the commune by a decree of the prefect; so we have here again the representative of the central Government armed with the necessary powers to compel the local authorities to do their duty. Further in cases of urgency, such as the outbreak of an epidemic, the prefect may order the immediate execution of such public works as are of recognised necessity. The rights to compensation and other difficulties are reserved. They will be discussed afterwards; the first thing is to get the work done and not to endanger the health of the population while lawyers quibble over technicalities. The urgency which justifies such summary proceedings must be declared and recognised by a decree issued by the mayor and, in default of the mayor, by the prefect. Here, again, we have a useful proviso, for it often happens that a mayor would not care to vex, and perhaps to injure, the business prospects of his electors by publicly declaring that an epidemic had broken out in the town or the locality. This is especially the case in holiday and health resorts. The local interest then clashes with the general and national interest and therefore it is necessary that the prefect, who represents the wider interest, should have the power to counteract any manifestation of selfishness displayed by the representatives of local interest. Again, and without going to such lengths as this, it is very useful for the elected local authorities to be able to explain to their recalcitrant and unappreciative electors that in undertaking sanitary works they were forced to act and that the prefect would interfere if they attempted to postpone the public works which the health authorities had declared to be necessary.

The intervention of the prefect is sanctioned when the local authorities wilfully fail to accomplish their duty or else in cases of urgency. It is, however, not easy to define what constitutes urgency. In a Ministerial circular to the prefects explaining this law the opinion of Professor Cornil is quoted. Writing on behalf of the Consultative Committee of Public Hygiene of France Professor Cornil says that urgency arises "when an epidemic of unusual gravity breaks out, when there is some imminent danger to public health; when, as occurs in certain cases, the powers of the mayor do not suffice to cope with the gravity of the situation; when it is necessary to take at once certain measures which, according to the ordinary procedure, would entail formalities occasioning a long delay." The Ministerial circular very wisely explains that it is not necessary to wait till the danger is widespread. The gravity of the potentialities must be considered; the facility with which the disease in question may extend constitutes the danger and it is not necessary to wait till it has spread to take the precautionary and sanitary measures.

Thus it will be seen that the new Public Health Act of France gives the representatives of the central Government—that is to say, the prefects—the power to compel the local authorities to take necessary sanitary measures. Apart from many other matters of less difficulty, at least from the financial point of view, such as the notification of infectious diseases, vaccination, disinfection, the control of lodging-houses, &c., the Act, it will be seen, deals with the three most expensive problems. These are: first, general schemes of drainage; secondly, water supply; and thirdly, insanitary areas, slum property, and unwholesome dwellings. All these three questions involve a large outlay and interference with private property. Therefore they invariably occasion much contention and bring about a great clash of interests. It requires a strong hand to deal with such conflicting elements and very often the local authorities, who are elected by the very persons whose private interests are at stake, do not possess this indispensable determination and strength. Therefore the occasional intervention of the prefect should prove of great advantage. The prefect at least should be absolutely immune from the effects of local pressure His appointment depends on the Minister and not on the local voters. On the other hand the local voter has just exercised once again his right to vote. Will the new municipal councils, strengthened by the new Public Health Act and stirred on by the prefects who now possess greater powers to interfere, be able to proceed more rapidly than in the past? The delays and postponements which have occurred constitute a national scandal, notably in such towns as Toulon and Havre, where the permanent presence of typhoid fever and the virulence of the cholera epidemics have failed to act as a warning. For years the necessity of a general drainage scheme for these towns has been discussed but no such scheme has been carried out Thousands of lives would certainly have been saved if proper sewers had been laid in the streets and the houses had been suitably drained. Scheme after scheme has been brought forward and fought over by the rival parties and now they rest in their respective pigeon-holes The abominations prevailing during the cholera epidemics subsist to-day. It is to be hoped that the new law and the new municipalities will at last put an end to so disastrous a state of affairs.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

Reply of the University to Antivivisectionists.

SOME time ago a memorial was sent to the council of the University by a number of persons—of whom I understand the majority were non-resident in Birmingham or even in the Midlands—asking that if vivisection were to be practised in the University permission should be withheld for experiments requiring a certificate exempting partially or entirely from the use of anæsthetics. To this memorial a reply has now been sent by Alderman Beale, the Vice-Chancellor of the University, in which he states that the council of the University recognises the anxiety of the memorialists for the welfare and humane treatment of animals, a feeling cordially shared by every member of both council and senate. They would point out that the certificate permitting a test to be made without an anæsthetic is intended for inoculation or feeding experiments, where the administration of an anæsthetic is wholly superfluous or impossible, and in any case would subject the animal to much more discomfort than the trivial puncture or scratch itself. The certificate is not used for other experiments. With the exception of these inoculation and feeding experiments, permission to retain the animal alive after an operation is rarely asked for and is only permitted when a granted for a particular experime is issued the operator must sati object of the research is important and that there is a sufficient prospect that valuable information may result from it. The medical faculty has reported that so far no such special certificate has been applied for, nor will any be applied for unless the Faculty itself has come to the conclusion that in the particular case the object in view is of great importance. The council accepts this assurance and having received a report upon the whole matter from the senate is of opinion that it is not necessary to impose any other conditions than the very stringent regulations laid down in the Act of Parliament and most fully carried out.

University Appointments, &c.

Dr. P. H. Pye-Smith, F.R.S., Vice-Chancellor of the University of London, has consented to deliver the address at the opening meeting of the faculty of medicine which will take place on the evening of Oct. 3rd. Dr. W. A. Potts has been appointed assistant lecturer in pharmacology, and Dr. R. M. Simon examiner for the Russell memorial prize for this year. The first Ingleby lecture for this year was delivered last week by Dr. O. J. Cullingworth. The lecturer devoted the first portion of his discourse to an account of the life of Dr. Clement Ingleby, in whose memory the lectureship and two scholarships were founded, after which he turned to the subject proper of his two lectures—viz., a plea for early exploration of the abdomen in suspected cases of cancer of the ovary.

Health of Birmingham: Fresh Case of Small-pox.

When the last patient was discharged from the small pox hospital on March 31st it was hoped that the city might remain free from that trouble for some time to come. At the same time it was pointed out that with Leicester and other foci of disease in the neighbourhood, and with the coming in of warmer weather leading to a greater circulation of the tramp population along the roads, it was highly probable that further cases might occur. As a matter of fact one has occurred, for a week ago a case was discovered in the person of a man who had been residing for some time previously at South Shields but had come to Birmingham to work about a week before his illness became obvious. As soon as his condition was diagnosed he was removed to the small-pox hospital and all the persons with whom he had been in contact were placed under observation. The city has lately been suffering from an unusually severe epidemic of whooping-cough and that disease is still very prevalent, the numbers of deaths registered from it in two recent weeks having been 34 and 21 respectively. There are about 200 scarlet fever patients in hospital.

Ear and Throat Hospital.

The fifty-ninth annual meeting of the supporters of this charity has recently been held under the presidency of Alderman J. H. Lloyd. The annual report stated that the total ordinary income of the hospital for the year amounted to £2225 and the ordinary expenditure to £2323, leaving an adverse balance of £98, notwithstanding that the in-patient department was closed for several months whilst building operations were in progress. The number of in-patients treated during the eight months that the wards were open was 781, as compared with 1191 during the previous 12 months, the daily average being 23, as compared with 24 in the previous year. The number of out-patients was 7872, as against 8122. Of the in patients 25 were admitted free, eight very urgent cases obtained some tickets after their admission, and 95 other cases were also treated, although unable to obtain the full number of tickets. The cases admitted from places beyond Birmingham and the suburbs were 281 in number, or 35 9 per cent., being 114 less than last year. Of the new out-patients 1295 cases were admitted from places beyond Birmingham and its suburbs, being 27 2 per cent., and 100 less than last year. The committee reported with regret that the donations to the hospital extension fund amounted only to £2015 towards the £6000 asked for, and to meet in part this deficiency the committee authorised the trustees to realise the corporation of Birmingham gas and water annuities. The hospital bank account was now overdrawn to the extent of £2198 and the committee begged for donations to enable it to reduce the amount and so to save the heavy charges and the interest thereon. The alterations and extensions were now complete and had fully realised the expectations of the committee in enabling the work of the hospital to be carried on in a more efficient manner.

Hanley Health Report for 1903.

Mr John Clare, medical officer of health, in his report for 1903 states that the area of the borough is 1768 acres and the population 63,166. The birth rate for the year was 34 8 per 1000, as compared with 35 1 for the previous year. The death rate was 16 4 but if the deaths of inhabitants of the borough in the workhouse, isolation hospital, and North Staffordshire Infirmary were included the death-rate was 19 per 1000. With the exception of December the death-rate was very low, but even including that month it was still below the average of the past ten years—viz, 19 6 per 1000. The zymotic death-rate was 2 3, or, including deaths in the isolation hospital, 3 per 1000. The deaths of children under one year of age to 1000 births were 170. This heavy infantile mortality is greatly to be deplored but so long as mothers work in the different manufactories instead of looking after their young infants there will be little amendment in this direction. The outbreak of small-pox which took place in the autumn of 1902 continued throughout 1903 up to October when the last case was notified. The cases that occurred up to July were dealt with by "quarantining" them but this plan was then abandoned as being extremely expensive and of very little use, besides entailing a large amount of harassing and arduous work on the sanitary officials. An empty house belonging to the corporation was fitted up where the inmates of infected households could be moved while their houses and clothes were being disinfected. They were then revaccinated and allowed to follow their employment, a close watch being kept on all who had been in contact with small-pox. No case occurred amongst them as it was found possible to revaccinate them all. A great deal of revaccination was done but Mr. Olare found it very difficult to impress upon the adult portion of the community the danger that they ran, the effects of primary vaccination having in a very great measure passed away. A lesson teaching how expensive and dangerous were vagrants to the community had been afforded and it was desirable that some steps should be taken to prevent them spreading disease. Amongst them revaccination should be compulsory. 472 cases of diphtheria were recorded. The principal causes of the spread of this disease were the contact of children in the schools and the neighbours visiting infected houses. There were 44 deaths in the borough and 32 in the hospital from it.

May 16th.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

The Milk Standard.

AT the Oldham police-court on May 12th a case occurred which illustrates the difficulty of fixing a satisfactory milk standard. The difficulty is caused in great part by cows declining to give milk of uniform quality. The magistrate's clerk said that in this case the difference between the standard and the analysis return was very small. "Farmers had protested against the order because the quality of milk varied so much according to the feeding, the weather, or whether the cow was in good, bad, or indifferent health." The milk from two cows in equally good health and condition, with the same feeding and surroundings, may also differ considerably in quality and that constantly. The defendant said the milk had deteriorated because he had been unable to buy food and he had given up selling milk—not apparently any too soon In these circumstances the case was withdrawn. It almost seems as if the small cow-keeper will be unable to maintain his position.

"*Herbal Treatment.*"

An inquest was held about ten days ago at Moston, a suburb of Manchester, which shows the strong hold that irregular treatment has on the minds of a certain class of Lancashire people. In this case, however, there was in addition neglect amounting to cruelty. A girl, aged 15 years, a worker in a mill, had been ailing for eight months. She had unfortunately a stepmother who was often advised by a neighbour to call in a medical man, but she was met with the reply that the girl was lazy and her illness a pretence. No medical man was called in and the girl died. Now comes the characteristic feature of the case. The father told the coroner that he did not send for a medical man as he thought his daughter was only suffering from indigestion. It seems that, like many of these people, he had an old book, "a medicine-book which he had bought 20 years ago." He said it had been his custom to treat ailments from prescriptions in this book and he gave his daughter "a decoction of herbs" for six weeks. "He did not know what the properties of the herbs were." Dr. McLean stated in evidence that the girl had been badly nourished and had died from peritonitis, that she must have been in great pain for months, and that proper medical treatment, though it might not have saved her life, would have prolonged it and would have alleviated her sufferings. The coroner spoke strongly of the conduct of the father and stepmother and the jury, who returned a verdict of death from natural causes, asked that they should be censured. It is difficult in such cases as these (which are far too frequent, not so much among the very poor as among those a little above them in the social scale, who may have had all the advantages of a board school education) to know how the various factors that cause such pitiful suffering are proportioned. Ignorant self-conceit, penurious dislike to paying even the smallest fees, suspicion, evidently strong in the stepmother, that this poor girl was malingering, and credulous trust in the prescriptions of the old medicine-book all had a share. The only satisfactory point in this case is that a Lancashire jury of the same class as the father and the stepmother agreed that they deserved censure.

River Purification.

At the last monthly meeting of the Mersey and Irwell Joint Committee an estimate of the expenditure for the year ending March 31st, 1905, was presented. The total is a net sum of £4524, which will be raised by calls upon the local authorities.

Moss Side to be Prosecuted.

At the same meeting Moss Side, a suburb which may be said to be in Manchester, though not of it, came under animadversion and legal proceedings are to be taken against the urban council. For the chief inspector found on a visit on April 19th about one-third of the whole volume of tank effluent passing directly to the Mersey through a hole cut in the ground communicating with the drains underneath. This hole was filled with paving stones, which, of course, provided a very effective way of not treating the sewage.

Sir Henry Roscoe's Report.

In Sir Henry Roscoe's report on the sewage effluents from the works of local authorities it is stated that of 41 samples 22 were good, eight were fair, two were unsatisfactory, and nine were bad. The Bolton corporation was to be informed that the effluent from its Rhodes farm was unsatisfactory. The purification of our rivers is a terribly slow process and we are paying heavily in money as well as in other ways for our own carelessness and for the neglect of our predecessors.

Mid-Cheshire Hospital Scheme.

The Cheshire county council has applied for the sanction of the Local Government Board to borrow £14,500 for the erection of an infectious diseases hospital to serve the districts of the Northwich rural and the Northwich, Winsford, and Middlewich urban councils. The district has a population of 54,735 and the hospital will accommodate 16 scarlet fever and ten typhoid fever patients. Eight other beds will be provided in an observation block. There will also be accommodation for a staff of 15 persons. The total cost is "estimated" at £14,235.

Ophthalmia in a Derbyshire Village.

The village of Staveley in Derbyshire is reported to be suffering from an epidemic of acute ophthalmia. The county medical officer reports that fully 200 children and their parents have been attacked within the past two months. The rural authorities have given notice that "unless medical attention be immediately sought by those affected a loss of eyesight will surely result."

May 17th.

WALES AND WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENTS.)

Bridgend Workhouse.

AN extension of the Bridgend workhouse has been frequently urged upon the board of guardians during the past ten years, not only by the medical officer (Mr. Wyndham Randall) but also by the Poor-law inspector of the Local Government Board. The latter official reported to the guardians in 1902 that on going through the house on one occasion he had found in the sick wards 38 patients in 31 beds and that there were no women's receiving ward, no suitable lying-in ward, and no proper vagrant wards. As recently as March last it was reported that there were not enough beds to accommodate all the inmates, so that one man had to sit up all night and another slept on a bench, and it was suggested that beds should be put up in the dining rooms. Plans for the provision of a new infirmary, casual wards, a porter's lodge, and other minor buildings were prepared some time ago and have been approved by the Local Government Board, but on several occasions the guardians have refused to carry out the work although the total estimated cost of £13,500 would only involve an annual expenditure for 30 years of a rate equal to ½*d*. in the pound. The opposition to the scheme has at length been overcome and on May 14th it was decided by 42 votes to 20 to apply to the Local Government Board for sanction to borrow the sum named.

Proposed Reduction of the Salary of a Medical Officer of Health.

Allusion was made in THE LANCET of Jan. 23rd, p. 261, to the extraordinary proposal of the Aberavon town council to reduce the salary of the medical officer of health (Dr. J. Arnallt Jones) by including in the amount—£50 per annum—all fees to which he is entitled under the Infectious Disease (Notification) Acts. The assumption that the Local Government Board would not consent to this proposal has been borne out and it is to be hoped that the Board will not sanction the alternative proposal of the council to appoint a medical officer of health at the reduced salary of £25 per annum. Some years ago the sanitary committee of the Cornwall county council recommended that the minimum yearly remuneration of district medical officers of health in the county should be upon this basis—a preliminary fee of £10 for each district, with an additional £5 for every 1000 of population and an additional £2 for each 10,000 acres after the first 10,000. The population of Aberavon is about 8,000 and the area is 2211 acres, so that upon the Cornwall basis the minimum salary should be £50 per annum.

Cardiff Seamen's Hospital.

The new building which is to take the place of the hulk *Hamadryad* is now completed and only requires furnishing to be ready for occupation. There is accommodation for 60 patients. Of the £30,000 which the building has cost the late Marquis of Bute gave £20,000. A portion of this sum was given during his lifetime and the remainder was bequeathed. His trustees were directed upon the completion of the hospital to arrange that the sick received in the hospital should be served by sisters of some Roman Catholic religious order if such arrangements could be made. The question of giving effect to this clause in the will of the late marquis has been before the hospital committee more than once. In June of last year the trustees were informed that provision would be made for Roman Catholic patients having nurses of their own faith and Roman Catholic priests would be given the same free access to patients in the new hospital as they are now given in the *Hamadryad* hospital ship. The trustees do not appear to consider that this would sufficiently carry out the wishes of the testator which they believe were that the indoor administration of the hospital should be intrusted to some Roman Catholic sisterhood competent to provide duly qualified nurses. When this view was placed before the committee on May 12th it was pointed out that the general public had subscribed to the building fund of the hospital on the understanding that it was to be administered on unsectarian lines and one member of the committee said that they might just as well close the wards as place them exclusively in charge of Roman Catholic nurses. Ultimately three members of the committee were deputed to confer with the trustees and it is confidently believed that a solution of the difficulty will be arrived at.

Medical and Surgical Degrees for the University of Wales.

It is proposed by the court of the University of Wales to apply for a supplemental charter for the creation of affiliated colleges. This is the outcome of an appeal from the Swansea Technical College to have the right to present candidates for degrees at the University. At the court held at Holyhead on May 13th Sir Isambard Owen, the senior deputy chancellor, moved that there should be contained in the supplemental charter power to grant degrees in medicine and surgery. In a communication supporting this suggestion Sir John Williams said it was not fair to students that they should be obliged to go elsewhere for a degree in medicine nor was it fair to the University, for it is deprived of the credit which would accrue to it from a distinguished roll of medical graduates. The proposal was unanimously adopted by the court.

The Prevention of Tuberculosis.

The annual meeting of the Gloucester, Somerset, and Wilts branch of the National Association for the Prevention of Consumption and other Forms of Tuberculosis was held at the Council House, Bristol, on May 13th under the presidency of Sir John Dickson Poynder, M.P. The chairman stated that the funds at their disposal had permitted the executive committee to extend operations in connexion with the Winsley Sanatorium. The original block of the building was practically completed and the second block which would enable them to take the full number of 60 patients was well in hand. Dr. L. A. Weatherly (chairman of the executive committee) said that £16,660 had been already received for the building and £2275 per annum for the maintenance fund. £6256 had still to be collected. The Bristol city council has now the right of nomination for 20 beds, having recently increased its subscription. All the beds of the sanatorium with the exception of five are now allotted to public bodies or private individuals. The institution will not be opened for the admission of patients until the end of November when the whole building will be completed.

May 16th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Glasgow and District Branch of the National Association for the Prevention of Consumption and other Forms of Tuberculosis.

THE third annual meeting of this branch was held on May 12th in the Religious Institution rooms, Glasgow, when the Hon. the Lord Provost (Sir John Ure Primrose) presided. The council submitted the annual report on the procedure adopted for the year preceding March 31st last, in which it was stated that there have been a gradual and decided extension and development of the various methods by which the prevention, suppression, and treatment of consumption in the city and district can be successfully attained. The council reported especially on the distribution of pamphlets and literature and the holding of public meetings in the various districts of the city as a means of educating the public on the subject. With the view of arousing the interest of the members of the various benefit and friendly societies in the city and district in the proposed sanatorium at Lanark Dr. Alfred P. Hillier, secretary of the National Association, London, at the request of the council delivered an address at the annual public meeting held in November last on the Advantages of Sanatorium Treatment to Benefit and Friendly Societies. The lecturer dwelt on the position of friendly and benefit societies in Germany towards sanatoriums and discussed how far these societies in Great Britain might advantageously follow their example. The council was well satisfied with the success of that meeting. In connexion with the treatment of advanced cases the council regrets that meantime it is quite unable to undertake this part of the work. It has, however, been in conference with the subcommittee of the town council on tuberculosis and has suggested that the latter body might experimentally, at least, provide some hospital accommodation for such cases. This matter is still under consideration. With regard to sanatorium treatment, it was stated that plans had been adopted and approved by the county council for the erection of a pavilion and five double sleeping chalets. These are now in course of erection at Bellefield, Lanark, by Messrs. Speirs and Co., contractors, and will provide accommodation for 30 male patients as early, it is hoped, as June. It is expected that additional accommodation will be provided at no very distant date. Special reference was made to the valuable aid rendered by the editor and staff of the *Glasgow Evening News* in establishing and working up the "People's Fund," now exceeding £7400, also to the handsome donation of £5000 by the corporation of Glasgow towards the erection of the sanatorium. Graceful reference was also made to the practical interest taken by Lady Ure Primrose who two days before had invited and entertained to afternoon tea in the Royal Institute of Fine Arts those interested in the movement with the view of considering what part should be taken by the ladies of the city in the crusade against consumption. The council records with regret the death during the past year of Sir John Muir, Bart., and Mr. William Quarrier, two of the honorary vice-presidents of the branch. By the death of Mr. Quarrier, who was the pioneer in the adoption of sanatorium treatment for consumptives in Scotland, the branch has lost much valuable help.

Opening of Lanfine Home for Consumptives at Broomhill, Glasgow.

On May 14th the Duchess of Montrose opened the Lanfine Home for Consumptives. Sir James King, Bart., who opened the proceedings, said the new Home for Consumptives was an institution built by the generous bequest of an Ayrshire lady, Miss Martha Brown. It was noteworthy that this gift was the indirect result of the influence and advice of a lady whose name would ever be honoured at Broomhill, Miss Beatrice Clugston, who some 25 years ago had interested Miss Brown in the Broomhill Home. Together with Miss Clugston Miss Brown had formulated a scheme much like that now being carried out and at her death left to the institution the sum of £21,000 Of that sum £1000 went to aid outside pensioners, £5000 to erect the consumptive home, and the remaining £15 000 towards its annual endowment. The annual interest on the money left would be quite insufficient to provide for the maintenance of the new institution, for there would be a deficit of £500 per annum. As the ordinary revenue of Broomhill was during the past year £700 short of the expenditure it followed that £1200 more per annum would be required. Her Grace the Duchess of Montrose in formally declaring the home open, said she considered it an honour and a privilege to be in some way associated with such an institution as the Lanfine Home. Miss Clugston was the source of inspiration for the home and with Miss Brown had conferred permanent benefits on humanity.

Aberdeen Royal Infirmary: Limited Accommodation for Patients.

The directors have issued the following circular to medical practitioners, public officials, and others, drawing attention to the limited accommodation at the hospital: "Owing to the limited accommodation in the infirmary (especially in the surgical side), the board of directors hereby intimate to all medical practitioners and others that before sending patients to the hospital it is necessary to communicate with the medical superintendent of the infirmary, with the view of ascertaining if accommodation be available. At the same time there should be forwarded a short statement as to the nature and urgency of each case for information. If the services of any particular physician or surgeon are desired this should be mentioned in the application, when every endeavour will be made to meet the wishes of the applicant. Intimation of the date at which the patient can be admitted will be forwarded as soon as possible after the application has been received. Cases of accident are admitted at once."

Appointments.

Dr. John Innes has been unanimously recommended by the cleansing committee of the Aberdeen town council as medical officer to the cleansing and carting staff of the corporation.—Dr. J. Reid of Portsoy has been appointed in succession to Dr. W. L. Stewart certifying surgeon under the Factory and Workshop Act for the district of Portsoy, which includes Portsoy burgh and the civil parish of Fordyce.

Inverness Northern Infirmary: Annual Meeting.

The annual meeting of the managers of the Northern Infirmary was held in the council chamber, Inverness, on May 4th. Provost Arthur D. Ross presided and there was a good attendance. Mr. Duncan Shaw, W.S., honorary secretary, submitted the annual report of the house committee, and Mr. C. Marshall Brown, honorary treasurer, read the annual financial statement. The report of the house committee stated that the number of patients during the past year was about the average. Two outbreaks of scarlet fever, which became epidemic, had largely increased the number of patients in the fever wards. The number of patients at the first outbreak was as many as 47 and at the second outbreak they numbered 97. Great credit was due to the officials for the arrangements which made it possible to treat such a large number of patients. The financial statement showed that the ordinary income for the year amounted to £3986 13*s* 3*d*. and the expenditure to £5356 13*s*. 1*d*., leaving a deficiency of £1369 19*s*. 10*d*., which had been met by applying legacies received during the year amounting to £809 19*s*. 7*d*. and the withdrawing of £560 from capital account. There was a further withdrawal of £439 to meet expenditure, the net result of the withdrawals being that the accumulated funds of the institution had been reduced by £1000 during the year. A strong appeal was made for increased public support in aid of the institution which was doing such valuable work. Provost Ross moved the adoption of the reports. He referred to the fact that out of 130 cases in the scarlet fever epidemic not a single death directly resulted from the fever. He mentioned that the cost per patient in the infirmary during the year was less than for some years past and this showed that economy was being used in the management of the work of the infirmary. In conclusion Provost Ross moved the reappointment of Mr. Duncan Shaw as honorary secretary and of Mr C. Marshall Brown as honorary treasurer and that a vote of thanks should be given to them for their services during the past year. Ex-Provost Macbean seconded the motion which was cordially adopted.

May 17th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

National Children's Hospital, Dublin.

THE annual meeting of the supporters of the National Children's Hospital, Dublin, was held on May 13th in the hospital premises, Harcourt-street. Sir Charles Cameron, C B., presided and there was a large attendance. Sir Lambert H. Ormsby, President of the Royal College of Surgeons in Ireland and surgeon to the institution, said that the three great objects of the hospital were: (1) the medical and surgical treatment of sick children, (2) the diffusion of knowledge among students regarding diseases of children, and (3) the training of nurses in the diseases peculiar to children.

The late Patrick Joseph Hayes, M.D. R.U.I., F.R.C.S. Edin.

The lamented death of Dr. P. J. Hayes took place on May 11th at Idrone-terrace, Blackrock. He filled for a quarter of a century the position of surgeon to the Mater Misericordiæ Hospital, Dublin, was widely known, and was in the enjoyment of a large practice. He was a Medical Fellow of the Royal University which conferred on him the degree of doctor of medicine *hon. causâ* and ever since the establishment of that University he had been one of its examiners in surgery. Dr. Hayes was consulting surgeon to St. Patrick's College, Maynooth, and to several other important institutions in Ireland. For many years he was well known as professor of surgery to the Catholic University and his memory will be long cherished by hundreds of medical men now scattered over Ireland, England, and the colonies. Some two years ago when his health began to fail he retired from practice and changed his residence from 18, Merrion square to Blackrock. He has left a widow and family to mourn their loss.

County Tipperary Lunatic Asylum.

At a meeting of the committee of the County Tipperary Asylum, held at Clonmel on May 10th, the salaries of Mr. B. G. Harvey and his assistant, Dr. P. Heffernan, were voluntarily increased by £100 and £50 respectively as a recognition of their efficient work by which the cost of maintenance of the institution had been reduced by about £2000 a year.

Rainfall in April.

In the month of April in the north of Ireland the rainfall was 3 20 inches, rain falling on 29 days, an amount distinctly above the average (2·51 inches). The total amount of rainfall for this year is, so far, 12·76 inches, which is over the average (11 72 inches).

Medical Benevolent Fund Society.

At the annual meeting of the Belfast and County Antrim branch of this society held in the Medical Institute, Belfast, on May 13th, it was reported that a sum of £147 8*s*. 11*d*. had been remitted to the central authority in Dublin, being £12 13*s*. 6*d*. less than the previous year. A larger number of country subscribers are on the roll this year but in Belfast there are 15 subscribers fewer and the amount is less by £6 5*s* 6*d*. than that of last year. Marked attention was drawn by the various speakers to the want of success of the society in Belfast where, it was said, 45 members of the profession do not subscribe. A vote of thanks was passed to the retiring President (Sir W. Whitla) for his services to the society and Dr. J. Nelson was appointed President.

Small-pox in Limavady Union.

The small-pox patients are all doing favourably and there are no fresh cases, a circumstance attributed by Dr. J. W. Watson, the medical officer of the workhouse, to the effect of revaccination. The guardians of Limavady have decided as an alternative to receiving into the workhouse destitute members of families of those bread-winners who had been or might be removed to the hospital as small-pox patients that these families should be given such temporary relief in their own homes as might be suited to the requirements of each case.

May 17th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Surgical Treatment of a Wound of the Heart.

AT the meeting of the Society of Surgery which was held on April 27th M. Richet read an account of an operation performed for wound of the heart. The left ventricle had been perforated by a revolver bullet eight millimetres in diameter which had also grazed the greater curvature of the stomach, the upper border of the spleen, and the lower border of the left lung. The patient, a man, aged 34 years, was taken into hospital 15 minutes after the accident. He was at once given injections of caffeine and of artificial serum and the operation was begun in one and a half hours after the accident. The wound of entrance was in the fifth interspace and there was pneumothorax. A large flap was made from the whole thickness of the thoracic wall and the two wounds in the heart and those in the pericardium had been sutured with catgut, when the heart ceased to beat despite direct massage of the organ being employed M. Richet reminded the meeting that his first similar case had been successful and that he had shown the patient before the society in perfect health.

The Treatment of Urinary Incontinence by Lumbar Puncture.

At the meeting of the Hospitals Medical Society held on April 29th M. Babinski and M. Boisseau showed two patients who had suffered from incontinence of urine and had been cured by lumbar puncture. The first patient was a young woman, aged 17 years, who ever since the age of seven years had suffered from nocturnal incontinence. Lumbar puncture was performed and 15 cubic centimetres of cerebro-spinal fluid were drawn off, the patient having no incontinence for the eight following days. From the ninth to the thirteenth day she had incontinence twice. A second puncture was then made and on the fifth and seventh day after this operation the patient had incontinence, but since that date, two months ago, she had had none. The second patient was syphilitic and for two years had suffered from spasmodic paraplegia and incontinence both of fæces and urine. The incontinence was not due to overfilling of the viscera but to paralysis of the sphincters. Lumbar puncture was performed and 15 cubic centimetres of fluid were withdrawn and the incontinence disappeared. The patient could pass the water voluntarily and felt both the need of passing water and the passage of the urine, which had never been the case previously. M. Babinski and M. Boisseau had seen two other cases of the same kind. The one was a child, 14 years old, who had suffered from incontinence both by night and day for six weeks. Belladonna had been tried without result but after lumbar puncture the diurnal incontinence disappeared altogether, but the nocturnal incontinence reappeared two months after the operation for one month, but only every four nights or so, and finally disappeared altogether 15 days after lumbar puncture had been performed for the second time. The other patient had suffered from paraplegia for a year and had had nocturnal incontinence for one month. After one lumbar puncture this incontinence disappeared and had not reappeared for a fortnight. Finally, a patient suffering from ataxia who had had incontinence for four years received no benefit from lumbar puncture, although three years previously the incontinence had ceased for 15 days after a lumbar puncture made for the purpose of a cytological examination. Without pretending to explain the mode of action of this treatment M. Babinski and M. Boisseau considered that it was a good method of treatment for a very troublesome affection and that it was quite worth while to make further researches into the matter.

May 17th.

Obituary.

M. DUCLAUX

OUR Paris Correspondent writes:—"I have already announced to your readers the news of the death of M. Duclaux but it is only fitting that they should receive some further information as to the career of one whose name is universally known. The late director of the Pasteur Institute was a brilliant journalist as well as a professor and a notable fighter as well as a laboratory worker. All his life he was an indefatigable worker He began as a mathematician in 1859, when he was doubtful whether to enter the École Polytechnique or the École Normale Superieur, but by 1862 he had become a physicist and chemist. In 1875 he took up the study of bio chemistry and made researches by the side of his old master Pasteur at the dawn of the discoveries which were about to revolutionise medicine. About the same time he also studied meteorology at the Agricultural Institute and in 1883 published a treatise on Biological Chemistry, being from this date an intimate fellow worker with Pasteur. His book entitled 'Ferments et Maladies,' which appeared at about this time, is really a glorification of bacteriology and its prospects. Duclaux well foresaw the day when infectious diseases would practically cease their ravages and would not take toll of humanity by even a tenth part of what they did then. He worked indefatigably at every branch of microbiology, he taught at the Sorbonne, organised conferences in Paris and the provinces, founded the Annals of the Pasteur Institute in 1889, and kept alight the sacred fire among the students of microbiology. At the death of Pasteur Duclaux was chosen to carry on his work and then in 1896 it was that he published his magnificent work, 'Pasteur: the Story of a Genius.' Duclaux's next work was to attempt to codify in the work which was to extend to seven volumes all that was known about microbiology. Only the first four volumes have appeared but they comprise a veritable mine of facts concerning all that was known of the subject between 1899 and 1902. In the volume dealing with diastases he brings out his special knowledge of, and theories on, bio-chemistry. He insists on the fact that there are diastases of hydration and of dehydration, just as there are of oxidation and reduction, and it is well known to day what an important part the soluble ferments play as regards vital equilibrium. The latest works of Duclaux deal with social hygiene and with the relations of domestic hygiene and economy with chemistry. Duclaux belonged to the race of chemists who become medical men in imitation of the master whose toils have been the guiding star for their labours and it is fitting that regretful homage should be paid to the passing of one whose scientific work has been so valuable."

Medical News.

UNIVERSITY OF CAMBRIDGE.—The degree of Doctor of Science *honoris causâ* is to be conferred on Gustav Retzius, Emeritus Professor of Anatomy in the University of Stockholm, and Wilhelm Waldeyer, Professor of Anatomy in the University of Berlin. Mr. W. J. Sell, F.R.S., and Mr. H. J. H. Fenton, F.R.S., are to be appointed University Lecturers in Chemistry. At the congregation on May 12th the following degrees were conferred:—

Doctor of Medicine A. E. Carver, Clare.
Bachelor of Medicine B. Hudson, Clare, E. A. Ellis, Downing; and C. B. Goulden, non-collegiate
Bachelor of Surgery W. M. Mollison, King's, B. Hudson, Clare; E. M. Brown, Pembroke; W. V. Naish, Emmanuel, and C. B. Goulden, non collegiate.

UNIVERSITY OF DURHAM: FACULTY OF MEDICINE.—At the Convocation held on April 30th the following degrees and diploma were conferred:—

D [illegible]

D [illegible]

B [illegible]

L D S, William John Phillips, B Sc, Mary Raw, Frederick William Ritson, Constance Charlotte Robertson, John Malcolm Shaw, and Fred Stoker, College of Medicine, Newcastle-upon-Tyne, Otho Boyle Travers, Guy's Hospital, and William Frank Wilson and Hermann Wolfe, College of Medicine, Newcastle-upon Tyne

[illegible]

The Heath Scholarship founded in accordance with the will of the late Professor G. Y Heath has been awarded by the Professor of Surgery in the University of Durham to Mr. W. G. Richardson, M.B Durh., F R.C.S. Eng, of Newcastle-upon-Tyne, for his essay on "The Development and Anatomy of the Prostate Gland, together with an account of its injuries and diseases and their surgical treatment." This scholarship is awarded every second year and is of the value of £200. A further grant from the scholarship funds to the extent of £50 was awarded to Mr. Richardson to assist in the reproduction of the drawings which accompanied the essay and in the mounting satisfactorily of 70 wet specimens.

Royal Colleges of Physicians and Surgeons of Edinburgh and Faculty of Physicians and Surgeons of Glasgow.—The following candidates having passed the requisite examinations of the Conjoint Board were admitted Diplomates in Public Health :—

Arthur Morton Barford, M.R.C.S. Eng., L.R.C.P. Lond., London; Arthur Murray Wood, M B., Ch.B., Leith; John Christopher Thomson, M.D., Edinburgh; Margaret Merry Smith, M.B., Ch.B., Edinburgh; Chiranjiva Bharadwaja, L.R.C.P. & S.E., Edinburgh; Thomas Frederick Hillyer Blake, L.R.C.P. & S.E., Bournemouth: William Inglis Dunn, M.B., Ch.B., Edinburgh; Andrew Grant, M.B., Ch.B., Fortrose; James Leslie Marjoribanks, M.B., C.M., Edinburgh; James Andrew Hislop, L.R.C.P. & S.E., Glasgow; John Hally Meikle, M.B., C.M., Edinburgh; David Melville, M.D., Cape Colony; and William Alexander Reid, L.R.C.P. & S.E., Edinburgh.

At the same sederunt the following candidates passed the first examination in public health :—

Herbert De Carle Woodcock, L.R.C.P. & S.E., Leeds; Alfred Robert Maclurkin, M.B., Ch.B., Natal; Richard Staward, F.R C.S.E., Glasgow; Alexander Fraser Jack, L.R.C.P. & S.E., Glasgow; and James Allison, M B., C.M., Cambuslang.

David Dryburgh Gold, M.B., C.M., Markinch, passed the second examination in public health.

University of Oxford: Examinations for the Degrees of B.M. and B.Ch.—The Board of the Faculty of Medicine gives notice that in the subjects of human anatomy, human physiology, pathology, medicine, surgery, and midwifery in the examinations for the degrees of B.M. and B.Ch. the written part of the examination shall consist of one paper of six questions, only five of which may be answered, and that in the subject of forensic medicine and public health (the first examination in which, under the new statute, will take place in Trinity term, 1905) the written part of the examination shall consist of a paper of six questions, of which three shall be allotted to each division of the subject. The Board of the Faculty of Medicine also gives notice that the regulations as to certificates to be produced by candidates before admission to the second examination for the degrees of B.M. and B.Ch. (Examination Statutes, pp. 192–94) have been struck out and replaced by the following regulations which will first come into effect in Trinity term, 1905. Candidates for the several parts of the examinations for the degrees of B.M. and B.Ch. are required, at the time of entering their names with the secretary to the boards of faculties, to produce to him certificates showing that they have attended courses on, and have had practical experience in, the following subjects:—1. Human anatomy. 2. Practical histology and practical physiology. 3. Practical pathology. 4. Post-mortem clerk. 5 (*a*) Hospital practice, surgery; (*b*) hospital practice, medicine. 6. Mental disease. 7. Infectious disease. 8. Vaccination. 9. Attendance on labours. 10. Hospital practice. Forms for these certificates can be obtained from the secretary to the boards of faculties, from whom also detailed information as to the necessary requirements for a certificate can be had on application.—Dr. J. A. Ormerod has been nominated by the Vice-Chancellor and Proctors as examiner in medicine, *pro hac vice*, for the final examination for the Degree of Bachelor of Medicine, in place of Dr. Frederick T. Roberts, who has been granted leave of absence. Dr. J. F. Payne, who had been appointed, is unable to serve.

City of London Hospital for Diseases of the Chest.—The Lord Mayor presided on May 13th at the festival dinner held at the Hotel Cecil, Strand, London, in aid of the funds of the City of London Hospital for Diseases of the Chest. This hospital, which was originally founded in Liverpool-street more than 50 years ago, is now situated in the heart of the east end at Victoria Park; it contains 164 beds, more than 20 of which are unfortunately closed for want of funds. The secretary of the hospital, Mr. H. T. D. Ryder, announced in the course of the evening that the subscription list amounted to over £3000. After the Lord Mayor had proposed the usual loyal toasts, which were enthusiastically received by those present, Alderman and Sheriff Sir John Knill in a sympathetic speech submitted the toast of "The Medical Staff," which received an ample acknowledgment from Dr. G. A. Heron, one of the physicians to the hospital. The Lord Mayor next gave the toast of "Prosperity to the City of London Hospital for Diseases of the Chest." He made an earnest appeal on behalf of the institution and showed how during the past year 848 in-patients had been admitted into the hospital, whilst the attendances in the out-patient department for the same period of time reached the total of 63,079. Before concluding the Lord Mayor referred to the want of increased and proper accommodation for the nursing staff, a matter which had been frequently brought to the notice of the committee of management by the medical staff of the hospital and the council of King Edward's Hospital Fund for London. Sir William S. Church was intrusted with the task of proposing the toast of "The Committee and Executive Staff," which was responded to by Alderman Sir G. W. Truscott. The secretary, Mr. Ryder, was the recipient of many congratulations on the success attending the dinner.

Bristol Lunatic Asylum, Stapleton.—The visiting committee of the Bristol Lunatic Asylum in its report for 1903 states that on Dec. 31st, 1903, there were 838 patients in the asylum (386 males and 452 females). The highest number of patients resident at one time was 879. The committee adds that the condition of patients has been satisfactory and expresses its appreciation of the manner in which the medical superintendent (Dr. H. A. Benham) and the staff generally have performed their duties during the past year.

Literary Intelligence. — Messrs. Baillière, Tindall, and Cox announce for publication this week a translation by Dr. Thomas Johnstone of Professor Kraepelin's classic work on "Clinical Psychiatry," hitherto attainable to students of mental diseases in the German language only. The same firm announce a new work on "Organic Nervous Diseases" by Professor M. Allen Starr. The new text-book will contain 26 coloured plates besides 275 drawings in black. Messrs. Baillière, Tindall, and Cox also announce a ninth edition of Dr. H. Macnaughton-Jones's manual on "Diseases of Women" and a second edition revised and enlarged of Dr. Baruch's work on the "Principles and Practice of Hydrotherapy."

Presentations to Medical Practitioners.—At the George and Railway Hotel, Bristol, on May 8th, after the distribution of prizes and medallions to the successful candidates of the St. John Ambulance class of the Great Western Railway employés, Mr. H. F. Devis, L.R.C.P. Lond., M.R.C.S. Eng, was presented with a marble clock as a mark of appreciation of his services as honorary lecturer.—At a supper given by the Newton Abbot (Devon) division of the St. John Ambulance Association on May 11th the chairman, Mr. R. H. Grimbly, M.R.C.S. Eng., L.S.A, on behalf of the members, presented Mr. F. W. S. Stone, L.R.C.P. Lond., M.R.C.S. Eng., L.D.S. R C.S. Eng., with a case of pipes as a mark of respect and esteem on the occasion of his leaving the district.

Central Midwives Board.—A meeting of this Board was held at 6, Suffolk-street, London, S.W., on April 28th and adjourned to May 11th, when Dr. F. H. Champneys was re-elected chairman of the Board for the ensuing year and Mr. J. H. Johnstone, M.P., was re-elected honorary treasurer for the same period. Letters were read from the secretary of the Rotunda Hospital, Dublin, the general secretary of the Royal Academy of Medicine in Ireland, the Master of the Coombe Hospital, Dublin, and Professor J. W. Byers, physician to the Incorporated Belfast Maternity Hospital, asking the Board to reconsider its decision as to an alteration of its rules so as to allow pupil midwives trained in the chartered maternity hospitals of Ireland to be placed on the same footing as candidates for the examination of the Board producing the certificates prescribed by Forms III. and IV. in the schedule to the rules of the Board. It was resolved to reconsider the rules, so far as regarded the application contained in the letters, but a motion for replacing the certificates of personal attendance upon 20 cases by certificates of the master or senior medical officer of a hospital or institution where midwives are trained was lost. The further consideration of the matter was then adjourned to May 26th. After consideration of applications for certificates the names of 1037 women were passed under Section 2 of the Act and ordered for entry on the roll. The following shows the separate numbers of the various qualifications at present appearing on the roll: Royal College of Physicians of Ireland, 1; Obstetrical Society of London, 1213; Rotunda Hospital, 55; Coombe Hospital, 23; Queen Charlotte's Hospital, 73; Liverpool Lying-in Hospital, 20; British Lying-in Hospital, 3; Glasgow Maternity Hospital, 39; St. Mary's Hospital, Manchester, 78; Manchester Maternity Hospital, 1; City of London Lying-in Hospital, 7; Royal Maternity Hospital, Edinburgh, 6; Salvation Army Maternity Hospital, 4; National Maternity Hospital, Dublin, 1; women in *bonâ-fide* practice, July, 1901, 2928; total enrolled, 4452. It was decided to appoint, if necessary, an inspector to visit and to report on institutions applying for recognition of certificates or approval as training schools and the consideration of the scheme of examinations to be instituted by the Board was also proceeded with.

Medical Magistrate.—Dr. David Arthur Davies has been made a justice of the peace for the borough of Swansea.

The Welsh Medical Dinner.—The Welsh Medical Dinner will be held at Prince's Restaurant, Piccadilly, London, on Wednesday next, May 25th, at 7 o'clock, under the presidency of Sir John Williams, Bart., M.D. Communications should be made to the honorary secretaries, Dr. T. P. Beddoes and Dr. William Lloyd, at 63, Wimpole-street, London, W.

Devon and Exeter Dental Hospital.—The annual meeting of the subscribers to this institution was held at the Guildhall, Exeter, on May 13th, under the presidency of Prebendary J. G. Dangar, D.D. The annual report stated that during 1903 the patients numbered 4017. The financial statement showed a favourable balance of £21. The committee is anxious to have a new building so as to bring the hospital fully up to modern requirements and it has already received £1500 towards the building fund.

Fernley Observatory, Southport.—In his report for 1903 Mr. Joseph Baxendell, the director, gives in the usual convenient tabular form the condensed results of an immense number of instrumental readings. The general conclusion is "an unusually stormy, wet, and sunless year." The total rainfall was 39·52 inches, or 5·91 inches above the average, the year being the wettest since 1886. The heaviest fall of rain in any one "rainfall day"—i.e., 24 hours ending at 9 A.M. next day—was 1·78 inches on Sept. 10th, and a lithographed copy of the tracing taken for this period by Halliwell's recording rain gauge is inserted as a frontispiece to the report. From the paragraph dealing with the work of the astronomical observatory it appears that the general public are permitted to visit the observatory on any "starlight Monday and Wednesday evening" between Sept 1st and April 15th.

Yeovil Sewage Works.—A Local Government Board inquiry was held at Yeovil on May 10th into an application by the town council to borrow £8500 for additional expenses incurred in the completion of the sewage works. It was stated that the works had cost £31,206, which was over £8000 in excess of the sum originally sanctioned. As some necessary particulars were not available the inspector adjourned the inquiry *sine die*. In a report presented to the town council by the medical officer of health on the recent breakdown of the septic system of sewage disposal it was stated that the difficulty was a temporary one, due to the mechanical choking of the grit chamber with road refuse and trade refuse, such as hair and wool from the skin-dressing yards. He advocated the exclusion of this trade refuse from the sewers and its disposal at the factories where it was produced.

Volunteer Ambulance School of Instruction.—The annual banquet of the staff and members of the school took place at the Trocadéro Restaurant, London on May 12th, Brigade Surgeon Lieutenant-Colonel P. B. Giles, V.D., senior medical officer, being in the chair. The official guests were Surgeon General Sir William Taylor, K.C.B., Director-General of the Army Medical Service; Colonel A. T. Sloggett, C.M.G., Principal Medical Officer, Home District; Surgeon-General Don; Lieutenant Colonel E. M. Wilson, C.B., C.M.G., D.S.O.; Lieutenant-Colonel G. Robinson, commanding the Royal Army Medical Corps depôt at Aldershot; Mr. Jonathan Hutchinson, F.R.S.; and Dr. J. Galloway, a member of the Army Medical Advisory Board. The chairman was supported by Brigade Surgeon-Lieutenant-Colonel Andrew Clark, chairman of the Volunteer Medical Association, Brigade-Surgeon-Lieutenant-Colonel G. S. Elliston, Brigade Surgeon-Lieutenant-Colonel J. Adams, Brigade Surgeon-Lieutenant-Colonel Waterhouse, and many others. The toast of the evening, "The School," was ably proposed by the Director-General who laid great stress on the success of the staff, especially as regards the advanced or nursing class, the knowledge gained therein being of great use in the treatment of wounded after transfer to hospital. Brigade-Surgeon Lieutenant-Colonel Giles, in responding, thanked the commanding officers of the various metropolitan corps who had placed their headquarters at his disposal; he also thanked Major Maclure, the president, for his present of a handsome challenge shield which he had devoted to the nursing class. The year had been a successful one and the staff of the school was justly proud of the large class inspected by the Director-General. His thanks were due to the officers and non-commissioned officers' instructors for the *esprit de corps* which they had shown. Nearly 600 medical officers had passed through the school. Referring to the Royal [illegible] which would shortly be published, [illegible] Giles said that he had told the [illegible] Volunteers that increased allowances for medical officers were necessary when attending camp. Mr. Hutchinson and Dr. Galloway returned thanks for the guests. The toast of "The Royal Army Medical Corps" was proposed by Brigade-Surgeon-Lieutenant-Colonel Elliston and suitably acknowledged by Colonel Sloggett. The attendance was a good one and excellent arrangements were made by Surgeon-Captain E. M. Callender, the mess president.

Parliamentary Intelligence.

HOUSE OF LORDS.

Monday, May 16th.

A Revaccination Bill.

The Duke of Northumberland presented a Bill, which was read a first time, to provide for the revaccination of children after the age of 12 years.

HOUSE OF COMMONS.

Wednesday, May 11th.

Arsenical Poisoning.

Sir Cuthbert Quilter asked the President of the Local Government Board whether the conference between representatives of the Government departments concerned had yet taken place and whether he was in a position to announce what course he proposed to adopt to [illegible] f the Royal Commission on [illegible] the protection of the public [illegible] in beer and the fixing of a [illegible] Some preliminary questions [illegible] conference could take place. [illegible] I hope to arrive at a decision upon them very shortly.

Corporal Punishment.

[illegible] nt of the Local Government [illegible] nts inflicted on children who [illegible] and protection in Poor-law [illegible] y in the St. Giles's Receiving Home in January last who was returned to the Westminster Union [illegible] orporal punishment. [illegible] the case of a girl and [illegible] instrument shall be [illegible] case may require. The rules are, I think, sufficient usually to prevent [illegible] a case of excessive punishment is [illegible] o deal with any officer in fault in the [illegible] cumstances may be necessary. I may [illegible] ruises, &c., in the first case referred to [illegible] to have been caused by punishment [illegible] at all.

Thursday, May 12th.

The Lunacy Commission.

An interesting debate on the Lunacy Commission took place on the vote of £15 259 for that body.

Sir John Batty Tuke initiated the discussion by making an elaborate speech on the subject. He said he desired to draw attention to the inadequate constitution of the English Lunacy Commission and to certain defects in action consequent upon this inadequacy. In order to guard himself he wished to say in the first place that he did not desire to attack individuals. He believed that the various members of the Commission were eminent and hard-working men and that any imperfection in work followed entirely on the paucity of their numbers.

What was the constitution of the Commission? It was presided over by an unpaid chairman and there were four unpaid commissioners. There were three medical and three legal commissioners paid at the rate of £1500 per annum. The duties of the unpaid commissioners were confined entirely to the office. The main duty of the paid commissioners was to visit and to report on 114,000 registered lunatics in England and Wales. In order to develop his argument he trusted he might be allowed to compare the condition of things in Scotland. In Scotland there were one unpaid chairman, two medical commissioners at £1200 per annum, two deputy commissioners at £600, and two unpaid legal commissioners. The duty of this board was to supervise the interests of 14,500 registered insane persons. Thus, in England three medical commissioners supervised 114,000 patients, whereas in Scotland four medical commissioners supervised 14,500. Putting it otherwise, in England there was one commissioner to 38,000 lunatics; in Scotland one commissioner to 3622; thus the supervising power in Scotland was ten times more than in England. He might be told that there was another supervising body in England—the Chancery Visitors in Lunacy. But they did not come into the equation in any way whatever. Their duties were confined to looking after the interests of wards in Chancery and had nothing to do with the discipline or management of lunatic asylums as a whole. They might be put out of count. With these figures they were forced to one of two conclusions: either that Scotland was ridiculously overmanned or that England was seriously undermanned. He was going to say scandalously undermanned, and, on the whole, he felt justified in using that expression. He hoped that he would be permitted to adduce the result of 40 years' experience to show that Scotland was in lunacy matters not overmanned, and he would adduce four reasons gained from personal experience to support his opinion. First as to the character of the supervision. In Scotland each lunatic resident in an asylum was visited twice in each year by a medical commissioner who performed his duty thoroughly. In England there was only one visitation except in private asylums. He was going to say leisurely were it not that that expression might lead to misconception; but the fact was that twice in each year in Scotland each patient had an opportunity of laying his case before the Commissioner who attended to it carefully and gave it real consideration. In the second place, he wished to adduce the fact that no action at law had for 40 years come before the Scottish courts either under the Lunacy Acts or under the common law. Thirdly, they never experienced lunacy scares in Scotland. They had no scandals and outbursts of popular feeling or adverse press comments. Fourthly, he was warranted in the assertion that there was as much public confidence in asylums and their administration in Scotland as there was in general infirmaries and hospitals, and that was saying a good deal. All the conditions engendered a feeling of confidence between the Board of Lunacy and the asylum authorities. Commissioners would act at once should occasion arise. They would take steps to abate any scandal, but in his long experience he had never known of any serious case demanding intervention. And further, there was a confidence established between the commissioners and the asylum authorities on the one hand and the public on the other. In all these circumstances they were able to work elastically under a much milder law than existed in England; and this in its turn worked beneficially for the insane, for, after all, he thought it would not be gainsaid that their benefit was, or should be, the first object of legislation. The lunatic was not made for the law but the law for the lunatic. Now, on the face of it, he thought it would be generally admitted that it was physically impossible for the same kind and quality of supervision to be carried out in England as in Scotland. Was it possible for a commissioner, however competent, distinguished, and hard-working, to overcome ten times the amount of work done by his brother across the Tweed and to get equally good results? It was curious and interesting to note the fact that this numerical inadequacy of the English Commission was getting worse and worse. He did not propose to go back into the history of the dark ages, say the eighteenth century when humanitarian feeling had not been aroused, as shown by the state of our prisons, by the condition of our madhouses, and by the cruel administration of the criminal law. Public feeling was aroused at the end of the century by the great Frenchman Pinel, and by a sturdy Quaker of York whose name he had the honour to bear although he could not prove any close relationship. Partly as a result of their action, in 1832 five physicians and two barristers were appointed as a sort of Commission and these numbers were increased in 1842 to seven physicians and four barristers. Still things did not work satisfactorily and on the suggestion of Lord Ashley, subsequently Earl of Shaftesbury, a Royal Commission was appointed on the recommendation of which the present Board of Commissioners in Lunacy was established in 1845. He was quite content to support his argument from that date. Under that Act the Commission was established exactly on the lines on which it existed at the present day. In 1842 there was reason to believe, although accurate statistics were not available, that the number of lunatics in England and Wales was 25 000. Accurate statistics were only arrived at in 1859, when 37 000 lunatics were on the register. In 1870 there were 54,000 and in 1903, 114,000. Thus, medical commissioners had to do four times the amount of work at the present day that they had to perform at the date of the establishment of the Commission. This stagnation must, he thought, appear extraordinary to the House, which he could not help thinking would be anxious to increase the number. Now he would be reminded, of course, that besides three medical commissioners there were three legal commissioners. He admitted to the full that legal commissioners were absolutely necessary on the Commission. They could not be dispensed with as representing the law and the public. In the board room their presence was of the utmost importance. But what was their chief duty? It was to visit asylums along with the medical commissioner. The legal commissioner and medical commissioner hunted in couples, the legal commissioner knowing nothing more of medicine or of lunacy or of asylum administration than Policeman X. What was the theory of this visitation? It was a remnant of old tradition, the idea being that during visits to an asylum some points of law might arise which could only be settled by the legal commissioner. He challenged the commission to adduce a single case within, let him say, the last 40 years, in which such an emergency had arisen. Any irregularity could be detected by the medical commissioner and be reported and considered in the board room. As a matter of fact, the legal commissioner only stood by. Patients were not presented individually but *en masse*. He wrote a report and, in fact, performed the work of a clerk. He had heard it suggested that the legal commissioner superintended the action of the medical commissioner, but this, he need hardly say, was a ridiculous assertion. The former was useless for inspection purposes, he was an anachronism, and reminded him of the old story of the new commandant at Potsdam, who, on going his rounds, found a sentry in a curiously out-of-the-way position. He asked what was the object of this sentry. No one could answer him till the files of the orderly room were looked out and it was found that some 50 years before a Royal [illegible] tree which she desired to be taken care of an [illegible] The Princess and the tree were both dead b[illegible] He (Sir John) was convinced of the uselessness of these officers by his Scottish experience. There the legal commissioners confined themselves to the board-room and the inspection was carried out by one visiting medical commissioner. He might be told that the inspection of a legal commissioner gave confidence to the public. He had no hesitation in saying that there was not one in 10,000, perhaps not in 100,000, of the public that knew of his existence. As he had said, the legal commissioner was an absolutely necessary component part of the Commission in the board room but he was utterly useless in respect of inspection. He would ask the House to consider whether the performance of such duties as he had stated demanded the existence of three officers costing £4500 per annum. Surely one or two standing counsel at £500 a year each, or, as in Scotland, without salary, would be sufficient, and he was assured that in Scotland there was no shirking of work, no perfunctory performance of duties of those unpaid officials. Now he believed, in fact he knew, that an office undermanned to the extent that this was must work in wooden fashion. It must work bureaucratically, using the term in its worst sense. There was no sympathy, no elasticity; and, moreover, it worked under a hard law, and notwithstanding the rigidity of law and administration it did not command the same public confidence as the Commission in Scotland. The first step to obtain public confidence was to establish thorough supervision. That could be done by breaking England and Wales up into some four or five different districts, with a resident commissioner or commissioners in each. He would not say that they had better commissioners in Scotland, although they had men of great distinction on the Board. The success of their Commission was not dependent merely on the relative numerical superiority but on the fact that Scotland was a small country, where practically everybody knew everybody. If England were broken up into four or five districts with resident commissioners in each, these commissioners would, by the mere force of propinquity, know the character of each institution under their jurisdiction and obtain information as to the extent of unregistered and illegal establishments. As an illustration of what might be, and was going on, in [illegible] ould adduce the case of a man with no [illegible] prosecuted early this year for maintai[illegible] He had continued doing this for 13 [illegible] had seven patients all of whom were in a most miserable condition. This was not a single case. This could not have occurred in Scotland or in any district with a limited area. We are all deploring for humanitarian and economic reasons the rapid increase of lunacy in Great Britain. The rate ran up by thousands a year and had more than doubled in 30 years. In England, in the decade ending 1903, the annual average increase had been 2414. Whilst admitting that causes other than that which he was about to adduce had been in action, the reason to which he was about to draw attention for the increase of lunacy was the main one. We were manufacturing chronic lunacy day [illegible] asylums and the fault did not lie at the door of the [illegible] institutions, than whom no more earnes[illegible] existed. This was inevitable under the pr[illegible] and his argument was that we could not hope for any relaxation in this respect until public confidence was established, and the first step in this direction was the one he [illegible] indicated. It was not his intention to deliver a lecture on the [illegible] diseases comprised under the generic t[illegible] point out that medical men were prec[illegible] adequately during the two critical [illegible] beginning and the end of each case. [illegible] and efficiently amongst the moneyed classes and it would not be difficult to prove that as a consequence in these classes there [illegible] symptom[illegible] had to wait till the case was so pronounced as to warrant [illegible] thus losing the most valuable time during which the disease was most readily amenable to treatment. If of every 100 cases presenting themselves they excluded 20 as incurable, as *opprobria medicinæ*, of the 80 left 60 per cent. were amenable to treatment and that without asylum treatment. Inspectors could only adduce a concrete case in support of this assertion. An institution for the treatment of incipient cases of insanity had been established by the Glasgow county council and he found by its report that between 1890 and 1903 70 per cent. of cases treated were discharged cured. A proportion of cases of acute alcoholism—in itself a ripe cause of insanity—had been treated, but over and above a large number of incipient cases of insanity were treated to a satisfactory conclusion without being sent to an asylum. The London County Council was of the same mind. So convinced was that body of the necessity of such treatment that it promoted a Bill, introduced in another place last year, for the establishment of houses for this class of patient. The County Council sought for powers exercised in Scotland and not in England. In Scotland they were prepared for the increase of such establishments in consequence of general confidence in the Lunacy Board, but he doubted whether they were in England. He would allude very shortly to the other stage of the disease. A patient sent to an asylum was placed under the best conditions for recovery, but on his being discharged recovered he was in many cases utterly neglected. No term of convalescence was allowed, no after-care was possible except such as was afforded by one association in London, and accordingly [illegible] the asylum's recovery-rate of, say, 40 per [illegible] reduced to something like 25. Until they [illegible] dementia in the way he had explained the number of lunatics must increase and no material change could be brought about until confidence was established. The first means to that end was an efficient Lunacy Commission. They would go on

Sir MICHAEL FOSTER followed, associating himself warmly with the efforts of Sir John Batty Tuke to obtain an improvement in the lunacy laws. He considered that the urgent necessity for a large increase of the Commissioners in Lunacy was beyond doubt. Whether there should be an increase in the number of head commissioners or in

o the importance of the Bill he could not give a pledge that it would be reintroduced this session or next.

Sir E. STRACHEY considered the attitude of the Government unsatisfactory and he moved to reduce the vote as a protest.

The amendment was defeated by 216 votes to 126.

FRIDAY, MAY 13TH.

Ether for Manufacturing Purposes.

Mr. GRAY asked the Chancellor of the Exchequer whether his attention had been drawn to the fact that ether from pure spirit should be used in the manufacture of certain articles required by the War Office, that this spirit was subject to a heavy duty and hence if the articles were to be manufactured at a reasonable price methylated ether must be substituted for the pure or the contract sent abroad where manufacturers obtained spirit duty free for manufacturing purposes, and whether in these circumstances he would consider the desirability of permitting the manufacture of such goods in bond under practicable conditions or of allowing the price paid by the War Office for the duty received by the Excise.—The CHANCELLOR of the EXCHEQUER replied: Section 8 of

Notes, Short Comments, and Answers to Correspondents.

"DR." W. S. RICE.

A CORRESPONDENT has forwarded to us a selection of literature emanating from the quack who calls himself "Dr." W. S Rice and who lives at Stonecutter street, London; Adams, N.Y., U S A.; Boston, Mass., U S A, and Toronto, Ont, Canada. Rice of course promises cures in all forms of rupture and at any age, from infancy to men past 90 A personal examination is not necessary but cash must be sent with all orders unless "goods are to be shipped by Express C O D" Like all others of his kidney, he incloses testimonials purporting to come from persons who have been cured by his treatment and he also sends a booklet called "The Man Who Wondered Why." In this work he sets forth his views on the causation of hernia and on its cure by means of his "Lymphol" and truss and here they are. A rupture, it appears, is caused by the weight of the abdominal contents crowding through a break in the abdominal muscles. Supposing that the rupture is put back lymphol must be rubbed on. It penetrates the pores, stimulates the lymphatics calls them into action, and the stimulation of the lymphatics starts an increased secretion of lymph directly upon the calloused ring of the ruptured opening and fills it up with new flesh. In another pamphlet, "How to Cure Rupture," Rice says that lymphol will soften and lubricate the parts involved so that the rupture is safely, easily, and painlessly returned into the abdominal cavity. Rice, of course, is a pernicious quack, but just as the receiver sins equally with thief so are the proprietors of magazines and newspapers who insert Rice's advertisements, and those of the Pointings, McLaughlins, and their congeners, as much to blame morally as the quacks themselves. The quacks lie to the public for gain, the careless newspaper owners afford the quack the opportunities for lying and are paid for the facilities that they offer.

A QUESTION OF FEES

To the Editors of THE LANCET.

SIRS,—I should be glad to know whether magistrates have discretion as to the payment of a medical witness? The circumstances that give rise to the question are, briefly, these. A man with cardiac disease in the workhouse infirmary got upset and took his discharge against my advice When he appeared before the master the master demanded *24 hours' notice. He therefore presently fell into the hands of the* labour master who gave him work to do without first referring to me. After a little the man refused to do any more and became insolent and the labour master promptly had him arrested. The magistrates who saw him at once adjourned the case that I might appear. I did so and gave evidence as above and stated that in my opinion the man was

answer,

I am, Sirs, yours faithfully,

May 15th, 1904. E. C. T.

amounts.—ED. L.

A WORM IN THE EYE

The *St Petersburger Medicinische Wochenschrift* quotes what it calls a unique case reported by Dr Jewoski to the Yurjev Society of Naturalists He said that in February last a boy aged five and a half years was taken to him, who had suffered with eye trouble since September last, but only lately with pain and serious disturbance of vision. An examination revealed the presence of a bluish grey worm in the fore part of the eye just behind the cornea. It was about seven millimetres long and on its removal by an operation the lad's sight was rapidly recovered. Dr von Kennel, professor of zoology, to whom the worm was handed for more particular examination, reported it to be 7 4 millimetres long one millimetre in diameter, almost quite transparent, and in ten segments.

A CRYPTIC ASPECT OF THE CRY OF PAIN.

To the Editors of THE LANCET.

SIRS,—Your annotation (THE LANCET, April 23rd, p 1142) to my inquiry under the above heading should amply demonstrate to those who have good opportunities of observation that there still remains an unexplored work in a most interesting field of inquiry And the survey you make of the cry of pain in its natural habitat among other "expressions of emotion" together with your admission of failure to find any explanation bearing directly upon the point raised, will yet, I hope, bear good psychological fruit in inducing some readers to probe amongst the by-ways of their experience in connexion with suffering for some direct evidences of the effect produced in a sufferer's own psychical life by the auditory impression of his own cry of pain.

The candour of your admission with regard to published observations on this point has a special value for a psychological worker who has come upon a difficult and out-of-the-way aspect of a phenomenon which is in itself so common as the cry of pain. There is in such a subject the danger of struggling and straining in far-off places after evidences which may be as familiar as the light of day to the regular worker in the vicinity of extreme suffering. But this candour is in strict harmony with the spirit in which Darwin himself drew his conclusions in the "expression of the emotions" to which you make reference. Darwin evidently fully appreciated the difficulties of his subject and, far from dogmatising, he scrupulously cleared the ground for other workers. Take, for example, his emphatic warnings against looking at the expression of the emotions from an exclusively communicative standpoint; his insistence that, "on the contrary, every true or inherited movement of expression seems to have had some natural and independent origin. But when once acquired such movements may be voluntarily or consciously employed as a means of communication" (p. 356). Now, of course, the communicative values of the cry of pain may be left entirely unchallenged by the observer who notes the psychical value of the cry by way of the auditory impression made on the sufferer, nor, as far as I can see, need we controvert any view that may be held as to the importance to the sufferer of the sense of muscular effort in producing the cry. It is solely a question of fact.

Direct observation may prove difficult and results not very encouraging. The mere cry of pain can only at best produce an elementary sensation, a sensation which, at all events, has no power of competing with the psychical riches of the simplest articulate syllable of human speech. But *notwithstanding this psychical poverty in comparison* to other uttered sounds I appeal that the cry of pain should be observed and studied in the aspect suggested.

May I, Sirs, make one indication of a line of observation? A sufferer is sinking to a state of mental inertia. He utters a cry, a groan. *This cry or groan is a stimulus; it exerts some influence on* the sufferer's psychical life by way of his hearing. This is entirely beyond question. What remains to be done is to observe and to record this influence as closely as possible. Use the best means at the disposal of modern psychological observation to ascertain the full measure of this influence. *Does the sufferer's cry tend to arrest even for* a moment the oncoming of psychical inertia? Then record the fact and let it stand among the data of science. Cries of pain usher the human consciousness out of the psychical inertia of birth, then, so to speak, leave it for a while, but come again to usher it into the psychical inertia of death. Therefore I again appeal to workers in the vicinity of physical and mental suffering to observe this cryptic aspect of the cry of pain and I am of opinion that they may thus lend a hand in a most important psychological revelation.

I am, Sirs, yours faithfully,

London, May 11th, 1904. PSYCHOLOGUS.

HOLMAN TESTIMONIAL FUND.

THE following further list of contributions has been forwarded to us by the honorary treasurer of this fund, Dr. John H. Galton, Chunam, Sylvan-road, Norwood, S.E., by whom or by the secretary, Mr. W. A. Berridge, Oakfield, Redhill, Surrey, subscriptions will be received:—

AN ABNORMAL FŒTUS.

Mr. Edward H. Greaves, M.R.C.S. Eng., L.R.C.P. Lond., describes in the *Guy's Hospital Gazette* of May 7th a fœtus having the following measurements. total length, 23¾ inches; circumference of neck, 10 inches; circumference round shoulder, 20 inches; circumference round chest, 16½ inches; and circumference round pelvis at crest, 15½ inches. The fœtus weighed 30 pounds 4 ounces. The patient, a cowman's wife, three years ago gave birth to a child weighing 18 pounds. ' The labour was difficult but natural and not unusually long," says the narrator; "no instruments used or chloroform given and no injury to maternal parts." The child died during delivery. The mother believes herself to have been pregnant exactly 11 months.

THE SCOTCH OATH.

To the Editors of THE LANCET.

SIRS,—The Morecambe coroner is reported to have asked dozens of doctors why they hold their hands up to take the oath—Scotch custom —and they could not tell him. The answer is found in Genesis, chapter 14, verse 22, and sequel.

I am, Sirs, yours faithfully,

JAMES T. T. RAMSAY, L.R.C.P., L.R.C.S. Edin., &c.

Blackburn, May 16th, 1904.

FIRE-WALKING IN THE FIJI ISLANDS.

AT a meeting of the Anthropological Institute held on Feb 23rd the Hon. W. L. Allardyce, C.M.G., delivered an address the subject of which was the Fijians in Peace and War. An abstract of it published in the May number of *Man* gives some details relative to the practice of fire-walking which is performed only on the island of Beqa and by the members of a particular tribe. After a brief notice of the legend which describes how a certain family became possessed in perpetuity of the privilege of immunit[illegible]rom fire, Mr. Allardyce goes on to remark:—

> "The ceremony which is supposed to commemorate this event is conducted as follows: A circular pit is dug, three feet deep and 30 feet across; this is filled with alternate layers of timber and stones. The pile is kindled and burns for about 12 hours when the embers are removed by means of non-combustible vines and the red hot stones are levelled by means of levers made from similar materials. The 12 or 14 members of the privileged tribe come forward and walk round through the oven on the stones. The heat of the latter is considerable. A handkerchief laid on one of the stones was charred and a thermometer suspended over the centre of the oven registered 280 deg. Fahr., when the solder melted. Mr. Allardyce examined the feet of the performers both before and after the ceremony and was convinced that no preparation of any kind was rubbed on them. No signs of burning were discovered, and even the hair on the leg was not singed. The length of time occupied by this part of the ceremony is not more than a minute; the performers walk quite slowly. After this leaves and masawe are thrown on the stones and the latter baked and eaten.
>
> "As a partial explanation of this apparent immunity from fire the lecturer mentioned the fact that the village faces north-west and is consequently sheltered from the prevailing wind (the S E. trade), while it is exposed to the full heat of the sun. The natives are accustomed to walk about barefoot on the rocks when the latter are at such a temperature that an European cannot keep his hand on them, and in this way the soles of the feet become hardened. Doubtless the intense faith of the performers also contributes to their security."

To the foregoing account the editor of *Man* appends the following note:—"As an instance of the amount of heat which the foot, even of an European, will stand, I may mention that I have seen a cadet in the merchant service, who had been accustomed to walk about the deck bare-foot, hold a lighted wax match under his heel with the flame licking the skin until burnt out. He assured me that he felt no inconvenience from the heat and certainly no signs of burning appeared on the skin."

A NEW SPARKLET SYPHON.

AERATORS LIMITED, of Broad street Avenue, E.C., point out with reference to a notice of this syphon in our issue of May 7th that when traces of iron occur in the aerated water they are not derived from the spout but arise from leaving the steel bulb in position after emptying the syphon.

◆

J. A. H. F. will find in THE LANCET of Oct. 14th, 1899, p. 1055, the information he or she desires.

Mr. J. Warburton will find complete information in THE LANCET for the years 1871 and 1872.

G. P. writes:—Can any readers advise me what books I should read for the F.R.C.S. Edin.?

Mrs. Ll.—We do not give medical advice or recommend medical treatment.

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

Will Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them! Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, MR. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

The Lumleian Lectures
ON
SOME DISORDERS OF THE SPLEEN.

Delivered before the Royal College of Physicians of London on March 17th, 22nd, and 24th,

BY FREDERICK TAYLOR, M.D., F.R.C.P. LOND.,
SENIOR PHYSICIAN TO, AND LECTURER ON MEDICINE AT, GUY'S HOSPITAL.

LECTURE I.
Delivered on March 17th.

MR. PRESIDENT AND GENTLEMEN,—Since receiving and assenting to the request that I would deliver the Lumleian lectures this year I have experienced to the full the emotions which I gather other lecturers have on similar occasions sometimes gone through—a lively sense of the honour which you, Sir, have done me in asking me to deliver the lectures; a feeling of despair as to the choice of a subject which would be worthy of the occasion and of sufficient interest to serve for these lectures; the certainty that I should never be able adequately to deal with it; a determination to do my utmost to bring the matter to a successful conclusion; and, finally, the firm conviction that in that attempt I have largely failed. Still, in this last conviction I do not wish to be too hasty or to regard it as too deep-rooted and I shall be only too glad if your verdict on my efforts is somewhat more favourable than my own.

I have chosen for my subject Some Disorders of the Spleen, partly because I was under the impression that the disturbances of this organ were not too widely known and partly from the knowledge that a great deal of importance and interest has in recent years been ascertained. A subject of this kind—that is, the diseases of one of the organs of the body—can be treated in several ways or from several points of view—namely, the historical, clinical, coarsely anatomical, histological, and experimental. It will be at once seen that in the course of three lectures it will be impossible adequately to deal with the whole of such a subject and that either the extent must be curtailed or the lines of inquiry must be limited. I may say at once that I have attempted to deal with the subject from the clinical and coarsely anatomical standpoints so far as the material which I am able to bring forward is concerned, depending upon others for information as to the histology of the organ. Indeed, I can only regard this as a contribution to a subject which is yearly becoming ever larger and larger.

In order to get some idea of the frequency of the various lesions of the spleen I have had search made of the post-mortem records of Guy's Hospital during a period of ten years—namely, from 1892 to 1901—and I must here express my indebtedness to Dr. David Forsyth for the valuable assistance he has given me. They present a large variety, not perhaps a greater variety than might be found in any other organ, but a larger variety, I think, than is present to our minds generally when we are dealing clinically with our cases. In the ten years there were 4762 post-mortem examinations actually recorded and with but few exceptions the condition of the spleen has been noted. In an organ so variable in size and consistency as the spleen it is difficult to determine what deviations from the average shall be considered abnormal. But, including extremes of size and marked conditions of softness and hardness, there are more than 1800 cases in which the condition of the spleen might attract some attention. It will, however, serve no purpose to specify or to enumerate all the conditions of hardness or softness even amongst these, but it will be enough to deal with certain more pronounced conditions of disease. The pathological conditions of importance are those of inflammation, degeneration, growth, vascular obstruction and infarct, injury, and deformity, with which we are familar in other organs and the chief point of interest is to note the frequency with which certain lesions occur. The most frequent conditions to be noted are capsulitis, various kinds of positive enlargement, tubercle, and infarcts. And I propose to say a few words of some of these.

CAPSULITIS OR PERISPLENITIS.

One of the most frequent lesions of the spleen is inflammation or thickening of its capsule. Of the cases of capsulitis, or thickening of the capsule, 83 are reported as acute and 368 as chronic; a total of 451, or nearly 10 per cent. of all the cases examined post mortem. The condition probably has little clinical importance and the variety of conditions associated with it is so great that not very much information can be drawn from it at present as to its causation. This variety includes the diseases of the heart, lungs, and abdominal organs and, indeed, almost every kind of infectious disease. One sees apparently the explanation in any condition of local inflammation of vascular disturbance, such as a general peritoneal or abdominal lesion, in obstruction to its circulation and hence congestion, in heart disease, and in cirrhosis, and in a similar condition of affairs brought out, as we know it must be, by the infectious fevers. Hence in acute capsulitis, of which there are 83 cases, the following conditions are found (Table I.):—

TABLE I.—*Acute Capsulitis.*

Infectious diseases—		
Tuberculosis and phthisis	24	50
Typhoid fever	6	
Pyæmia	5	
Ulcerative endocarditis	4	
Pneumonia	3	
Broncho-pneumonia	3	
Pleurisy	2	
Suppurative meningitis	1	
Diphtheria	1	
Syphilis	1	
Heart disease		8
Cirrhosis of the liver		4
Renal disease		7
Cancer of the abdomen or the pelvis		5
Unclassified		9
Total		83

Among cases of chronic capsulitis, giving them in the same order, we have as under (Table II.):—

TABLE II.—*Chronic Capsulitis.*

Infectious diseases—		
Phthisis	26	94
General tuberculosis	24	
Tuberculous peritonitis	7	
Pneumonia	7	
Syphilis	7	
Malignant endocarditis	7	
Typhoid fever	4	
Broncho pneumonia	3	
Empyema	3	
Tetanus	2	
Diphtheria	2	
Malaria	2	
Heart disease		49
Cirrhosis of the liver		25
Renal disease		35
Cancers, chiefly abdominal		40
Chronic peritonitis, perihepatitis, and gall stones		16
Atheroma and aneurysm		17
Unclassified		92
Total		368

Contrasting the acute with the chronic, it is interesting to see some differences of conditions determining the event. Amongst the chronic there is a much larger group of unclassified causation—that is, of conditions the connexions of which with the capsulitis it is impossible to see or the frequency of occurrence of which is too little to enable one to draw inferences therefrom. Obviously also, while in the fatal illness the probable cause of acute capsulitis is before one, in chronic capsulitis the event may have taken place long ago and the fatal illness may really have nothing to do with it (Table III.).

ENLARGEMENT OF THE SPLEEN.

The next notable change is enlargement of the organ, which may arise from a number of causes. These may be roughly classified under (1) infections; (2) inflammations;

TABLE III.—*Relative Frequency of Causes of Acute and Chronic Capsulitis.*

—	Acute.	Chronic.
	Per cent.	Per cent.
Infectious	60·4	25·5
Heart disease	9·6	13·3
Cirrhosis	4·8	6·8
Renal	8·4	9·5
Cancers	6·0	10·8
Others	10·8	34·1*
Totals	100·0	100·0

* Includes 16, 17, and 92 in Table II.

(3) infarction; (4) passive congestion; (5) lardaceous disease; and (6) tumours, cysts, &c. The clinical aspect is inadequate—that is to say, I have only the records of five years' clinical cases and in them the number of large spleens found is but small. The figures, then, have this value only, that they show the relative proportions in which the organ is involved in different complaints as observed clinically. The figures I have are the following (Table IV.).

TABLE IV.—*Conditions associated with Enlarged Spleen.*

—	Enlarged spleens.	Per cent.
Typhoid fever	36	15·6
Leukæmia	25	10·8
Cirrhosis of liver	24	10·4
Lymphadenoma	17	7·3
Ulcerative endocarditis	15	6·5
Syphilis	11	4·8
Malaria	10	4·3
Mitral disease	9	4·0
Tuberculous disease	8	3·3
Pneumonia	7	3·0
Bronchitis	7	3·0
Splenic anæmia	7	3·0
Gall-stones	5	2·2
Anæmia	3	1·3
Various others...	48	20·5
Total	232	100·00

Among these others at the bottom of the list are cases of rheumatism, dysentery, acute nephritis, gastric ulcer, sarcoma of the lung, bronchiectasis, appendicitis, chronic peritonitis, carcinoma of the uterus, and perihepatitis. The list is not large enough to give information in more detail and all one can see in it when one has taken out the disorders sometimes regarded as primary diseases of the spleen—viz., leukæmia, lymphadenoma, and splenic anæmia—is the powerful influence of enteric fever, cirrhosis, and ulcerative endocarditis, and the somewhat less marked influence, or less frequent influence, of syphilis, malaria, and heart disease, represented especially by the mitral form. The records of post-mortem examinations give not much more precise information as to the size of the spleen in various cases, but of course the observations are limited to fatal cases and the proportionate frequency of actual occurrence cannot be expected to appear. Out of the total number of post-mortem examinations in ten years there were 379 cases of spleens of ten ounces in weight and upwards. They have been divided into several groups and may be tabulated as follows, but they do not include the special disorders already referred to—viz., leukæmia, lymphadenoma, and splenic anæmia.

On Table V. the following remarks may be made. Taking the spleens above 30 ounces in weight the largest spleen occurred in a case of cirrhosis and weighed 87½ ounces. The next two weighed 80 and 79 ounces in malaria and another malarial spleen was 53 ounces. The infective endocarditis spleens weighed 43, 35, and 30 ounces. The two typhoid fever spleens were 32 and 31 ounces. One large spleen weighing 72 ounces was associated with stricture and acute prostatitis; another of 63 ounces with gall-stones. The other great enlargements were in syphilis, cancer of the rectum, acute nephritis, atheroma, pneumonia, and in a case of rupture. In the spleens weighing from 20 to 30 ounces cirrhosis again stands at the head of the list with three of 28 ounces and one of 26 ounces, and another six weighed 21 or 22 ounces. Infective endocarditis has five spleens of from 26 to 28 ounces, typhoid fever two of 26 and 27 ounces, and in the two malaria cases it weighed 25 and 27 ounces. The other less well represented conditions are the same as in the preceding group, with the addition of phthisis (not lardaceous) three times, obesity, pyæmia, spinal abscess, and multiple thromboses. The examination of Table V. shows that among the very large spleens only a few causes are strongly represented—namely, cirrhosis of the liver, malaria, typhoid fever, and ulcerative endocarditis. In the middle-sized spleens these still hold an important place (except malaria), but others come to the front—namely, heart disease, tuberculous disease, and phthisis (apart from the production of lardaceous disease), and to a certain extent sarcoma and carcinoma of various organs. In the smallest sizes of large spleens the causes are much more evenly distributed. The four causes of great enlargement are no more strongly represented than are the three causative conditions last mentioned and the number of cases, in which the cause of death is not one of these and perhaps shows no apparent relation to the spleen is increasingly numerous. Of 129 cases not analysed in the preceding table a few disorders take a prominent part, although they are not so frequently represented as the others already selected. They are: pneumonia, with 11 cases; acute, chronic, tubal, and mixed nephritis, eight cases; atheroma, nine cases; granular kidney, 14 cases; and pyæmia, five cases. In a case of general pneumococcal infection the spleen weighed 12 ounces. Of these 129 cases nearly half—i e, 63—are definitely or presumably of an infective or microbic nature. This does not include the chronic and mixed nephritis. If these be added, as well as some surgical cases which may possibly have been septic (hernia, fracture, gall-stones, and thrombosis), there are then 78 cases out of 129, or nearly two-thirds, which are of this nature.

TABLE V.—*Showing common causes of Spleens weighing Ten Ounces or more.*

ATROPHY OF THE SPLEEN.

Before proceeding to speak further of the enlargements of the spleen which form such a common feature in its pathology I may say a word of the converse condition—atrophy—and of the growth in it of tumours. Of the spleens examined 80 weighed under three ounces (1·7 per cent.). Of these, 39, or nearly half, weighed over two ounces; another 27 weighed two ounces; leaving 14 under two ounces. This matter is quickly disposed of, as a very large proportion were in cases of cancer, of epithelioma, and of sarcoma. The first involved always the abdominal organs and showed 13 cases; the second, the alimentary and genito-urinary tracts, and showed 14 cases; while sarcoma was more widespread, with four cases, making a total of 31. Of the remainder there were ovarian cysts, two cases; herniotomy, six cases; fracture, six cases; granular kidney, three cases;

septicæmia, two cases; and burns, two cases; making a total of 21 Among the 80 cases of small spleens five occurred in quite old people of the ages respectively of 70, 72, 76, 78, and 80 years. The large proportion of new growths, amounting to three-eighths of the whole, is interesting. But it must be remembered that cancer and epithelioma of internal organs are also strongly represented among the enlarged spleens. There were, however, only 37 cases among 379 altogether—that is, 9·8 per cent., against 31 out of 80 small spleens, or 38 75 per cent. New growths, then, appear to operate against the enlargement of the spleen; and incidentally it may be remarked that this does not at first sight support the view of the infectious nature of these new growths. Or, to put it more guardedly, if subsequent investigation should show corresponding figures, the failure of the spleen to be enlarged would require special explanation on the theory of the infectious nature of cancerous new growths. These relations of the spleen are in accordance with the observations of physiologists upon the proportionate diminution of organs and tissues during inanition. In Voit's observations the spleen came next to adipose tissue in its percentage loss. In a cat killed after 13 days' deprivation of food adipose tissue lost 97 per cent., the spleen 67 per cent., and the liver 54 per cent. of the fresh organs. In 100 parts of dry tissues the spleen lost 63 per cent. and the liver 57 per cent. Researches by Tominaga on the amount of nitrogen loss during a prolonged starvation period in rats and rabbits showed the spleen at the head of the list, losing 98·48 per cent. in the rat and 67·06 in rabbits; but these results appear to want confirmation.

NEW GROWTHS IN THE SPLEEN.

Another point that I may pass quickly by is the occurrence of new growths in the spleen. This is comparatively rare; and if we exclude tubercles and the lymphoid masses occurring in Hodgkin's disease the cases of tumour or growth in the course of ten years probably amount to less than 1 per cent These include cretaceous and fibrous nodules and occasional gumma or hydatid cyst. Even cancer is rare and rare out of all proportion to its occurrence in the liver or kidney. In 677 cases of carcinoma, epithelioma, and sarcoma the spleen was affected only 23 times and the accompanying table (Table VI.) shows the site of the primary growth.

TABLE VI.—*Primary Lesion in 23 Cases of Malignant Disease of the Spleen.*

Carcinoma of the stomach	8	cases.
„ „ gall bladder	3	„
„ „ mamma	2	„
„ „ colon...	1	„
„ „ sigmoid flexure	1	„
„ „ omentum	1	„

Cancer of the ovary and rectum	1	„
Proliferating ovarian cyst	1	„
Sarcoma of the omentum	2	„
„ „ stomach	1	„
Total	23	

The remarkable prominence of the abdominal organs as the source of the cancer is perhaps what one would expect, seeing on the one hand its frequent origin in the epithelial structures there existing and on the other the great difficulties in the surgical treatment of cancer in this part. But it is also partly explained by the following considerations. Only seven times was it a case of true metastasis as far as the spleen was concerned. In the majority of cases, 16, the spleen was invaded by direct contact from other organs—the stomach, the pancreas, or the peritoneum Of the remaining seven cases, five of carcinoma, one of epithelioma, and one of sarcoma, the nodules were independent of adjacent or contiguous new growth. The primary growth in these seven cases was: in the gall-bladder, mamma (two cases), colon, sigmoid flexure, œsophagus, and stomach. Of course, this contrasts strikingly with the frequency with which abdominal cancer is repeated in the liver and it tends to show the influence of coarse transmission by veins and the absence of any general diffusion of any cancer germ cell or body throughout the circulation generally.

INFECTION AS A CAUSE OF ENLARGEMENT OF THE SPLEEN.

The relation of infection to enlargement of the spleen is well known and is illustrated by the results I have given. The most frequent causes of a really large spleen are enteric fever, malaria, and malignant endocarditis, while other frequent causes are pneumonia and tubercle. It is true that some of the largest spleens are produced under conditions not commonly regarded as, or at least not proved to be, infectious—namely, leukæmia, cirrhosis, splenic anæmia, pseudo leukæmic infantile anæmia, and allied conditions. But this very fact of the enlargement, coupled with the constant association of splenic enlargement, with various infections, justifies one in carefully considering how far they also may be determined by infections, unless it can be shown clearly that mechanical conditions are adequate to produce the swelling. The spleen in cirrhosis of the liver appears to be the typical example of an organ enlarged by passive congestion, and though it is possible, and is believed by many, that cirrhosis may be caused by a local infection, this is too far from being proved to disturb as yet this explanation of the state of the spleen. The support which the mechanical theory might be expected to derive from the fact that portal thrombosis or pylephlebitis adhesiva causes a large spleen is weakened by the suspicious relations between thrombosis and infection. The pathology of the spleen cannot be entirely settled by a reference to the clinical and pathological records of a general hospital, from which, for instance, are excluded designedly a very large number of the infectious diseases which occur. Had we the post-mortem results of scarlet fever, measles, and small-pox or typhus fever our list of enlarged spleens might be much more numerous. At the same time it must be admitted that clinically the enlargement of the organ in these diseases is not always an important feature. The following are recognised infectious diseases in which the spleen is known to be occasionally or constantly affected: typhus fever usually; enteric fever, relapsing fever, and malaria, with great constancy; measles and scarlet fever on the authority of Friedreich and Trojanowsky; variola; glandular fevers in more than half the cases; Malta fever always; diphtheria frequently; influenza; Weil's disease sometimes; and pyæmia. In anthrax the spleen is generally larger than natural, or half as large again, or double the natural size. In acute dysentery it is full and soft; in chronic dysentery it is markedly large but sometimes small. In beri-beri it is increased in bulk and weight but the influence of the failing circulation may here operate in part. In tubercle the organ often contains miliary or caseous nodules but it is also certainly enlarged sometimes. Congenital syphilis is probably, as shown by the results in phthisis, responsible for many enlargements in infants, as will be pointed out later. Tertiary syphilis causes gumma and lardaceous disease of the spleen. In leprosy it is stated that no naked-eye changes are present but bacillus-bearing cells may be found in profusion. Actinomycosis may invade the spleen from the bowel but the arrival of the germs by the blood-current is probably rare. I have already shown how often the spleen is enlarged in that obviously infective process pneumonia.

I have so far found little that is definite as to the implication of the spleen in rubella, varicella, mumps, whooping-cough, cerebro-spinal fever, dengue, cholera, sleeping sickness, early acquired syphilis, tetanus, rabies, glanders, foot and mouth disease, and rheumatic fever, and it is often expressly stated that the spleen is not enlarged in yellow fever, but Scheube states that it sometimes is enlarged, hyperæmic, and soft.

The spleen again appears to be little, if at all, enlarged by the different kinds of intoxication, whether by food poisons, snake poison, alcohol (directly), or by the different metals and chemical substances Dr. T. Oliver (in his article on this subject in Clifford Allbutt's work) expressly states that in phosphorus poisoning the spleen is not enlarged.

To the above infectious diseases may be added Landry's paralysis, which is highly probably an infectious disorder, and pernicious anæmia. Similarly splenic anæmia is under [illegible] extent Hodgkin's disease, [illegible] and rickets An interesting [illegible] Medical Association by Dr. George Carpenter may be here referred to.[1] He analysed 348 cases of enlarged spleen or splenomegaly in infants and children and the results have some bearing on our inquiry. I think it is clear that by the term "splenomegaly" he means only an organ presumably above the normal and it will also no doubt be admitted that the spleen is more easily palpable in infants than in adults and therefore a belief in its enlargement may be more readily entertained. Dr. Carpenter's line between normal and large spleens may therefore be drawn rather closer down than might in post-mortem cases be desirable. But the relative figures that he gives have considerable interest. Out of 340 cases he has reason to believe that 147 (or 42·2 per cent.) are due to syphilis, and another 131 were connected with rickets. Dr. Carpenter does not make too much of this last connexion. He says that anæmia is not necessarily present, rickets may exist without a large spleen, and rickets may get better and the enlargement of the spleen persist, or the rickets may get worse and the spleen get smaller. And therefore he regards splenomegaly as an epi-phenomenon. 66 of the cases showed no evidence either of syphilis or of rickets and were associated with the following diseases: pneumonia, broncho pneumonia, chronic pneumonia, tubercle, jaundice, ascites, enteric fever, ague, lymphadenoma leukæmia, congenital heart disease, and Parrot's nodes. This list reminds one of those I have above given and the infectious element is largely represented. He has not infrequently noticed the association of catarrhal jaundice with enlargement of the liver and the spleen. This might be explained by the obstructive enlargement of the *liver causing mechanical congestion of the spleen. But,* on the other hand, there are many points in favour of an infectious origin of ordinary catarrhal or simple jaundice, of which the existence of an epidemic jaundice is one.

---

[1] Brit. Med. Jour., August 29th, 1903, p. 463.

In a communication to the *Practitioner* (December, 1903) Dr. G. F. Still calls attention to the relations of congenital syphilis and enlarged spleen. He alludes to Gee as having said that one quarter of the cases of congenital syphilis show enlargement of the spleen and he refers to a recent article by Marfan [2] who finds splenic enlargement in half the cases of congenital syphilis. Marfan considers that syphilis is by far the commonest cause of splenomegaly in infants and that this splenomegaly is accompanied often by anæmia and by some enlargement of the liver and of the lymphatic glands. This brings us very close to the splenic anæmia of infants, of which I propose to speak later.

PHTHISIS.

There are two special forms of infection which are largely represented in the wards of a general hospital. Phthisis supplied 131 cases in which the spleen was affected. It has been already stated that 42 cases out of 379 of enlargement to 10 ounces and upwards were due to phthisis and tuberculous lesions. In phthisis alone 52 cases out of 131 were more than seven ounces in weight and were not lardaceous. In 19 the spleen was lardaceous, giving a percentage of 14·4. This corresponds sufficiently nearly with the general percentage of all organs for lardaceous disease in phthisis, which has been put at 10 and 20 by different writers. Only one further fact of interest comes out of this. The average weight of the lardaceous spleens was seven ounces and the largest of them 14 ounces, whereas the largest of the non-lardaceous spleens was 11 ounces and the average of them was 25 ounces.

INFECTIVE ENDOCARDITIS.

The tendency of infective endocarditis to cause enlargement of the spleen has already been shown. It is one of the four conditions which, apart from leukæmia and Hodgkin's disease, produce the largest spleens, the others being cirrhosis, malaria, and typhoid fever, and this in spite of the moderate shrinking which infarcts commonly undergo after a little time. The enlargement is obviously of the nature of an infective swelling, such as we see in typhoid *fever, malaria, and other infectious processes.* Some interesting figures come out here. Taking the whole number of cases of infective endocarditis in which the weights are recorded in the ten years 1892–1901 they amount to 77. The average weight of the spleen was 13 ounces. It has been already shown that 52 cases had a weight of ten ounces or upwards, and the greatest weights were 43 and 35 ounces; in another ten cases the spleens were seven ounces, eight ounces, or nine ounces; and in the remaining 15 only was the spleen below what may be regarded as an average weight. That the size was not determined by infarcts is shown by the fact that infarcts were present in spleens of five ounces weight only.

As to the changes that take place in the spleen as the result of infection it has generally been considered enough to say that the organ is in a state of inflammatory congestion. But it is interesting to note that the term splenitis is not in common use as applied to these changes, nor indeed is the idea of an inflammation so much as that of a temporary congestive process generally entertained. The rapid enlargement and subsidence in ague and the obvious dependence of the typhoid enlargement on the course of the fever will probably explain this, together with the fact that the termination is in nearly every instance subsidence or resolution. Of course, it is recognised that in special circumstances suppurative inflammation occurs. Dr. Robert Muir, in a communication to the Pathological Society of London,[3] gives an account of the most important changes in the organ in infections. He says: "The phagocytic activity of the cells in the pulp constitutes an outstanding feature" The cells concerned are the non-granular cells, partly hyaline leucocytes, and partly endothelial cells, so that there is a great increase in non-granular phagocytes. The swelling of the organ is in part due to accumulation of more or less damaged elements which are to a great extent destroyed. The elements chiefly destroyed are bacteria, neutrophile leucocytes, red corpuscles, and other degenerated cells. In the rabbit's spleen one can see non-granular cells containing as many as 20 or more red corpuscles and half a dozen neutrophile leucocytes in various *stages of disintegration. Neutrophile leucocytes* and red corpuscles also undergo extra-cellular digestion. Another feature of infection is the occurrence of myelocytes in the splenic pulp. This is especially the case in a severe form of infection, of which hæmorrhagic small-pox is an instance. A third condition is proliferation of cells. This affects to a very slight degree endothelial cells and the hyaline leucocytes in the pulp, but a more pronounced condition is one of proliferation of cells at the margin of the Malpighian bodies so as to form a distinct zone round the corpuscles and give them the appearance of enlargement. The cells involved are of larger size than lymphocytes and have a relatively abundant protoplasm, which is distinctly basophile in reaction. Dr. Muir thinks that these cells afterwards move outwards into the pulp. Gaylord and Aschoff give a similar account. A scraping, they say, shows small lymphocytes, large granular cells, pulp cells which resemble the large mononuclear cells of the blood, polymorphonuclear cells, and the sickle-shaped endothelial cells and distended elements, of which the protoplasm contains red blood corpuscles or fragments of the same. As compared with the healthy spleen the scraping shows more endothelial elements and more poikilocytic cells. Further, there are obvious degeneration and fatty processes going on. They lay more stress upon the phagocytic action of the endothelial cells and Dr. Muir attaches equal importance to either. The suggestion has been made that the spleen is likely to be larger in those infectious processes in which micro-organisms are actively circulating in the blood. This is at least borne out in the case of typhoid fever, malaria, relapsing fever, and infective endocarditis. Of these, as already pointed out, typhoid fever, malaria, and infective endocarditis provide a considerable number of the quite large spleens, while the organ is very constantly enlarged, if not very greatly, in relapsing fever. The organisms of typhoid fever malaria, and relapsing fever are constantly found in the spleen, while those of endocarditis maligna are well known to have been in the blood in a sufficient number of instances.

CIRRHOSIS AND SPLENOMEGALY.

In connexion with cirrhosis of the liver and its relation to enlarged spleen attention must be called to the occurrence of cases which have been described as splenomegalic cirrhosis I have been, I had almost said, guilty of publishing a case under this title. The culpability lies in the use of a word implying that an accompanying large spleen is distinctive of any particular form of cirrhosis, when it has been already shown that out of enlarged spleens more than one-eighth (13 8 per cent) are related to cirrhosis of the liver, when it is known that an enlarged spleen is a very common result of cirrhosis, and when it is shown that of 42 large spleens in cirrhosis six weighed 30 ounces or more, 11 from 20 to 29 ounces, and eight more from 15 to 19 ounces. The justification for its use is the fact that some cases occurred in which the spleen is exceedingly large. For instance, in a case which I published a few years ago[4] the spleen weighed at death 87½ ounces in a boy not quite 15 years of age and clinically it presented the shape, size, and position of a leukæmic spleen, occupying the whole left side and lower part of the abdomen and reaching four and a half inches across the middle line into the right iliac region. About the time of the publication of my case the subject was being discussed in Paris and divergent views were held as to the relations of the spleen to the liver, some at least believing that the splenic affection might be primary or at least antecedent to the hepatic cirrhosis. But even admitting the early appearance and predominance of the splenic lesion, it was possible to believe that some common source of infection in the intestine might act first of all, or more productively, upon the spleen, and so neither of them would directly cause the affection of the other, but the two would be results of a common cause. At that time M. Landrieux and M. Milian had recorded the case of a man in whom the cirrhotic liver weighed 1900 grammes (or 67 ounces) and the enlarged spleen 2700 grammes (or 90 ounces). It will be seen that in both these and in my case the spleen was large out of all proportion to the liver, although the liver was in each case far above the normal. The attempt to discriminate the cases of splenomegalic, meta-splenomegalic, and pre-splenomegalic cirrhosis, according as the splenic and hepatic changes were simultaneous or one in advance of the other, cannot be considered wise, as the time relations can only be observed clinically and the actual first change, whether in one or the other organ, eludes observation. But there are other interesting features in these cases—namely, the stunted growth of the individuals where the disease has begun in early life, pigmentation of the skin, and clubbing of the fingers and toes. Two of these—the clubbing or Hippocratic fingers and the stunted growth—are associated by Lereboullet[5] with the biliary cirrhosis and not directly with the splenomegalic element. Lereboullet, in his thesis on "Les Cirrhoses Biliaires," uses the term splenomegalic in reference only to the size of the spleen and obviously not as connoting thereby the seat of its commencement Indeed, he would obviously class my case as one of hyper-splenomegalic cirrhosis. And he divides all cases in the following way: (1) common hypertrophic biliary cirrhosis or Hanot's disease or splenomegalic biliary cirrhosis; (2) hyper-splenomegalic biliary cirrhosis; (3) micro-splenic or asplenomegalic biliary cirrhosis; and (4) atrophic biliary cirrhosis. Describing the organs as they are seen in biliary cirrhosis in general he says that the spleen macroscopically is voluminous, of variable volume, often losing bulk after a fatal hæmatemesis, of natural shape, often with more marked patchy splenitis, even with extreme cartilaginous plates. The tissue is sometimes soft and diffluent and at others firm, with a dark red section showing, but not always, an exaggerated development of Malpighian corpuscles. Often the appearance is only that of a congested spleen. In the case of Landrieux and Milian the surface presented numerous smooth projections where the parenchyma was firm, whilst elsewhere it was diffluent. Infarcts were also present in this case. In reference to the histological conditions Kiener, in a case which he has published, shows that the lesions were neither those of a cyanotic spleen (*une rate stasique*), as in ordinary cirrhosis, nor those of a spodogenic spleen—that is, one charged with the residues of destruction of blood globules, as in malaria and intoxication He found that the lymphatic system was affected and that there was a notable hypertrophy of the Malpighian corpuscles. The histological examination showed a reticulated tissue extremely rich in cells and this lymphatic hyperplasia prolonged itself along the arteries. He concluded that it was a lymphogenic spleen like that of lymphadenoma, tuberculosis, and other infectious diseases Lereboullet in the cases he himself examined found most often, especially in the most advanced cases, congestive conditions—the pulp gorged with blood and the Malpighian corpuscles, though distinct, but little hypertrophied; further, very little perisplenitis and little trabecular thickening. The last two conditions, however, predominated in the case of Landrieux and Milian. There was generally no material difference between the sections of splenomegaly and those of the hyper-splenomegalic organ. Sometimes the pulp is charged with pigment and at others this was absent. In reference to the nature of the cell structures in the pulp he allows that there is an excess (hypergenesis) of lymphoid tissue, but though this may suggest an infective association the predominant fact is, he thinks, congestion As to the important question of the relation of the enlarged spleen to the liver, Lereboullet ranks himself with those who regard the spleen, however big, and however long antecedent in its appearance to the hepatic enlargement and jaundice, as still affected as a result of the hepatic lesion and not as the primary cause. Admitting intoxications and micro-organisms as possible original causes he still thinks that it is from the liver that the spleen is affected and not the liver from the spleen. He sees no great difficulty in the conception of an infection being conveyed against the current of blood in the splenic vein; he attaches much importance to congestion as a factor in the splenomegaly; he shows that in any case the size of the spleen may vary a good deal so that the relative size of the two organs is not a guide as to which was first diseased; and he adduces the strong case recorded by Dr. J. Finlayson[6] of the three children in one family, all of whom had biliary cirrhosis, one with a large liver and a large spleen, another with a very large spleen and slightly hypertrophied liver, and the third with a liver and spleen equally enlarged. He claims as an important element that of age, these combinations occurring much more in children than in old persons. He makes the further proposition that "the spleen reacts to infections of the liver much more often and much more than it reacts to general infections This reaction is much more frequent than the reaction of the liver to the splenic lesion." And he goes so far as to suggest that cases of Banti's disease may have to undergo a revision from this point of view. The time for this scarcely seems to have arrived. His final conclusions are that biliary cirrhoses are the results of infection; that it is neither a general infection, nor an infection with the predominant localisation in the liver and spleen, nor an infection with the primary localisation in the spleen; but that it is "an ascending biliary infection due to germs proceeding from the intestines." The infection only becomes cirrhogenic in persons predisposed to it. An allied condition, perhaps an early condition, is that called by him splenomegalic jaundice, in which with a large spleen and jaundice there is a moderate enlargement of the liver. Several of the cases reported under this head have had typhoid fever or malaria in their former history. In my own case there was no opportunity of ascertaining the true relations of the splenic and hepatic enlargements These were both considerable when the patient first came under responsible observation.

DISORDERS OF THE BLOOD.

Among chronic splenic tumours besides those due to the infective diseases already specified we have certain diseases well known by name to all, but by no means exceedingly common, enlargements intimately connected with what may be called coarse changes in the blood but connected by links which may even now be held to be in great part missing. I refer, of course, to the spleens of leukæmia, of Hodgkin's disease, of splenic anæmia, and of the disease which has been burdened by the cumbersome name of anæmia pseudo-leukæmica infantum. The recognition of the leukæmic spleen in all but the earliest stages, and certainly in most cases, is easy, because leukæmia is a definite and distinct condition. The recognition of Hodgkin's disease also, so far as the spleen is concerned, does not as a rule present great difficulties—that is to say, that one will rarely be prepared to recognise a case of splenic enlargement as Hodgkin's disease unless some lymphatic glands were enlarged at the same time. And though it is, of course, conceivable that a case might occur with deep-seated, inaccessible, and unrecognisable lymphatic enlargements with manifest splenomegaly, I am not aware that attention has been called to a case realising this supposition. But splenic anæmia and infantile splenic enlargements present obvious difficulties which are by no means always solved clinically. I take the case first which occurs in infancy and early childhood. Are all the splenic enlargements associated with a little anæmia but without leukæmia or enlarged glands, to be called splenic anæmia? By common consent, no; and it has been the endeavour of numerous writers in the last few years to formulate the characters which shall distinguish a splenic anæmia from other groups of splenomegalic cases. The distinctive features which were first formulated were mainly in contrast with splenic leukæmia—that is, (1) anæmia, (2) enlarged spleen, and (3) absence of leucocytosis were the three chief features.

other conditions or organs than the spleen alone. Cirrhosis was a possible explanation of the enlargement of the liver and spleen Now, nearly eight years later, her health is bad; she had floodings until 12 months ago. Her legs were anæmic and pallid.

A consideration of all these cases shows that the diagnosis of splenic enlargement depends very little upon the condition of the spleen as such, but almost entirely upon the other associated conditions, especially the state of the liver, of the heart, and of the blood. The size alone it is which counts for anything, and this will be shown in the case of splenic anæmia and leucocythæmia splenica; in both of these the organ reaches large dimensions, which are, however, occasionally equalled in the case of splenomegalic cirrhosis and almost in infective endocarditis.

ON

ACUTE INFECTIVE GANGRENOUS PROCESSES (NECROSES) OF THE ALIMENTARY TRACT.

Delivered before the Royal College of Surgeons of England on March 21st, 23rd, and 25th, 1904,

BY EDRED M. CORNER, M.A., M.B., B.C. CANTAB., B.SC. LOND., F.R.C.S. ENG.,
SURGEON IN CHARGE OF OUT-PATIENTS, ST. THOMAS'S HOSPITAL; ASSISTANT SURGEON TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND STREET.

LECTURE III.[1]

Delivered on March 25th.

THE BACTERIOLOGY OF ACUTE INFECTIVE NECROSIS.

MR. PRESIDENT AND GENTLEMEN,—In the preceding sections it has been attempted to prove to you that lesions of a similar pathological nature, acute infective necrosis or gangrene, occur in the stomach, the duodenum, the small intestine, the cæcum, the appendix, the large bowel, Meckel's diverticulum, strangulated herniæ, and other forms of intestinal obstruction. To the naked eye the character of the lesion in perforated gastric, duodenal, and other ulcers, appendicitis, &c., is identical in each case. Hence the attempt has been made to urge singleness in the infective origin of the lesions The discussion of the various organisms found in the peritonitic fluid and elsewhere in examples of such conditions has been reserved for the third lecture, when from the bacteriology a further attempt will be made to show the universal activity of micro-organisms and the probable supreme importance of the rôle of septic cocci in the production of infective necrosis. It is also hoped that much has been done to remove from the walls of the alimentary canal their traditional character for delicacy and their proneness to become gangrenous on the least provocation. The tissues of the alimentary tract are, in fact, liable to exactly the same laws of life and death as the others which constitute the body. But owing to the natural septicity of the contents of the intestinal tract moist gangrene—i.e., septic death or necrosis—is infinitely more common than dry gangrene, i.e., aseptic necrosis, if the latter exists there.

It has been shown that the integrity of the wall of the bowel was in a similar position to that of any other tissue in the body and that its blood-supply may be considerably interfered with without causing its death or necrosis. Then the influence of infective organisms was illustrated and shown to be the cause of cases more rapid and acute than those in which there was only interference with the blood-supply. It is now my endeavour to bring some light to bear on the various organisms which enter into the fray. In 1891 Fränckel drew attention to the bacteriology of peritonitis. He showed that the exudate derived from the injection of an irritant into the peritoneal cavity was at first sterile, yielding later abundant cultures of organisms. He obtained pure cultures of the bacillus coli communis in nine out of 31 cases of peritonitis; in seven he obtained pure cultures of a streptococcus and in one a pure culture of a staphylococcus. In 1893 Tavel and Lanz published the bacteriology of 59 cases of peritonitis. Their results showed the presence of the bacillus coli communis in over 50 per cent. of cases, being about equally as frequent in pure as in mixed culture Streptococci came next in order of frequency, forming about 35 per cent. of cases, in which it was five times as often in mixed as in pure culture. Numerous other authors have published work since then, such as that by Hodenpyl, Welch, Barbacci, Malvosz, and so forth. Almost all of these authors found the bacillus coli communis to be by far the most frequent organism present and naturally have assumed it to be the cause of the peritonitis. Dr. H. P. Hawkins in his work on appendicitis took up the same attitude, but up to now the bacteriologists have not been guided in the interpretation of their results by the surgeon or clinician. Again, with the result of improvements in their science more accurate observations have been made. With these later methods Deaver publishes figures in his book on appendicitis from which the following percentages may be derived and which illustrate the differences in the bacteriology consequent upon the different clinical forms—namely, acute and chronic inflammation :—

Organisms.	I. Chronic appendicitis.	II. Acute appendicitis.
Bacillus coli communis	90 per cent.	70 per cent.
Ditto plus a staphylococcus	6 ,,	15 ,,
,, ,, streptococcus	Very rare.	7 ,,
Staphylococci	1 per cent.	4 ,,
Streptococci	Very rare.	Very rare.
Other organisms	3 per cent.	4 per cent.

The figures show very distinctly that pyogenic cocci are markedly more common in the acute than in the chronic forms both in pure and mixed culture, but, as might be expected, particularly so in the latter. A further distinction can be drawn as acute cases can be divided into those with a local abscess and those with diffuse infection or peritonitis. In the figures given by Deaver the pyogenic cocci are more frequently present with perforating than non-perforating ulcers of the appendix. Similarly, they are found more often in cases of diffuse peritonitis than with local abscess. When regarded from the clinical standpoint the figures seem to indicate that the more acute a case is, and therefore probably the earlier an operation is demanded, the more frequently are pyogenic cocci found. Barbacci, in 1892, proved experimentally that if almost any mixture of organisms are injected into the peritoneum and "sufficient time" allowed to elapse, only cultures of the bacillus coli communis could be obtained therefrom. This bacillus grows in common media with such rapidity and luxuriance that more slowly-growing organisms are swamped out and remain unnoticed.

In conducting a bacteriological examination with Dr. H. D. Singer[2] of a case of acute emphysematous gangrene the original cultures contained a streptococcus and a bacillus related to the bacillus coli communis and termed by San Felice the bacillus œdematis aerobius. The coccus was recognised in a 24 hours' culture and cover-slip preparations, but after that date it was lost owing to the rapid growth of the bacillus. If this is the condition in the laboratory it should be also the condition inside the body. Further experimentation with gangrenes and their organisms convinced me that these pyogenic organisms very materially assist the bacillus to obtain the start or impetus necessary in order for it to begin its career of ill and then the cocci may be lost entirely, being swamped out by the rapid growth of the bacilli. Mixed cultures were injected into guinea-pigs but only the bacilli were recovered, the streptococci being lost. Applying these two laboratory principles to the conduct of organisms in the body, it is to be expected that the earlier a culture is taken the higher will be the percentage of streptococci to be found in it. Secondly, in the case of acute local appendicitis there will be a higher percentage present than that found in chronic cases. And yet again, in a rapidly spreading infection with diffusion of peritonitis a yet higher percentage can be seen. Deaver's figures bear out all these considerations. And though one cannot regard it in consequence as proved there is ample circumstantial evidence upon which to base the suggestion that the pyogenic cocci are the great causes of acute infective necrosis and that later they are liable to be killed out by the growth of the bacillus coli communis and to be entirely absent from the cultures.

---

[1] Lectures I. and II. were published in THE LANCET of May 14th (p. 1334) and 21st (p. 1410), 1904, respectively.

[2] Transactions of the Pathological Society, 1901, vol. lii., pp. 42-60.

The previous reasoning answers very well for the case of streptococci, for though that is one of the most widely distributed of organisms it is very easily killed and lost in mixed cultures and may literally vanish before a member of the colon group. Staphylococci are a more various group which contains a number of very hardy members, tenacious of life. They are not nearly so easily killed and lost, and may even "stay out" the lives of the other organisms present in a mixed culture. One would therefore expect them to be found in peritoneal cultures more frequently throughout than streptococci are, and such is in reality the case. The figures bear out in every detail the statements which have just been made with regard to the various frequencies of the presence of staphylococci in chronic appendicitis, perforative and non-perforative appendicitis, appendicitis with localised abscess, or diffuse peritonitis. Moreover, in 4 per cent of acute cases and 1 per cent. of chronic a pure culture of staphylococci was obtained, apparently a very rare condition, indeed, with regard to streptococci. It is not easy to understand how the colon bacillus escaped culture.

The position that I would desire to put before you is this: that the action of organisms in the laboratory is carried out in the same way in the body and that surgery can come to the aid of bacteriology and interpret the clinical results and the actions. It is now disclosed that the more acute the case is the greater the abundance of the cocci of suppuration. The later the culture is taken the fewer these become if they are found at all. The obvious inference is that the first step in the pathological catastrophe of perforation is started by these pyogenic cocci, and owing to the subsequent "swarming" of our natural guest, the bacillus coli communis, their traces are hidden and they themselves very often die. In the paper with Dr. Singer, previously mentioned, it was found that the septic organisms in cases of mixed *infection* (of traumatic gangrene) are responsible for the bronzing of the skin which precedes the spread of the gangrene and seem to act as forerunners, injuring the tissues and rendering them an easier prey to the specific bacillus. The action is the same in the walls of the stomach or appendix as in the arm or leg, with the great exception that the thinness of the walls of the former results in their perforation and in the infection of so vast an absorptive surface as that of the peritoneum. A complete parallel exists between the known septic diseases of the skin and those largely unknown of the mucous membranes of the alimentary tract. An infection from the interior of the bowel, like that on the surface of the skin, by its very nature must be "mixed," consisting of many organisms, and must contain nearly always the vastly predominant organism of the bowel, the bacillus coli communis.

There is, however, a further lesson to be learned which is of such importance that I may be excused for mentioning it here. The presence of the bacillus coli communis is so widespread in our alimentary canal that no matter what organisms can grow there, it multiplies so rapidly that it must overcome other organisms and may exterminate them. Applying the same reasoning which has been used for the processes which go on in the laboratory and the pathological processes in the peritoneal cavity outside the intestine to the normal processes which take place inside the intestine, we are forced to realise that the bacillus coli communis will tend to destroy all invaders. And as when within the lumen of our intestines it is harmless to the tissues, it is beneficial to the individual, it must be continually saving us from innumerable ills by destroying harmful bacteria. Its action may be likened to that of the leucocyte in the tissues and the bacillus coli communis becomes recognised as our best friend, the knight-errant of our intestines, the phagocyte of our bowels. But as with all friends, evil communications corrupt good manners; on occasions intercourse with streptococci and staphylococci lead to its wildly rushing in the breach which these organisms have prepared and then the leaders of the insurrection are ruthlessly trampled on and killed out by the rabble of lusty bacilli which follow in their wake. History is repeated in the actions of the bacilli of our alimentary tract and revolutionary leaders are killed by the very rabble they raise. One point further, as a consequence of the above it is doubtful if the cultures made from a case represent all the organisms that have been concerned in the disaster. Caution must be always exercised in making deductions from the results so obtained.

Mr. W. Watson Cheyne in an admirable article upon inflammation says: "The effects of the organisms on the tissues vary with the kind that is introduced; for example, the staphylococci tend to form circumscribed abscesses, while the streptococci are especially concerned in the production of diffuse spreading suppuration." This is, of course, a perfectly general statement. Both kinds of pyogenic organism acting on a comparatively thin-walled organ like the stomach will be very apt to cause a perforation. But the action of the former will be to produce a local perforation, whilst that of the latter will produce perhaps a perforation which is merely a local sign in a more widely spread area of infection. In the former case the infection and perforation involve the same area; in the latter the perforation is but one part of the infection. Dr. W. Cayley, in the Transactions of the Pathological Society of London, 1902, p. 282, records a case of streptococcus infection of the stomach, phlegmonous gastritis. The change was especially noted in the pyloric end. [illegible], although the [illegible] diapedesis of [illegible] pneumococcic gastritis on p. 286 of the same volume. In this the mucous membrane was necrosed, contrasting with its more or less healthy condition in Dr. Cayley's case. Again there was no perforation. Cases of epidemic streptococcus enteritis have been described, notably by Booker,[3] which have not been at *all necessarily fatal. Streptococci* can give rise on the skin to erysipelas which is a capillary lymphangitis; they can also cause cellulitis or a lymphangitis of the cellular tissue. The former is transient and can disappear entirely and I cannot help thinking that many acute gastrites, appendicites, and enterites are of a similar erysipeloid nature. The subject of the identity or relationship of the streptococcus erysipelatis with ordinary streptococcic suppuration will not be entered upon.

The tale of the staphylococci is different and an organism which *typically causes* a circumscribed abscess will in the gastric or intestinal walls cause a local perforation. These cocci are hardier than the streptococci are and will, I believe, be found to be the chief cause in the production of the acute infective necrosis of the alimentary tract. Of direct proof I can offer none, as my own unaided bacteriological efforts were such as could only be managed in moments snatched from the extremely busy life of the resident assistant surgeon of St. Thomas's Hospital, and though I have made a number of examinations in cases of peritonitis, the exudation in strangulation, both inside the abdomen and in hernia sacs, they are such that, though they may guide my ideas, I do not consider them worthy of being brought forward. It may be mentioned that my results guided me to the belief that pyogenic cocci will be found to be the great originators of perforations and gangrenes of the alimentary tract and also to the uniformity of the pathological process, acute infective necrosis, in appendicitis, perforated gastric, duodenal, and other ulcers, strangulated herniæ, &c

THE BACTERIOLOGY OF STRANGULATED HERNIÆ.

Bundschuh[4] found bacilli present in the fluid in the sacs in 60 per cent. of cases. Apparently this was the bacillus coli communis. The observations which I was able to complete were 15 in number. Cultures were only obtained in about 33 per cent. of cases. But the result seemed to depend mainly upon two factors—namely, the severity and the duration of the strangulation. The presence of the bacillus seems to make no difference in the prognosis or the primary union of the wound. Professor Welch years ago demonstrated the presence of the bacillus coli communis in surgically clean laparotomy wounds. It is therefore possible to go further than the usually enunciated dictum that "all work goes to show that this organism is not pathogenic when it is present in the normal intestine, but when the intestine is injured or the organism enters an unusual or abnormal situation of the body it can set up various lesions."[5] To this may now be added that it has been found in the peritoneal cavity in cases of intestinal obstruction and in the sacs of strangulated herniæ without producing any obvious result from its presence. It may not have been doing harm in a number of places where it has been found. In a case of acute infective necrosis in a strangulated hernia, reported for the first time in these lectures, "cocci" were found in the cover-slip preparations as well as bacilli, but in the cultures only bacilli were found. It is therefore not clear that, unaided, the ordinary colon bacillus of our intestine does us more harm than good. In fact, I believe that it does us infinitely more good than evil and certainly is a much libelled organism. The ordinary colon bacillus has many relations, some of whom can be extremely badly behaved. It is by no means easy to make sure of the "ordinary bacillus coli communis." The dependence for the initial start of the action of the colon bacillus on the bowel wall upon "injury" alone is not so decided as has hitherto been taught. The proof of its existing without apparent harm in the tissues, as in intestinal obstruction and strangulated herniæ, has been adduced. Again, by the action of the bacillus typhosus in enteric fever the mucous membrane of the bowel is injured, and though in this disease the colonies of bacillus coli communis seem, or are said actually to be, numerically increased, yet perforation and gangrene of the bowels are not so common. Yet, again, in tuberculous enteritis, perforation and gangrene are not nearly so common as would be expected if the bacillus coli communis merely needs the tissues to be "injured" in order to begin its work of havoc upon them.

---

[3] Centralblatt für Bakteriologie und Parasitenkunde, 1899, Band v., S. 316.

[4] Beitrage zur Klinischen Chirurgie, Band xxxi., Heft 2.

"It was formerly taught that there were no micrococci in the intestines. Recently they have been demonstrated." So says a recent bacteriological text-book. And there is every reason why they should not be found in ordinary cultures, and perhaps even on cover-slip preparations, being or having been killed out by the growth of the colon bacillus. Yet I believe that we must look to pyogenic micrococci for the starting point of cases of acute perforation and gangrene—i.e., acute infective necrosis—in whatever part of the alimentary tract they may be situated.

THE RELATION TO PHAGEDÆNA, CANCRUM ORIS, &C.

With the wild ardour of youth I once set out to attempt to elucidate the bacteriology of gangrenes, phagedæna, cancrum oris, &c. The sobering effects of this attempt lie in two chief directions. Firstly, in all cases a mixture of organisms was obtained and in the process of isolation and separation of these bacteria one either lost a lot of the organisms or they in varying degrees their power of producing disease. And, secondly, I do not believe that it is possible to attribute these diseases to the result of the action of any specific organism or even organisms. These infections are of their very nature and situation "mixed" infections, and the omnipresent and over-represented organisms in them are the pyogenic cocci—that is to say, they are pre-eminently septic infections. Bacteriology, as it now exists, offers at the best but an incomplete account, and, as has been said in a recent bacteriological text-book, "it should be borne in mind that many of the bacteria which can be obtained in coverslip preparations cannot be cultivated." And it may be added that many, even the most important, may be lost before the cover-slip preparations can be made. Oberwarth[6] records a case of primary gangrene of the tonsil which proved fatal. Streptococci were alone found in the culture. In fact, streptococci and staphylococci are acknowledged to play a leading part in gangrenous dermatitis, stomatitis, tonsillitis, &c., but owing to the vigorous growth of the hardy bacillus coli communis their importance has not as yet been recognised in gastric and alimentary necroses and therefore direct proof is still wanting. It is of considerable interest and supports my suggestion, that in situations such as the tonsils whence cultures need not be crowded out by the bacillus coli communis, if it is present at all, pyogenic cocci alone or predominantly are found. This may be regarded as another item of circumstantial evidence in favour of the primary action of pyogenic cocci in the production of acute infective necrosis of the stomach, duodenum, appendix, &c.

ACUTE INFECTIVE NECROSIS IN VETERINARY WORK.

It is my desire to bring home to my hearers the value of a careful examination of the records of veterinary surgery and pathology. A most fascinating study is afforded in this way and one which will do much to aid and to extend the experimental researches. Acute infective necrosis occurs in animals in the shape of gangrene of tracts and perforations of the alimentary canal. Unfortunately, as yet, veterinary pathology is not in so advanced a state as is human pathology and the records and descriptions are consequently sometimes difficult to understand. Speaking generally, the diseases of animals are not as yet well worked out. But the future will doubtless furnish far greater stores than the somewhat meagre accounts now available.

Thrombosis of a mesenteric vein.—I found the record of one case of mesenteric thrombosis in animals described by Connochie in the *Veterinary Journal* of 1898, vol. xlvi., p. 324. The title of the paper is "Vomition in the Horse due to Mesenteric Embolism" and is very misleading. The subject was a valuable hackney filly, rising three years old, which was in good condition. For two days she was noticed to be eating sparely; on the third day she was found lying down and rolling over and over, and the fourth day she died. At the post-mortem examination an ante-mortem clot was found in the anterior mesenteric vein with resulting gangrene of the "intestines." The case in reality seemed more acute than many of those of venous thrombosis occurring in man.

Suppurative typhlitis.—A case of typhlitis such as must correspond with our appendicitis was also found and is reproduced in this section. A horse was suddenly seized with violent colic and died in "some" days. At the necropsy "a quantity of reddish serum was found in the abdominal cavity with flakes of lymph upon the intestines. On removing the cæcum there was found at the place of attachment an induration from one to two centimetres thick, and in this an abscess of the size of a 'nut' which contained grey, thick pus. Along the whole extent of the crook of the cæcum the wall of the gut was thickened. The mucous membrane was very much inflamed, deep red in colour, the epithelium came away in flakes leaving a blackish corium." The importance of this case in corresponding to appendicitis in man has been remarked on in that section of the second of these lectures, 1904.

Perforations of the stomach.—Perforated gastric ulcer in animals is a subject covered with much confusion. Acute abdominal disease in animals seems largely to consist of three kinds—namely, colic, ruptured stomach, and twisted guts. From the descriptions it is not easy always to decide upon the case as to whether the condition was inflammatory or the result of true bursting of the stomach which does occur in animals. Three genuine cases were found.

CASE 1.—(*Journal of Comparative Medicine*, 1897, vol. xviii., p. 716.) A horse died from "colic" but was found to have an irregular zigzag ulceration along the greater curvature of the stomach. There was also another ulcer near the pylorus. In the first ulcer was a perforation about one inch long which had caused peritonitis and death.

CASE 2.—(John Freeman, F.R.C.V.S., the *Veterinarian*, vol. lxxiv., 1901, p. 108.) A Scotch deerhound had been ailing for some time with wasting. At first the diagnosis was that of worms, later pernicious anæmia. Post mortem a perforated gastric ulcer of the size of a half-crown was found. The other viscera were healthy.

CASE 3.—(Mosser, *Bulletin de la Société Centrale de Médecine Vétérinaire*, Feb. 23rd, 1903.) At the post-mortem examination of a cow, from 10 to 12 ulcers were found along the greater curvature of the stomach, varying in size from that of a pea to that of a franc piece. One of these had perforated and caused peritonitis and death.

Ruptures of the stomach have been reported in far greater numbers than have true perforations and occur always along the cardiac end of the greater curvature, being sometimes as much as 18 inches long. Mr. Malcolm, F.R.C.V.S., says that it is not an infrequent occurrence and that it is due to the violent contractions of a relatively small and weak stomach which cannot relieve itself by vomiting. In a certain number of these ruptured stomachs there is evidence of previous pathological change. For instance, in the case of Littlewood, *Veterinarian*, 1894, vol. xxxiv., p. 291, the walls were thickened and softened by parasites.

Perforation of the small bowel.—Professor Penberthy in the *Journal of Comparative Pathology*, 1896, p. 25, says that in enteritis "mortification may occur in 8–10 hours." Such rapidity demands the assumption of the action of micro-organisms. Perforations of the small bowel seem more common than they are in any other situation. In the *Journal of Comparative Medicine* H. H. Dell records a case of three perforations in the ileum, associated with the presence of tænia saginata. The subject was a Gordon setter bitch. He quotes Cadeac, *Revue Vétérinaire*, 1888, as reporting a case of perforation in the duodenum of a terrier due to a "tænia." Lahoque, *Recueil Vétérinaire*, 1888, describes three perforations in the small bowel of a dog due to tænia serrata. In the *Journal of Comparative Medicine*, 1899, vol. xx., p. 379, it is reported that a seven-year-old bay mare died and at the post-mortem examination a perforation of the ileum half an inch in diameter was found and general peritonitis. The ulcer was solitary and there was no obvious cause.

[6] Deutsche Medicinische Wochenschrift, April 23rd and 30th, 1903.

Perforations of the large bowel.—Captain Martin, in the *Veterinary Journal*, 1903, N.S., vol. vii., Part 41, p. 273, gives a most interesting account of a unique case. A chestnut mare was found to have an intense inflammation of the cæcum, or typhlitis with perforation, and through that perforation a number of coils of small intestine had passed into the cæcum and become strangulated. Davis (*Veterinary Journal*, 1897, vol. xliv., p. 170) says: "The 'floating colon' was found to be greatly inflamed over a patch about eight inches long and perforated. A calculus of two and a half pounds weight was free in the abdominal cavity." Professor Dewar (*Veterinarian*) says: "A gelding, eight years old, was found post mortem to have a 'ruptured' colon ten inches in length. The walls were three to four times as thick as normal." Neyland and Leblanc (*Veterinarian*, 1896, vol. lxix., p. 48) says: "Post-mortem examination on a mare who had had 'colic.' One metre from the anus the gut was ruptured, the 'tear' being ten inches in length, and a large intestinal calculus was in the perforation."

Peritonitis in animals.—The natural thing to look into to find support for the previously recounted cases was to refer to the records of cases of peritonitis and abdominal abscess Unfortunately, the origin of these diseases is not always known or looked for. For instance, in the *Veterinary Journal*, 1900, N.S., vol. i., p. 295, a report of a case is given from the *Berliner Thierarzt Wochenschrift* of a cow which had a large abscess in the peritoneum which discharged per rectum. There was "quite a litre of greyish-yellow, stinking, filthy pus." The sinus closed and the animal recovered. The origin of the abscess is not known, but had [illegible] the importance in the veterinary world that it has with us. Brett (*Veterinarian*, 1889, vol. lxii., p. 619) says that peritonitis is not common in cattle. And he gives accounts of three cases which were diagnosed as fæcal impaction. Post mortem, two were called idiopathic peritonitis and the third was regarded as due to "cold following calving." Littlewood, in the *Veterinarian*, 1890, vol. lxiii., pp. 204–07, describes an epidemic of peritonitis which occurred among the horses of the Egyptian police reserve in which about 14 horses died from peritonitis for which no cause was demonstrated. Poisoning was excluded. All cases were acute and the only definite thing noticed was that the inflammation was mostly in the pelvis and the "double colon." Wohmuth (*Veterinarian*, 1901, vol. lxxiv., pp. 29–31) records three cases, one being due to a nail in the rumen, another to an abscess in the wall of the rumen, and the third consequent on parturition. The other records merely illustrate its occurrence after operation or parturition.

Looking through these cases veterinary surgery seems in the same state as that in which the surgery of mankind was some 20 years ago. The idiopathic peritonitis of the latter has turned out to be mainly due to the disease of the appendix which our predecessors had overlooked. It remains with the future to see if those of the animal will find a similar explanation. In discussing the pathology and physiology of the cæcal region it was shown that there was every reason to expect inflammation in this place and also the presence of lymphoid tissue. Beyond the influence of diet and position there seemed to be no particular reason why this region should be very often affected in the biped, and escape in the quadruped. It is to be expected that the disease when closer attention is paid to it will be far more frequent in the latter than it appears to be. Veterinary surgeons have not as yet recognised anything of the kind. It has also been shown that the collection of lymphoid tissue in the caput coli of animals is the analogue of the appendix of man. And, therefore, it should also have some analogous diseases. It must have a somewhat similar rôle with regard to the action and growth of micro-organisms. And it will, therefore, be liable to like inflammatory changes. These have not been fully recognised, but I have brought forward a case of abscess of the wall of the cæcum, examples of localised intraperitoneal abscess near it and in the pelvis, and peritonitis limited to, and especially marked in, the same region. And it is suggested that these have an origin analogous to what they would have in man—i.e., the appendix, in the lymphoid tissue of the cæcum. Professor Clifford Allbutt once wrote to me: "I warmly welcome any attempt to get away from anthropocentric medicine, to escape from the ptolemaic phase into the cosmic." Let this sentence close the remarks that I have made upon the subject.

ON THE SURGICAL TREATMENT OF DISEASES OF THE STOMACH FROM A PHYSICIAN'S POINT OF VIEW.[1]

BY JOHN LINDSAY STEVEN, M.D., F.F.P.S. GLASG.,

PHYSICIAN TO, AND LECTURER ON CLINICAL MEDICINE AT,
GLASGOW ROYAL INFIRMARY, MEMBER OF THE
GENERAL MEDICAL COUNCIL, ETC.

THERE is no subject of greater interest to the general physician than that concerning the surgical treatment of the diseases of the stomach with which he is called upon to deal and in my opinion there is no department of the surgeon's art which has made greater strides within recent years. The comparative safety with which the stomach can be exposed and manipulated, the perfection of the technique with which the operations are carried out, and the relief which in many cases of gastric disease is afforded by surgical interference compel the physician to regard the surgery of the stomach as one of the therapeutic procedures which he must always take carefully into consideration in guiding the treatment of cases of gastric disease. The technique of the operations is, indeed, so perfect that on at least one occasion, some months after a laparotomy had been performed for cancer of the stomach, I have seen the abdomen opened on the post-mortem table without the pathologist having noticed the almost invisible cicatrix which was all that remained as evidence of the operation that had been performed. It is no wonder then that the surgeon is ready and willing to give the sufferer from organic disease of the stomach all the benefit that may be possible from the exercise of his art. This much, indeed, may be freely granted, and yet it must at the same time be admitted that the point of view of the physician in relation to this question is necessarily somewhat different from that of the surgeon. It is in the very nature of things that the physician sees more of the natural history of these diseases than the surgeon does. He sees them earlier (he is often blamed for not seeing them early enough) and he sees them later when the surgeon has done his best. The surgeon's interest perhaps tends to slacken when the wound is healed and the patient is so far restored to the *status quo ante*. It then falls to the lot of the physician to watch the slow decay of the vital powers which accompanies the natural progress of the malady and to compare the course of the comparatively few cases which can be, and have been, operated upon with the much greater number of similar cases of disease in which no operation could ever have been possible. From this I think it follows that the physician's outlook on gastric operations, excepting those undertaken for ruptured gastric ulcer, and perhaps, though not certainly, those for simple dilatation of the viscus, is scarcely likely to be so hopeful as that of his surgical brother.

My own interest in the surgical treatment of gastric disease dates from an early period of my professional career. In 1892 I published[2] a paper on the surgical treatment of gastro-intestinal cancer from the point of view of a pathologist and based upon the post mortem examination of 26 consecutive cases. The general conclusion I then arrived at was that the radical cure of gastric cancer by surgical means must always be rare chiefly on account of the great frequency with which secondary extensions undetectable by ordinary means of examination are present, 16 out of 19 cases of gastric cancer presenting on post-mortem examination secondary nodules in the liver or other parts. As the basis of my present study of the subject I have taken the facts recorded in my ward journals since 1895 In this period of eight years I find that there have been under treatment in my wards 220 cases of stomach disease of all kinds, 80 males and 140 females. Of these cases I find that surgical operation was recommended and performed in 23 and it is on a more particular study of the records of these 23 cases (an analysis of which is given below) that I found the remarks I have to make in this paper.

---

Cancer, 6 males, 7 females	13 cases.
Ulcer, all females	4 ,,
Hæmatemesis, all males	2 ,,
Simple dilatation, all males	3 ,,
Stricture of the œsophagus	1 case.
Total	23 cases.

GASTRIC CANCER.

Two methods of surgical treatment suggest themselves both to the physician and the surgeon as applicable to cases of cancer of the stomach: (1) pylorectomy, the radical removal of the tumour itself; and (2) gastro-enterostomy, a palliative procedure for the relief of urgent and distressing symptoms.

1. As regards pylorectomy, I have already referred to my views of the value of this operation as based upon post-mortem room experience. After a somewhat careful consideration of a series of consecutive cases examined post mortem I came clearly to the opinion that in the present state of our diagnosis pylorectomy could seldom be undertaken with any very great prospect of success. In this opinion I found myself in agreement with Guinard. My clinical experience of the last eight years rather strongly confirms me in this opinion. In only one of the 13 cases in which I recommended operation did I advise pylorectomy as the procedure which I [illegible]efully undertaken, and in that case, [illegible] were in every sense most favourable, [illegible] not be completed on account of the highly dangerous collapse of the patient on the operating table The *man recovered from the operation* well and died nearly two months later in my wards from the natural progress of his malady. In all the other cases I advised either an exploratory incision with a view to a possible radical *operation or* the performance of a gastro-enterostomy for the relief of urgent symptoms At this stage it may be right to state the results of the 13 operations for gastric cancer in a tabular form :—

Pylorectomy advised but found to be impossible	1 case (recovery).
Gastro-enterostomy advised but pylorectomy performed as the conditions seemed favourable when the abdomen was opened	2 cases (both died).
Exploratory operation advised and followed by—	
(*a*) Gastro-enterostomy	6 cases (5 recovered).
(*b*) Closing of the wound as nothing could be done	4 cases (3 recovered).

When we examine this table we are struck with one thing—namely, the comparative safety with which an exploratory incision for disease of the stomach can be made. In the whole series of 13 cases there were only four in which the death could be directly attributed to the operation. I regard a death occurring within 48 hours after the operation as probably due to it. Of these four deaths two were cases of pylorectomy, one followed an enterostomy, and one followed the closing of the wound when it was found that nothing could be done. What higher tribute to the success of the surgeon's art could be paid by a physician than such a table as I have given of the results of, perhaps, about the most trying operation to which the human frame could be subjected? Why is it then that pylorectomy for gastric cancer still remains such a fatal operation? I have witnessed the performance of the operation four times and in all the patients died. I cannot answer the question. The surgeon is apt to say that he does not get the cases early enough in the course of the disease and I think there may be a great deal of truth in this statement. But I do not think that it covers the whole ground. It seems to me that the removal of a large portion of the stomach, especially when the organ is the seat of malignant disease, is accompanied by a degree of nervous shock which only a few constitutions are able to recover from. I am well aware of a number of brilliant successes, but I think they are still in the minority. As regards the question of the earliest time at which operation should be recommended I do not think that the physician can do much more than he does at present, unless, indeed, he is prepared to advise every case of chronic dyspepsia to submit to a laparotomy with a possible pylorectomy at the end of it. I for one am not yet prepared to recommend such a course. Our powers of diagnosis in the earliest stages of cancer of the stomach are not yet so perfect as to permit of this. As regards the 13 cases in which I advised operation there was no great difficulty in the diagnosis. In one what was thought to be a dilated gall bladder turned out to be cancer of the stomach and liver. With this exception the diagnosis was clear in all the others. But this leads me to say that when the diagnosis is clear—i.e., when a *tumour is palpable*—the time for pylorectomy or radical operation is past. Here my clinical and my pathological experience agrees. When a gastric cancer is palpable the probability of the presence of secondary extension is very great; and in addition the vitality is likely to be so much reduced that the chances of recovery from a radical operation are very slight. In all such cases while I would not be inclined to advise pylorectomy I would not refuse the patient the slight chance it might afford him if I were quite convinced that he fully appreciated all the risks.

2. I propose now to consider very shortly the operation of gastro-enterostomy or gastro-jejunostomy in the treatment of gastric cancer. From the nature of the disease this operation can only be regarded as a palliative procedure. It is an operation to be recommended in cases where there is marked obstruction of the pylorus, leading *to excessive* pain and vomiting. Possibly the establishment of a gastro-enteric anastomosis might be regarded as likely to retard the growth of a malignant neoplasm of the stomach by preventing the irritation of the tumour by the passage of the gastric contents over its surface, but I think the probability of such a result is too remote to justify the recommendation of the operation on this ground alone. But for purposes of palliation I would not hesitate to recommend it in all suitable cases. In a recent letter to the medical press Mr. A. E. Maylard expressed his doubts as to whether it was right to advise gastro-enterostomy in advanced cases of pyloric cancer when we know that the relief can in the very nature of things only be temporary and when it is almost certain that after a period of marked relief and improvement the patient will have to go through all the suffering and distress again before the final event There is perhaps something to be said in favour of such an attitude, but I confess that I have not very much sympathy with it. It is, I think, the duty *of the physician* and the surgeon alike to afford relief from suffering and to prolong life whenever it is possible to do so and that without consideration of ulterior and it may be inevitable results. Of course, it should always be made clear to the patient that the procedure to be adopted is merely a *temporary* and palliative one.

In our series of 13 cases gastro-enterostomy was performed five times and enterostomy (jejunal fistula) once. In all of these cases—except that of enterostomy, in which the patient died soon after the operation—the relief afforded was most marked and the patients survived the operation for a period of from three weeks to three months, some of them being readmitted to my wards upon the complete healing of the surgical wound. Under the limitations indicated above there can be no doubt that gastro-enterostomy is a most valuable and justifiable procedure in gastric cancer and that the earlier it is *performed*—even before, it may be, the marked emaciation and obstruction have taken place—the more successful is it likely *to* be. As regards the four remaining cases in which merely an exploratory *operation* was possible nothing more need be said. One of the patients died as the result of the *operation*, the others recovered from it and in the *course of time* succumbed to the disease.

In concluding this portion of my paper I may give a statement of the proportion of cases operated upon to the total number of cases of gastric cancer observed in the period dealt with. The *total number* of cases of cancer of the stomach treated was 39—viz., 23 males and 16 females. The total number of operations was 13—viz., 6 *males and* 7 females—i.e., operation was performed in 30 per cent. of the cases treated. In a number of other cases operation was offered but was refused by the patient after a full statement of all the possibilities had been made. The following summaries of these 13 cases are given in chronological order, the male cases first and the female cases second.

Epitome of Cases of Gastric Cancer.

CASE 1.—The patient, a blind man, aged 62 years, was admitted to Ward 7 of the Glasgow Royal Infirmary on Oct. 5th, 1895, complaining of loss of flesh, weakness, and anorexia of six months', and of hiccough and eructation of two months' duration. There was a nodular freely moveable mass palpable in the epigastrium which was decided to be pyloric in situation. No free hydrochloric acid was detected in the gastric contents. Laparotomy was performed on Oct. 25th, but pylorectomy was not proceeded with on account of dangerous collapse. The patient was readmitted, quite recovered from the operation, on Nov. 19th, 1895, and died on Dec. 16th from exhaustion. A post-mortem examination revealed great narrowing and thickening of the pylorus from an epithelioma. No secondary nodules were present. The patient's blindness, which had been present from early youth, was found to be due to quiescent myxomatous tumour in the left lobe of the cerebellum.

CASE 2.—The patient, a man, aged 54 years, was admitted to Ward 7 on March 18th, 1898, on account of pain and vomiting after food of 14 days' duration. His stomach had troubled him since August, 1896, when he had a sudden hæmatemesis. Constipation was troublesome. Cachexia and emaciation were marked. A nodulated palpable tumour could be felt which was judged to be in the greater curvature of the stomach. The patient was transferred to a surgical ward on April 6th. Laparotomy was performed, but the mass could not be removed, nor could gastro-enterostomy be performed. The man recovered from the operation.

CASE 3.—The patient, a man, aged 48 years, was admitted to Ward 7 on April 21st, 1900, on account of vomiting, weakness, and loss of flesh of two months' duration; everything, even water, was vomited. Certainly he was well and strong three months before admission but had been liable to "water-brash" all his life and for some years had suffered from mornic [illegible] he epigastrium wh [illegible] before admission. [illegible] painful and might be situated either in the left lobe of the liver or in the pylorus. There was no vomiting after admission but pain was troublesome in the left hypochondrium. The heart and lungs were normal. Slight albuminuria was present. On April 26th the tumour was diagnosed as gastric in situation. Operation was performed on May 18th. A tumour was found in the left lobe of the liver and another in the posterior wall of the stomach, the latter probably being primary. The wound was closed. The patient was readmitted on June 19th. The wound was perfectly cicatrised and the nodule was still palpable in the epigastrium. The patient died on Sept. 11th from asthenia. A post-mortem examination revealed a large columnar-celled epithelioma of the stomach with secondary nodules in the liver, portal glands, and mediastinal glands.

CASE 4.—The patient, a man, aged 34 years, was admitted to Ward 7 on Jan. 24th, 1902, on acccount of dull epigastric pain of six weeks' duration in consequence of which he had had to lie up three weeks before admission. Pain was not related to taking of food and was not accompanied by vomiting. Constipation was troublesome. The tongue was flabby, indented, and tremulous. On palpation there was fulness in the epigastrium, which was very tender, but no palpable tumour could be made out or succussion. The diagnosis oscillated between disease of the pylorus and disease of the gall-bladder. The heart was normal. Slight albuminuria was present. Operation (performed on Feb 12th) revealed a large malignant tumour in the anterior wall of the stomach with secondary nodules in the liver. The wound was closed. He was readmitted, with the wound healed, on Feb. 25th, and was dismissed to his home at his own request on the 28th.

CASE 5.—The patient, a man, aged 47 years, was admitted to Ward 7 on Jan. 16th, 1903, on account of severe pain in the epigastrium, frequent coffee ground vomiting, and great emaciation (he lost almost three stones in five months), and a mass, obviously pyloric, in the epigastrium. He had been ill for 12 months in all. There was no free hydrochloric acid in the gastric contents. The red blood corpuscles numbered 3,500,000 per cubic millimetre He was transferred to the surgical ward on Feb. 4th and a gastro-enterostomy was performed with great relief to the gastric pain and marked improvement of his general con- [illegible] home on April 13th with [illegible] lower limbs.

[illegible] ged 55 years, was admitted to hospital on July 31st, 1903, on account of pain after food and vomiting of a year's duration. Distinct dilatation of the stomach was present which was treated by lavage, but there was no palpable tumour. No free hydrochloric acid was present. A brother had died from gastric cancer. The patient was transferred to the surgical ward on Sept. 23rd and laparotomy was performed. Diffuse cancerous infiltration of the stomach wall was found. Death ensued in two days.

CASE 7.—The patient, a married woman, aged 40 years, was admitted to Ward 8 on Sept. 3rd, 1898, on account of vomiting and pain in the stomach and of rapidly advancing emaciation of about eight months' duration. She was transferred on Sept. 7th to the surgical ward on account of the constant vomiting. The occurrence of the vomiting immediately after ingestion suggested obstruction near the cardiac end and passage of bougies confirmed this. On the 10th laparotomy was performed and a large tumour was discovered in the stomach. Enterostomy was performed and a duodenal fistula was established. Death ensued within 48 hours. Post mortem examination revealed a large cancerous tumour of the body of the stomach ulcerating into the liver and into the small sac of the omentum.

CASE 8.—The patient, a married woman, aged 27 years, was admitted to Ward 8 on Nov. 23rd, 1898, on account of pain after food and a swelling in the epigastrium. The epigastric tumour was first noticed after a severe attack of pain in the stomach on Nov. 17th, and the history was not that characteristic of gastric cancer. On April 22nd, 1898, she had been admitted on account of chronic gastric catarrh with doubtful evidence of ulceration in the form of an obscure history of coffee-ground vomiting. She remained well till August, 1898, when another attack of pain and vomiting occurred, the vomited matter being brown in colour and in quantity about a cupful. She had similar attacks in the middle of August and in October. Since then she had suffered from constipation and a tendency to melæna. She was transferred to the surgical ward on Nov. 27th, with the view that the epigastric tumour might possibly be an abscess connected with an ulcer of the stomach. On the 29th laparotomy was performed, when a large cancerous tumour involving the pylorus with widespread implication of the neighbouring glands was discovered. Removal was impossible but gastro enterostomy was performed. She recovered well from the operation and had temporary relief from her pain.

CASE 9.—The patient, a married woman, aged 54 years, was admitted on Sept. 9th, 1899, to Ward 8 on account of progressive weakness and emaciation of a year's duration and of very constant vomiting after food of six or eight months' duration. A large, very hard, painless, freely moveable, and nodulated tumour (first noticed by the patient in the previous March), evidently involving the pylorus and the greater curvature of the stomach, was easily palpable. For the relief of the vomiting she was transferred to the surgical ward on Sept. 19th, where gastro-enterostomy was performed, with immediate relief of the vomiting. The patient died from asthenia on Oct. 11th and a post mortem examination held on the 13th revealed a perfectly formed artificial pylorus, as well as a large epithelioma of the pylorus, extending towards the cardiac end and also towards the opening into the jejunum. Secondary tumours were found in the left lung and pleura but none in the liver.

CASE 10.—The patient, a married woman, aged 55 years, was admitted on Sept. 27th, 1901, to Ward 8, on account of vomiting of food occasionally for four years and of loss of flesh of one month's duration. A hard mass, evidently pyloric in situation, could be felt in the epigastrium and striking gastric peristalsis was visible. Vomiting and constipation had persisted for four years. Two years previously an attack of severe pain in the stomach had occurred, followed on the next day by hæmatemesis (coffee ground) and tarry motions; ulcer was then diagnosed. The hæmatemesis was not repeated but for two years she had vomited two or three times a week, the ejecta appearing to be greater means must always be rare chiefly on account of the great frequency with which secondary extensions undetectable by ordinary means of examination are present, 16 out of 19 cases of gastric cancer presenting on post-mortem examination secondary nodules in the liver or other parts. As the basis of my present study of the subject I have taken the facts recorded in my ward journals since 1895 In this period of eight years I find that there have been under treatment in my wards 220 cases of stomach disease of all kinds, 80 males and 140 females. Of these cases I find that surgical operation was recommended and performed in 23 and it is on a more particular study of the records of these 23 cases (an analysis of which is given below) that I found the remarks I have to make in this paper.

Cancer, 6 males, 7 females	13 cases.
Ulcer, all females	4 „
Hæmatemesis, all males	2 „
Simple dilatation, all males	3 „
Stricture of the œsophagus	1 case.
Total	23 cases.

GASTRIC CANCER.

Two methods of surgical treatment suggest themselves both to the physician and the surgeon as applicable to cases of cancer of the stomach: (1) pylorectomy, the radical removal of the tumour itself; and (2) gastro-enterostomy, a palliative procedure for the relief of urgent and distressing symptoms.

1. As regards pylorectomy, I have already referred to my views of the value of this operation as based upon post-mortem room experience. After a somewhat careful consideration of a series of consecutive cases examined post mortem I came clearly to the opinion that in the present state of our diagnosis pylorectomy could seldom be undertaken with any very great prospect of success. In this opinion I found myself in agreement with Guinard. My clinical experience of the last eight years rather strongly confirms me in this opinion. In only one of the 13 cases in which I recommended operation did I advise pylorectomy as the procedure which I thought might be hopefully undertaken, and in that case, though the conditions were in every sense most favourable, the operation could not be completed on account of the highly dangerous collapse of the patient on the operating table The man recovered from the operation well and died nearly two months later in my wards from the natural progress of his malady. In all the other cases I advised either an exploratory incision with a view to a possible radical operation or the performance of a gastro-enterostomy for the relief of urgent symptoms. At this stage it may be right to state the results of the 13 operations for gastric cancer in a tabular form :—

Pylorectomy advised but found to be impossible	1 case (recovery).
Gastro-enterostomy advised but pylorectomy performed as the conditions seemed favourable when the abdomen was opened	2 cases (both died).
Exploratory operation advised and followed by—	
(a) Gastro-enterostomy	6 cases (5 recovered).
(b) Closing of the wound as nothing could be done	4 cases (3 recovered).

When we examine this table we are struck with one thing—namely, the comparative safety with which an exploratory incision for disease of the stomach can be made. In the whole series of 13 cases there were only four in which the death could be directly attributed to the operation. I regard a death occurring within 48 hours after the operation as probably due to it. Of these four deaths two were cases of pylorectomy, one followed an enterostomy, and one followed the closing of the wound when it was found that nothing could be done. What higher tribute to the success of the surgeon's art could be paid by a physician than such a table as I have given of the results of, perhaps, about the most trying operation to which the human frame could be subjected? Why is it then that pylorectomy for gastric cancer still remains such a fatal operation? I have witnessed the performance of the operation four times and in all the patients died. I cannot answer the question. The surgeon is apt to say that he does not get the cases early enough in the course of the disease and I think there may be a great deal of truth in this statement. But I do not think that it covers the whole ground. It seems to me that the removal of a large portion of the stomach, especially when the organ is the seat of malignant disease, is accompanied by a degree of nervous shock which only a few constitutions are able to recover from. I am well aware of a number of brilliant successes, but I think they are still in the minority. As regards the question of the earliest time at which operation should be recommended I do not think that the physician can do much more than he does at present, unless, indeed, he is prepared to advise every case of chronic dyspepsia to submit to a laparotomy with a possible pylorectomy at the end of it. I for one am not yet prepared to recommend such a course. Our powers of diagnosis in the earliest stages of cancer of the stomach are not yet so perfect as to permit of this. As regards the 13 cases in which I advised operation there was no great difficulty in the diagnosis. In one what was thought to be a dilated gall bladder turned out to be cancer of the stomach and liver. With this exception the diagnosis was clear in all the others. But this leads me to say that when the diagnosis is clear—i.e., when a tumour is palpable—the time for pylorectomy or radical operation is past. Here my clinical and my pathological experience agrees. When a gastric cancer is palpable the probability of the presence of secondary extension is very great; and in addition the vitality is likely to be so much reduced that the chances of recovery from a radical operation are very slight. In all such cases while I would not be inclined to advise pylorectomy I would not refuse the patient the slight chance it might afford him if I were quite convinced that he fully appreciated all the risks.

2. I propose now to consider very shortly the operation of gastro-enterostomy or gastro-jejunostomy in the treatment of gastric cancer. From the nature of the disease this operation can only be regarded as a palliative procedure. It is an operation to be recommended in cases where there is marked obstruction of the pylorus, leading to excessive pain and vomiting. Possibly the establishment of a gastro enteric anastomosis might be regarded as likely to retard the growth of a malignant neoplasm of the stomach by preventing the irritation of the tumour by the passage of the gastric contents over its surface, but I think the probability of such a result is too remote to justify the recommendation of the operation on this ground alone. But for purposes of palliation I would not hesitate to recommend it in all suitable cases. In a recent letter to the medical press Mr. A. E. Maylard expressed his doubts as to whether it was right to advise gastro-enterostomy in advanced cases of pyloric cancer when we know that the relief can in the very nature of things only be temporary and when it is almost certain that after a period of marked relief and improvement the patient will have to go through all the suffering and distress again before the final event There is perhaps something to be said in favour of such an attitude, but I confess that I have not very much sympathy with it. It is, I think, the duty of the physician and the surgeon alike to afford relief from suffering and to prolong life whenever it is possible to do so and that without consideration of ulterior and it may be inevitable results. Of course, it should always be made clear to the patient that the procedure to be adopted is merely a temporary and palliative one.

In our series of 13 cases gastro-enterostomy was performed five times and enterostomy (jejunal fistula) once. In all of these cases—except that of enterostomy, in which the patient died soon after the operation—the relief afforded was most marked and the patients survived the operation for a period of from three weeks to three months, some of them being readmitted to my wards upon the complete healing of the surgical wound. Under the limitations indicated above there can be no doubt that gastro-enterostomy is a most valuable and justifiable procedure in gastric cancer and that the earlier it is performed—even before, it may be, the marked emaciation and obstruction have taken place—the more successful is it likely to be. As regards the four remaining cases in which merely an exploratory operation was possible nothing more need be said. One of the patients died as the result of the operation, the others recovered from it and in the course of time succumbed to the disease.

In concluding this portion of my paper I may give a statement of the proportion of cases operated upon to the total number of cases of gastric cancer observed in the period dealt with. The total number of cases of cancer of the stomach treated was 39—viz., 23 males and 16 females. The total number of operations was 13—viz., 6 males and 7 females—i.e., operation was performed in 30 per cent. of the ward at 3 A.M., complaining of pain in the abdomen of eight hours' duration. For two months before this she had been complaining of pain in the stomach setting in from half an hour to an hour after food but there had been no vomiting before the day of admission. On the day before admission, about 7 P.M., she was suddenly seized with severe pain in the abdomen, accompanied by pale lividity of the countenance. A medical man who was called ordered fomentations. He was summoned again and found her doubled up with pain, the knees being drawn up on the abdomen. He ordered her removal to the infirmary. At the time of admission she was on the whole better; the pulse numbered 100 and was small, the temperature was 99° F., and she vomited a little bile only on one occasion. Dr. Hunter saw her at 12 noon on the 4th and advised immediate operation. On opening the abdomen bile-stained fluid was found in the peritoneal cavity as well as a perforation in the stomach wall large enough to admit a goose-quill and situated on the anterior surface one and a half inches above the great curvature and slightly to the left of the middle line. The rupture was sutured. A post-mortem examination verified the state of matters found on operation.

CASE 4.—The patient, a female, aged 25 years, single, was admitted to Ward 8 on Sept. 6th, 1900, under the care of Dr. Hunter, and transferred to the surgical ward for operation on the 7th. She had suffered from dyspepsia for eight years and had been under treatment before admission since Sept. 4th for peritonitis. On opening the abdomen a ruptured ulcer and a localised peritonitis were discovered. The post-mortem summary was in the the following terms: "Gastric ulcer; rupture of stomach; ulcer sutured."

The foregoing list, unsuccessful as the cases were, is not without important lessons. In the surgical treatment of ruptured gastric ulcer time is a factor of the very highest moment. The earlier a rupture is recognised and operation undertaken the better the results of the operation are likely to be. In this connexion I may refer to two cases which I recorded in the *Glasgow Medical Journal* in 1899 and in which the precise time from the occurrence of the perforation to the development of a fatal general peritonitis could be estimated with probable accuracy. In one, a case of duodenal ulcer, death occurred 21 hours, and in the other, a case of gastric ulcer, 25 hours after the occurrence of perforation. In neither case was an operation performed. In both the actual time of perforation could be accurately fixed and in both a most intense general peritonitis, with escape of the gastric contents into the cavity of the peritoneum, was discovered on post-mortem examination. Of course the situation of the perforation varies in different cases. In some the perforation may be so situated that only a localised peritonitis with subsequent abscess formation may result. In others the rupture may lead to the escape of the contents of the stomach directly into the cavity of the peritoneum, as in the two cases to which I have just referred. In the former class of case we may perhaps, and sometimes possibly with advantage, be able to wait and watch before resorting to surgical interference; but in the latter class we must advise operation at the very earliest moment if we are to have any chance of saving the life of the patient. In either class of case, however, the clinical skill and acumen of the physician will be taxed to the uttermost.

Before concluding this section of my paper I should like briefly to refer to two methods of diagnosis which have been much practised in dealing with cases of ruptured gastric ulcer. *First, with regard to the area of hepatic dulness*, it has been pointed out by a number of observers that in many cases of rupture of the stomach the area of hepatic dulness rapidly disappears. In the first of our list of cases the hepatic area was found to be greatly diminished in size and this formed one of the factors which led to our advising an operation. As we have seen, no ulcer was found in the case and the patient recovered well. Personally I do not think that we can place much reliance upon this physical sign and I would refer you to a communication by my former house physician, Dr. W. G. Rodger, in which he gives the results of his investigations on this matter in six cases, five of which were from my wards and one from the wards of my colleague, Dr. J. W. Allan.[3] *Secondly, with regard to leucocytosis*, I am inclined to think that the development of a rapid leucocytosis would be a valuable indication in our efforts at diagnosis and I think a blood count should be made in all cases. The leucocytosis may not indicate a general peritonitis but its presence would probably point to pus formation and so it may be a valuable guide as to whether operation should be undertaken or not. In one of the cases reported by Dr. Rodger where there was a duodenal ulcer perforating the pancreas but without causing peritonitis the leucocyte count rose from 5250 at 2 A.M. to 25,600 per cubic millimetre at 9 A.M.

HÆMATEMESIS.

There is perhaps no affection of the stomach the treatment of which causes the physician more anxiety than that which is accompanied by copious vomiting of blood. Hæmatemesis due to gastric disease may be of two kinds: it may be due (1) to a more or less continuous oozing from a simple or malignant ulcerated surface, in which case the vomited matter is usually of the "coffee-ground" character, or it may be caused (2) by the perforation of a comparatively large branch of one of the gastric arteries, in which case the blood vomited may be quite fluid or in the form of bright red clots. (With the copious hæmorrhage which sometimes complicates hepatic cirrhosis or is caused by varix of the œsophagus we are not at present concerned.) In cases of hæmatemesis due to arterial perforation copious tarry motions are common and in some almost as much blood may pass down into the intestine as is evacuated by the mouth. Such severe hæmorrhage may occur during the progress of a simple perforating ulcer or more rarely as the result of a "pore-like" erosion of the wall of one of the larger branches of the gastric arteries (exulceratio simplex of Dieulafoy[4]) without any marked ulceration of the surrounding mucous membrane and at most accompanied by an abrasion so slight in area and degree that the lesion might readily enough be overlooked even at the necropsy. Very severe hæmorrhages occurring in the course of Cruveilhier's perforating ulcer are not infrequently quite recovered from under ordinary medicinal treatment but the chance of recovery in a well-marked case of "pore-like" erosion of the gastric arteries is, I should think, very slight unless, indeed, the surgeon can ligature the bleeding point. Fenwick divides hæmorrhage from chronic ulcer of the stomach into three varieties: (1) slight hæmorrhage; (2) moderate hæmorrhage; and (3) excessive hæmorrhage (l'hémorragie foudroyante). Now in cases of "pore-like" erosion the bleeding is usually of the "foudroyante" variety and this variety of bleeding, according to the same authority, is rare, being only observed in 3·4 per cent. of the cases examined.[5] In some of such cases the source of the hæmorrhage may be, and I think probably has been, overlooked even on the post-mortem table and the bleeding has been erroneously ascribed to congestion and diapedesis. I have met with two such cases, confirmed by necropsy, which I have already published.[6] In one of the cases the hæmorrhage might be described as severe if not excessive and in the other as "foudroyante." The first died exhausted from a diarrhœa which set in after the hæmorrhage had been arrested and the second died on the fourth day of residence, during which he had vomited 96 ounces of blood in addition to profuse tarry motions, and exclusive of a profuse hæmatemesis before admission which had caused him to fall fainting in the street, and which an ambulance attendant who picked him up and brought him to the infirmary estimated at from two to three pints. In this case I asked my colleague Mr. J. Hogarth Pringle to open the stomach after all available medicinal means had failed but he was unable to find the source of the bleeding.

In "pore-like" erosion of the gastric arteries an important point in the diagnosis is the absolute suddenness with which in many cases the hæmorrhage sets in, and often without any previous history of gastric disorder. In one of the two cases noted above the attack came on in the midst of apparent health, and in the other the longest clinical history of stomach symptoms that could be obtained was one of four weeks. I believe, however, that I have seen a third case which was more striking than either of these two but in which the diagnosis could not be confirmed by post-mortem examination. The patient was a robust stout man of middle age, whom I saw on May 1st, 1901, in consultation with his medical man, Dr. J. N. Glaister of Glasgow. On the morning of that day in the midst of good health and the active discharge of his daily duties, and without any clinical history of previous gastric disturbance except an occasional attack of dyspepsia, he was suddenly seized after a hearty breakfast with a profuse hæmatemesis. This had continued all day in spite of careful treatment and I was called to see him at midnight. I found him exsanguine and collapsed, and with a bowlful of bright red blood at his bedside which he had just vomited. Nothing further could be done and he died early the next day. I have no doubt in my own mind that this was a case of "pore-like" erosion or "exulceratio simplex" of Dieulafoy.

[6] p. [illegible]

Now, in all cases of severe hæmatemesis due to organic disease of the stomach, whether caused by simple ulcer or by "pore-like" erosion, I am of opinion that the propriety of calling in surgical help should from the first be carefully considered by the physician, particularly if profuse bleeding is repeated at short intervals and the life of the patient is threatened from collapse. In cases where there is a clear history of chronic ulcer I think medical treatment may be pursued for a time with fair prospects of success in many even severe cases, but in cases of "pore-like" erosion where the "foudroyante" type of bleeding starts with appalling suddenness *the sooner the surgeon is called the better.* Dieulafoy has recorded one brilliant success, the life of a patient threatened by profuse hæmorrhage from "exulceratio simplex" being saved by immediate operation; and such records are always encouraging. In severe hæmorrhage from simple ulcer the operation should be easier as the site of the ulcer would serve as a guide to the bleeding point, but in "pore-like" erosion it may be exceedingly difficult to find the bleeding point after the stomach is opened. Nevertheless, the attempt should be made. In the case of ulcer, too, the presence of deep-seated adhesions or the situation of the ulcer may give rise to difficulties not easy to overcome. In spite of it all, however, our only hope in many of these cases is in the surgeon.

Epitome of Cases of Hæmatemesis.

CASE 1. *Severe hæmatemesis from a simple ulcer of the stomach, in which the stomach was opened and the edges of the ulcer were brought together by sutures.*—The patient was a man, aged 46 years, who had been suffering from anorexia, pain after food, and frequent vomiting for five months before admission. He had had three separate attacks of severe hæmatemesis—the first in July, 1899, the third on Oct. 1st of the same year, the day before his admission to the infirmary. He was very weak and greatly emaciated. As he was very willing to have something done which might prevent the recurrence of the bleeding he was transferred to the surgical ward on Oct. 5th. I was of opinion that the bleeding was from an ulcer and not from a "pore-like" erosion. After his transference the bleeding ceased and nothing was done. On the 15th it recurred with great severity. I saw him in the evening in consultation with Mr. James Luke, who was acting for my colleague Mr. Pringle and we agreed that operation should be performed at once. A simple ulcer was found, the wall at the site of the ulcer being adherent to the liver; its edges were brought together by sutures after the surface had been scraped by a Volkmann's spoon. The patient recovered from the chloroform but died a few hours afterwards from exhaustion.

CASE 2.—This was a case of profuse hæmatemesis due to "pore-like" erosion of a branch of the left gastro-epiploic artery. Laparotomy and exploration of the interior of the stomach were performed by Mr. Pringle. 96 ounces of blood were vomited during four days' residence. Profuse tarry motions were passed. Death occurred one and a half hours after operation. This case has been sufficiently referred to above and has already been published in detail.[7]

DILATATION OF THE STOMACH.

There is, perhaps, no affection of the stomach which in well-selected cases may be more successfully treated by the surgeon than that of simple dilatation of the organ. I mean by this dilatation which is produced by other causes than by malignant disease. As we have already seen, even in dilatation due to malignant disease, the operation of gastro-enterostomy may afford great temporary relief from severe suffering, but in the affections with which I am now dealing, we may, in certain cases, hope for much more permanent benefit if not for absolute cure.

Simple dilatation of the stomach may arise, I think, in several different ways. It may be caused by the cicatricial contraction of the pylorus arising from the healing of a simple ulcer at or in the immediate neighbourhood of the orifice. It may be caused by peritoneal adhesions binding the pylorus to the under surface of the liver in the region of the gall-bladder. Or it may arise from an atonic relaxation of the coats of the stomach the result of chronic catarrh due to long-continued errors of diet and overloading of the viscus. In such cases there may be no actual narrowing of the pylorus itself. In a few cases the dilatation may be due to what can only be regarded as a congenital narrowing of the pyloric opening. Now in all such cases when medical treatment has been fairly tried and has failed, we may with the greatest confidence appeal to the surgeon for help. It is always right that medical and dietetic treatment should be given a thorough trial before resorting to operation, because it must be admitted that in a certain number of cases, more especially those which are of the atonic variety and due to errors of diet, a cure may be effected by such treatment. A cure by medical means must always be preferable, for, however successful the operation, there must ever be the risk of a cicatrix yielding and giving rise to hernia, or of obstructive complications arising from the dislocation of normal relationships which is necessarily involved in any surgical procedure. There is also, I think, some danger of the artificial opening contracting somewhat in the course of time, but this is not so likely to happen in cases where there is a decided stenosis of the pylorus. There can be little doubt that gastro enterostomy is the operation to be preferred in all such cases, and when medicine has entirely failed surgery must be resorted to. My experience of this method of treatment is limited to four cases, three in hospital and one in private practice, and in all the results were most satisfactory.

Epitome of Cases of Dilatation of the Stomach.

CASE 1.—The patient, a man, aged 30 years, was admitted to Ward 7 for the first time on May 22nd, 1899, and was dismissed very greatly improved about two months later, on July 25th. On admission he was suffering from dilatation of the stomach and hæmorrhage into its cavity and into the intestinal canal. Except for well-marked Hippocratic succussion and a slight enlargement of the left lobe of the liver physical examination gave negative results. The washings of the stomach contained altered blood and anæmia was very profound. On May 29th the hæmoglobin was 20 per cent. and red blood corpuscles numbered 1,380,000 per cubic millimetre. The evening temperature often reached 101° or 102° F. The heart and lungs were normal. The illness dated from Jan. 1st, and was characterised by pain in the epigastrium and beneath the left shoulder after food, by frequent vomiting, and by progressive weakness, so that he had been quite unable to work since March. He was treated by rest, rectal feeding, and lavage of the stomach. At the time of dismissal he was very well. The hæmoglobin was 60 per cent. and the red blood corpuscles numbered 4,560,000 per cubic millimetre. The patient was readmitted to Ward 12 on May 6th, 1901, and transferred to the surgical ward on June 10th when gastro-enterostomy was performed on the 13th by Mr. Pringle. After his previous residence he had remained very well till March, 1901, when as the result of a chill his gastric symptoms again became very urgent. Succussion revealed very great dilatation and constipation was extreme The operation was very successful. He made an uninterrupted recovery and left the infirmary on August 2nd, 1901, quite well Several attempts have been made to find him at various addresses since then but have failed.

CASE 2.—The patient, a man, aged 40 years, was admitted to Ward 7 for the first time on Dec. 22nd, 1900, and dismissed, on account of family reasons, on Jan. 5th, 1901, greatly improved. On this occasion he was suffering from subacute gastric catarrh with considerable dilatation of the stomach, the symptoms having been present for about 13 weeks and consisting chiefly of pain in the epigastrium followed by vomiting. Except for moderate dilatation no evidence of serious organic disease could be detected. The heart and lungs were normal and the urine, at first slightly albuminous, soon presented healthy characters. The patient was readmitted on April 28th, 1902, *with all the signs and symptoms of great atonic dilatation of the stomach. No* tumour could be detected and there was no specially painful area. He was transferred to the surgical ward on May 19th and the operation of gastro-enterostomy was successfully performed by Mr. Pringle. The following letter from his medical attendant (Dr. J. W. Little of Newmains) shows his condition at the present time: "I have been asked by Mr. —— to reply to your letter of Feb. 9th and state that he has enjoyed quite exceptional health since the operation, never having missed his daily work since, nor has he had any stomach symptoms and can take all kinds of food with impunity. He also intends to visit you at the infirmary on Saturday between 9 and 11 o'clock." I saw the patient on Feb. 13th, 1904, and found him in all respects perfectly well and the cicatrix firm and strong.

---

[7] Transactions of the Medico-Chirurgical Society of Glasgow, 1900, vol. ii., p. 242; also Author's Lectures on Clinical Medicine, Glasgow, 1900, p. 180.

CASE 3.—The patient, a man, aged 40 years, a miner, was recently readmitted for the second time to Ward 7 on Dec. 12th, 1903, on account of vomiting after food and general nervous debility. He was dismissed towards the end of January, 1904, having maintained fair health and a good appetite, except for a few days when he had some vomiting. The following summary of the rather extensive clinical notes is all that need be given here. Gastro-enterostomy was performed in June, 1902, on account of dilatation of the stomach, associated with vomiting, nervousness, and debility of at least three years' duration. He had been in previous residence from Jan. 27th to March 18th, 1899. He was then suffering chiefly from catarrh of the stomach. After leaving the hospital he was treated as an out-patient of the wards for stomach symptoms, with gradually advancing dilatation, till June, 1902, when he was readmitted for the purpose of having gastro-enterostomy performed. Since then, although enjoying fair health on the whole, he has been liable to occasional attacks of vomiting, the last severe attack having occurred in November, 1903. The result in this case has not been so good as in the other two cases, but this may partly be accounted for by the fact that his nervous system has been weakened by a severe crushing accident six or seven years ago which has permanently crippled his right leg and prevented him following his ordinary occupation.

The last of the 23 operations on the stomach which have formed the basis of this paper—viz., gastrostomy for cancerous stricture of the œsophagus—need not be considered in detail, as the disease does not involve the stomach and so hardly comes within the scope of my present subject.

In what has gone before I think I have clearly shown that, with careful selection, there are many affections of the stomach which may be most beneficially and successfully treated by surgical operation. As regards malignant disease I fear that in the meantime at least the results of surgical interference will be mainly palliative. In cases of ruptured ulcer, of excessive hæmatemesis and of dilatation we may in many cases confidently expect, not only the immediate saving of life, but a permanent cure of the malady as the result of operation. To my surgical colleagues, Mr. J. Hogarth Pringle, F.R.C.S. Eng., by whom the majority of the operations here recorded were performed, and Mr. Luke, who acted in his chief's absence, I must, in conclusion, express my gratitude, not only for the great skill which they displayed in the performance of these delicate and difficult surgical procedures, but also for the invaluable help which they so readily afforded me in the preceding study and examination of the cases for purposes of diagnosis.

Glasgow.

FIVE CASES OF CARCINOMA OF THE MALE BREAST.

BY CHARLES R. KEYSER, F.R.C.S. ENG.,
SURGICAL REGISTRAR TO THE CANCER HOSPITAL.

CANCER of the male breast is so rare a disease that there is no necessity to offer an excuse for recording the following cases. Over 14 years ago Roger Williams[1] published a paper on 100 cases of cancer of the male breast and since then only a few isolated cases have from time to time been recorded. Thus Shattock[2] described one in a man, aged 57 years, who had noticed a growth in the breast for three years. This patient also had a yellowish discharge from the nipple. Microscopically the tumour was a duct carcinoma. This case is of especial interest as duct carcinoma occurring in the male breast is exceedingly rare. Wagstaffe[3] quotes a case of a man, aged 61 years, who had carcinoma of both breasts and published a report of 20 cases which were observed between 1857 and 1875. Lunn[4] recorded a most interesting example occurring in a man, aged 91 years, who had suffered pain in the left breast for ten months before admission into the Marylebone Infirmary. For three months a lump had been noticed in the axilla. A fungating growth was present in the left breast involving the nipple and an area of one inch around the nipple. The growth was moveable on the deeper parts but a gland was felt in the axilla. The breast and the glands were removed but the patient died a few days afterwards from hypostatic congestion of the lungs. The growth was reported to be a duct carcinoma, notwithstanding the presence of the glands in the axilla. This patient is said to be the oldest on record suffering from cancer of the breast. Warfield[5] collected 37 cases which occurred between 1890 and 1901 but this includes some of those already recorded. W. Blair Bell[6] has recently published a case of a man, aged 56 years, who four and a half years previously noticed a small, hard lump, of the size of a pea, in the right breast. This gradually increased in size and two and a half years after the tumour was first noticed it began to ulcerate. There was never any discharge from the nipple. The right breast presented an ulcer, four inches by three inches, the edges of which were hard, raised, and everted. There was a foul discharge and the ulcer bled easily. No glands were felt. The breast and the underlying fascia and muscle were removed as well as glands which were found in the axilla. The growth recurred 15 months after the operation in the skin above the scar; a deposit was also felt on the fifth left rib. Both of these were removed but the patient died one year and nine months after the first operation.

The Museum of the Royal College of Surgeons of England contains six specimens of cancer of the male breast; in five in which the age and the duration of the growth are stated the average is 57 and four and a half years respectively. The Museum of St. George's Hospital contains five specimens, in two of which the histories of the patients are given. In the first of these the growth was removed from a man, aged 58 years, who noticed a small lump in the right breast four years previously to admission to the hospital. A slight bloody discharge from the nipple had also been observed. Since then the growth had slowly but steadily increased in size and occasionally had been painful. On examination a hard nodular tumour of the size of an orange was felt close to the nipple; it was adherent to the skin but freely moveable on the deeper parts. The skin was discoloured and the nipple was retracted; a gland could be felt in the axilla. The breast was removed. It was reported that the patient's father had died at the age of 80 years from the same complaint, the tumour having existed for 13 years. The second specimen was removed from a man, aged 64 years, who had perceived a swelling of the right breast gradually increasing in size for a period of eight years. At the time of operation the tumour was of about the size of a large walnut; it was adherent to the skin but moveable on the pectoral muscle. There were no glands to be felt in the axilla. The growth was said to have been caused by a blow from a stone.

From recent reports from three of the large London hospitals I have collected 1416 cases of carcinoma of the breast; only ten of these occurred in males, or 1 in 140·5. Warfield says that in three years 307 cases of carcinoma of the breast were treated at the Johns Hopkins Hospital; three of these were in males. Roger Williams states that of all the neoplasms of the breast about 1 per cent. occur in males. The same authority gives 50 years as the average age at which the disease commences; in nine cases which I have collected the average age was 61·5 years.

The histories of the five hitherto unpublished cases which form the subject of this paper are as follows.

CASE 1.—The patient, a man, aged 61 years (Fig. 1), was admitted into the Cancer Hospital, under the care of Dr. F. A. Purcell, on April 23rd, 1895. Two years before, whilst lifting a heavy box, he was struck by a corner of it on the right breast. The breast was bruised and became very tender. Soon afterwards a hard lump "like a button" was found under the nipple; this increased in size and 12 months later it began to discharge. On examination a large, hard, raised mass was found which was ulcerated on the surface and tender to the touch. No remains of the nipple could be seen. The tumour was slightly moveable on the deeper tissues. The glands all matted together were felt in the axilla. The right side of the heart was dilated and emphysema was present. On April 27th the breast and the glands were removed but the patient died on May 12th.

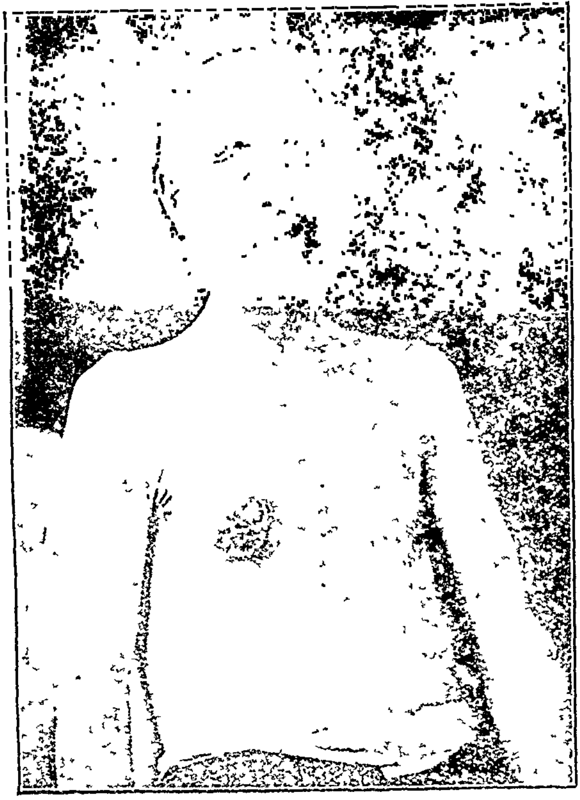
FIG. 1.



Ulcerating cancer of the breast.

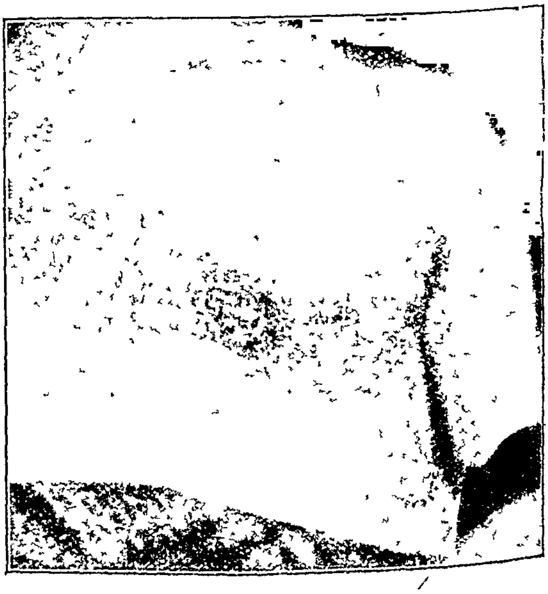
CASE 2.—The patient, a man, aged 48 years, was admitted into the Cancer Hospital on Nov. 11th, 1897, under the care of Dr. Purcell. 12 months previously he noticed pain and itching about the right nipple. There was no history of injury. On examination, just to the outer side of the right nipple was a hard, freely moveable lump, of the size of a small walnut. The skin was adherent but the nipple was not retracted. There was no discharge from the nipple. On the 13th the tumour was excised but the axilla was not opened. The patient made an excellent recovery and was discharged on Dec. 1st. He returned on March 7th, 1902, and stated that for two years he had noticed a small lump in the right axilla and that for one year there had been a small growth in the scar. Both were gradually increasing in size and caused some shooting pain. There were present a small moveable tumour of the size of a hazel nut in the scar, which was not attached to the skin, and a large, moveable mass close to the axilla. Both were removed. After leaving the hospital the patient was lost sight of.

CASE 3.—The patient, a man, aged 63 years, was admitted into the Cancer Hospital on Jan 9th, 1899, under the care of Dr. Purcell. The history was that three years previously he had injured the right breast and that one year previously he had noticed that the right breast was harder than the left. He never suffered any pain. On examination the right breast was larger than the left and a hard, circular mass about two inches in diameter could be felt just beneath the nipple which was depressed. The mass was adherent to the skin but was moveable on the deeper parts. No glands were felt in the axilla. On the 11th the growth was freely excised. An excellent recovery followed and the patient was discharged from hospital on the 23rd.

CASE 4.—The patient, a man, aged 48 years, was admitted into Charing Cross Hospital on May 19th, 1899, under the care of Mr. H. F. Waterhouse. 12 months previously he injured the right breast so as to cause bruising. Three months before he noticed that the breast was getting hard and that at times there was a discharge of blood from the nipple. He never suffered any pain. On examination the patient was very fat and looked older than his age. There was a marked prominence of the right nipple and a tumour, purple in colour, of the size of a five-shilling piece, could be seen just below and to the inner side of the nipple. On palpation a large hard mass, rounded in shape and of the size of a small orange, could be felt. The skin was adherent but the tumour was moveable on the pectoral muscle. No glands were felt in the axilla. On May 25th the breast was amputated by an elliptical incision and the axilla was cleared out; many glands were found in the latter situation. After leaving the hospital the patient was next seen in January, 1900, when he was quite strong and well and showed no sign of recurrence. In April, 1904, he returned to the hospital with facial paralysis and signs of bulbar paralysis and died on May 1st.

CASE 5.—The patient, a man, aged 62 years (Fig. 2), was admitted into the Cancer Hospital on Oct. 12th, 1903, under the care of Mr. F. B. Jessett. 18 months ago a "boil" appeared on the left side of the chest and another one 16 months later. Five weeks ago the present sore was noticed and it "broke" three weeks afterwards. On the inner side of the left nipple there was a raised, indurated, dusky patch three inches in diameter, the upper part of which was sloughy and was discharging pus. On the 23rd the mass was scraped and swabbed with pure carbolic acid Microscopically the ulcer was an epithelioma. It was also of some interest to learn that the patient's son was in the hospital at the same time for cancer of the tongue.

FIG. 2.



Epithelioma of the left breast.

The diagnosis of all these five cases was verified after operation by the microscope and in no instance was there any doubt as to the nature of the growth. Cases 1, 2, and 3 were examples of the ordinary scirrhus cancer, Case 4 was a soft spheroidal-celled carcinoma, and Case 5 was a squamous-celled epithelioma. The last case is particularly interesting owing to its extreme rarity. Roger Williams recorded three cases and quotes one case which Czerny described. The following case is of interest although not an example of malignant disease.

A man, aged 44 years, was admitted into the Cancer Hospital on April 7th, 1897, under the care of Mr. Cotterell. The history was that two years previously he had received a bite from a horse on the left breast and that two months previously he noticed a swelling of the left breast which gave him much pain, especially on pressure. On examination the left breast seemed to be in a condition of simple hypertrophy; there was no defined edge to the swelling which was diffused over the whole area of the breast. The nipple was not prominent and there was no [illegible] breast was amputated as [illegible]. Histologically the growth [illegible] patient returned to the hospital on July 1st, 1899, with a second fibro-adenoma in the right breast.

Most text-books on surgery dismiss the subject of cancer of the male breast very briefly and Sheild,[7] although discussing the disease at greater length, says that "the symptoms and course are precisely similar to what is found in females." From a study of all the cases with which I am acquainted some facts may be deduced which show that the disease in men does not follow quite the same course as it does in women. The differences may be of minor importance but [illegible] may be arranged under the [illegible] (2) side affected; (3) durati[illegible]; [illegible]

1. *Age.*—The age at which the disease occurs varies from 12 to 91 years. In nine cases which I have collected the [illegible]; this is somewhat higher than [illegible] he gives 50 years as the mean. [illegible] partly to the fact that I have only taken the average of a very small number of cases and partly because in my series Lunn's case is included, the age of his patient being 91 years. At all events, the average age at which the disease occurs in men is many years later than in women; in the latter Sheild says it is most common between 40 and 60 years. Quite recently Leaf,[8] who has investigated 100 cases of cancer of the breast in women, found that the average age at which the disease commences is 49 years two months. Bland Sutton[9] says it is most common between 40 and 50 years; Watson Cheyne[10] between 35 and 60 years; and Pick[11] between 35 and 55 years. Moreover, a relatively large number of the cases in men commence over the age of 70 years or between 60 and 70 years (Warfield).

2. *Side of the body affected.*—In women carcinoma of the breast is more often found on the left side, whereas the opposite is the case in men. Out of 31 cases quoted by Wagstaffe 16 had the right breast affected and 12 the left; in three instances both sides were diseased. Since the publication of these I have collected 11 cases and of this series the right breast was implicated eight times and the left three, showing that the disease occurs nearly three times as frequently on the right as on the left side.

3. *Duration.*—In 13 cases the length of time that the growth had been noticed by the patient is mentioned; ten years is the longest and three months is the shortest, the mean being 3·36 years. (R. Williams gives 3·16 years.) In women the average duration is somewhat less than this. I am unable to give the total duration of life as in most of the cases it is not recorded, but Warfield mentions one case where the patient lived 35 years. In Wagstaffe's paper the duration of life is given in 30 cases: 11 lived under one year, eight rather more than one year, one over two years, three over three years, five over four years, and two over eight years, the average being 1·63 years.

4. *Presence of ulceration.*—In a large proportion of the patients who present themselves for treatment ulceration of the growth is found. In 12 cases where any mention of the appearance of the breast is made seven were in a state of ulceration, whilst two others presented a dusky red colour and were evidently on the point of breaking down. In one case the ulcer was five inches in diameter. Wagstaffe states that in more than half the number of cases ulceration is present when the patient is first seen. Schuchardt[12] found that in 61 out of 70 cases ulceration was present.

Although a history of previous injury to the breast can often be obtained in women as well as in men, yet in the latter the history seems, as a rule, to be much more definite. Another point that I have observed is the frequency with which the growth starts in or around the nipple. In the 37 cases collected by Warfield the nipple was involved in 18. This site for a tumour of the breast is also seen in women, but in the latter the neoplasm is usually a duct carcinoma, whereas this form of growth is exceedingly rare in men.

The treatment which should be adopted is, as in women, removal of the whole breast, the skin over the breast, the fascia covering the pectoralis major (and the muscle itself if involved), and all the fat and cellular tissue in the axilla. As in the female, if the growth only is excised recurrence quickly follows. Provided that the growth is not too extensive for removal the prognosis after operation is good.

In conclusion I am much indebted to Dr. Purcell, Mr. Jessett, and Mr. Waterhouse for permission to publish their cases; also to Dr. T. J. English for the excellent photographs which he was kind enough to take for me.

Wimpole street, W.

A CASE OF CONGENITAL DEFICIENCY OF BOTH UPPER LIMBS.

BY H. ASHLEY GAITSKELL, M.D. CANTAB.,

LATE HOUSE SURGEON TO GUY'S HOSPITAL.

THE following is an account of a case of congenital deficiency of the upper limbs and as this is a condition of rare occurrence I consider it worth recording.

On March 2nd, 1902, I was called to a woman four miles away in a country village in Northamptonshire who was stated to be in labour. When I arrived I found her up and walking about. On inquiry the pain did not seem to be severe enough for labour pains. I asked her when she expected to be confined and was told that it was not due for another month. I thought that it was advisable, however, to make an examination as there had been a considerable amount of "flooding." The abdomen was distended and the uterus was evidently enlarged, the enlargement corresponding to about the eighth month of pregnancy. The os was only slightly dilated and a soft mass projected from it which proved to be a small clot of blood. Beyond this I could with difficulty feel the head. Thinking it possible to stave off labour I prescribed opium and rest. I saw the patient on the next day and hæmorrhage had ceased. Two days later, however, I received an urgent message stating that the "waters had burst," and asking me to come at once. On arrival at the patient's house I was told that the child was already born but that he possessed no arms. I examined the child and found that he was alive but was evidently premature, about eight months as I expected. There was total absence of any signs of arms but otherwise the child was complete in every respect. I did not think he would live but requested the mother to allow me to have him photographed. The child, however, died in two days but I managed to secure a photograph of his body (Fig. 1). I also obtained permission to make a post-mortem examination, explaining that it was a case of considerable rarity and the opportunity ought not to be missed.

It was difficult to make out on feeling through the skin the existence of any clavicles or scapulæ, so I made an incision through the skin on the left side and a careful dissection revealed their presence; these were preserved in formalin and put aside till the opportunity arose for an accurate dissection of the parts, as I wished to know what had become of the glenoid cavity of the scapula and the muscles which normally arise from the clavicle or scapula and are inserted into the humerus. The arrangement I did find was as follows and is not without interest. Over the acromio clavicular joint and arising from its ligaments was a dense aponeurosis (Fig. 2) and into this most of the muscles were inserted (as far as I could make out from the smallness of the muscles I had to deal with). In the posterior region the supraspinatus, infraspinatus, and teres minor all arose from their normal places on scapula and were inserted into this same aponeurosis over the acromio-clavicular joint. There were no signs of the teres major, deltoid, or of the triceps. The aponeurosis arose from all those parts where the deltoid normally arises—namely, the spine of the scapula and the clavicle. Of the pectoral muscles I could only find one and this also was inserted into the aponeurosis. I did not attempt to dissect out the vessels and nerves, for these were of such small size that the time occupied would have been more than I had at my disposal. I next proceeded to clear the bones of all muscles, &c., and to investigate the condition of the various articular surfaces. The clavicle appeared to be quite normal, there being free movement at both the sterno-clavicular and acromio-clavicular joints; but it was otherwise with

the scapula, its axillary edge differing considerably from the normal anatomy of that part. The most prominent feature of the scapula is the condition of the coracoid process. Instead of being the normal small process, curved forward beneath and in front of the clavicle, it consists of one big process, being the continuation upwards of the body of the scapula. This extended behind, beneath, and above the clavicle, and there was a small articular surface between it and the clavicle. The tip of the process was capped with a large piece of articular cartilage. The size of this process, I presume, might be accounted for by the fact that owing to some error in development the cartilages of the glenoid cavity and the tip of the coracoid process had become fused into one common cartilage, possibly owing to some accidental jarring of the fœtus in utero, but this could scarcely cause a symmetrical deformity. There is an attempt at a glenoid cavity at the axillary end of the base of the spine of the scapula in the shape of a small boss of bone with small articular surface placed inferiorly to the spine of the scapula. Its position can just be seen underneath the aponeurosis (A) in Fig. 2. The acromio-clavicular joint was quite normal but for a large amount of fibrous tissue forming the aponeurosis arising from it. There were no signs of a coraco-acromial ligament. The biceps and all muscles which usually connect the two bones with the humerus appeared to be entirely absent.

I am greatly indebted to Mr. Thomas C. Pinny of Harlestone, Northampton, for the photograph illustrating the case.

Burgess Hill.

ON THREE CASES OF SUPRARENAL APOPLEXY IN CHILDREN.

BY FREDERICK LANGMEAD, M.B. LOND., M.R.C.S. ENG.,

MEDICAL REGISTRAR TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND STREET, LATE RESIDENT OBSTETRIC OFFICER, ST. MARY'S HOSPITAL.

THE possibility of almost sudden death in infants being due to hæmorrhage into the suprarenal capsules is so little recognised and so little is known about this disease that it seems worth while to record the following three cases with which I have come in contact.

CASE 1.—The patient was a baby, aged three days. The confinement was attended by St. Mary's Hospital Maternity Charity. He was a full term child and labour was easy. He never breathed freely; he cried but not vigorously; however, he got a fairly good colour and death was not anticipated. On the morning of the third day the breathing became grunting in character and the child moaned and refused to take the breast. On the same evening he had a general convulsion, with loss of consciousness, became black in the face, blood ran from the nose and mouth, and he died in half an hour.

Post-mortem examination showed the child to be fairly well nourished. The neck, the head, and the face were covered with a purpuric eruption. The navel was quite sweet. There were no marks of violence. The internal organs were all normal with the exception of the lung and the suprarenal bodies. The right heart was distended. The lower lobe of the right lung contained a large hæmorrhage which had burst through the bronchioles and could be traced up into the trachea and larynx and was evidently the source of the blood seen externally. The suprarenal bodies were reddish-purple in colour and stood out against the posterior abdominal wall. They were equally implicated and were moderately distended with what proved to be on section recent blood extravasation. Hæmorrhage was confined to the suprarenals, the surrounding structures being unaffected. The family history was not relevant. The mother had had three other children; there had been no miscarriages and there was no family disease.

CASE 2.—The patient was a boy, an only child, two months old. He had been entirely breast fed and had been perfectly healthy. He took the breast well and there had been no gastro-intestinal disturbance. On Feb. 29th, 1904, the mother fed him at 11 P.M.; he took the breast and she noticed nothing wrong and afterwards he went to sleep. On the next morning at 5 A.M. the mother noticed a change; the child was breathing heavily. She said, however, that the colour was good, that there was no loss of consciousness, that the fists were not clenched, and that there were no squint, no sort of fit, and no screaming or apparent pain. The natural functions were performed normally. The mother could not get the child to suck. However, he went to sleep for about ten minutes and then woke again and again refused the breast. He was then redressed and two little reddish-purple spots were noticed over the buttocks and one on the neck. Others were looked for but none were seen. He was brought up hurriedly to St. Mary's Hospital but died on the way. I saw the child at 7 A.M., just after death. There was a purpuric eruption over the face, the chest, and the abdomen, and there were a few spots elsewhere. He was a plump baby and there was nothing in the throat to indicate the cause of death, nor were there any external marks of violence. No history of tubercle, syphilis, rheumatism, or hæmophilia in the family could be obtained. There was no infectious fever in the neighbourhood. The child had not been vaccinated.

Post mortem nothing abnormal was found except suprarenal hæmorrhage and purpura. The heart, the lungs, the brain, the kidneys, and the spleen were all healthy. The suprarenals were equally affected, were dark purple in colour, and appeared to be distended with blood though only slightly increased in bulk. The hæmorrhage had not encroached beyond the organs themselves. There was no thrombosis of the renal or inferior cava veins. On section the medulla was seen to be more deeply tinted than the cortex which was reddish in colour. Microscopically the capsule was stretched, with effusion of blood beneath it in places. The cortex was distinctly recognisable but contained a considerable number of red blood cells. In some places in the cortex the parenchymatous cells were entirely replaced by blood, in others there were just a few gland cells left, while in a very few spots the parenchyma was little changed. The cortical cells which remained seemed normal and took the stain well. The medulla was greatly disorganised and showed marked necrotic change. The gland cells were indefinite in outline, swollen, and homogeneous, and took the stain badly; intermixing with them were many blood cells, greatly in the majority. The hæmorrhage into the medulla seemed to precede that of the cortex and here and there were clumps of brownish granules due to the breaking-down of hæmoglobin. There was no fatty change discernible and the blood-vessels were quite normal.

For the notes of the third case I am indebted to Mr. A. F. Cole, late resident medical officer of the Mildmay Mission Hospital, Bethnal Green, and to Dr. W. Gauld, medical superintendent of the same institution, for permission to publish them.

CASE 3.—The patient was a girl, aged seven months, who previously had been quite healthy and who was taken to the Mildmay Mission Hospital on Feb. 14th, 1904, because she had awakened screaming at 3.30 that morning. The onset of an exanthem was suspected and the mother was told to take the child again if the rash appeared. The temperature was 99·2° F. At 6 P.M. she was taken back again. The temperature was 104° and she was covered with an intense purpuric eruption far thicker on the extremities than on the abdomen where the patches were further apart. The child was now distinctly ill, warranting the giving of a bad prognosis. She died on the next morning in a convulsion just 22½ hours after the initial screaming fit and 12 hours after the purpura had appeared. No history of small-pox, scarlet fever, measles, &c., occurring in the neighbourhood could be obtained. She had been breastfed from birth and had had no drugging or patent food.

Post mortem the child was found to be an ordinary specimen, such as the neighbourhood produces, with no excess of fat on the body. Nothing abnormal anywhere was found except in the suprarenals. There was no hæmorrhage from the mucous or serous membranes. The suprarenals appeared as two masses of black blood clot, nearly half the size of the kidneys themselves, giving a remarkably vivid appearance on disturbing the intestines. Hæmorrhage was equally marked on both sides and was confined to the suprarenals.

The state of our ignorance of the etiology of suprarenal hæmorrhage is sufficiently exemplified by the number of theories which have been put forward. Spencer,[1] from examination of stillborn children, 20 per cent. of whom he found had suprarenal hæmorrhage, believed the prime factor to lie in the delicacy of the fœtal blood-vessels in this organ either normally or as the result of syphilis. The additional strain necessary to cause rupture of the delicate blood-vessels he ascribed chiefly to mechanical squeezing by the uterus during labour and to external violence, while he considered that asphyxia held a place of quite secondary importance. In support of this view he instanced his own cases, most of which succeeded difficult labour and especially breech births where manual interference is so often needed. Mattei[2] considered that the large, heavy infantile liver was pressed back against the posterior abdominal wall during labour, squeezing the inferior vena cava against the vertebral column, and so damming back the blood into the suprarenals and causing it to burst its bounds. Against these theories is the fact that in many cases a note has been made that labour was easy. Still,[3] in 1898, from an analysis of 18 cases of hæmorrhage and congestion (the only ones he was able to collect), believed that while trauma and asphyxia would account for many of the cases in stillborn children and children dying within the first few days of birth, it was insufficient to explain those occurring later. After the fifth day he suggested that the cause might be found in fatty degeneration of the arterial walls. Others he believed to be due to a toxin. Hutinel[4] advanced the theory that suprarenal hæmorrhages were preceded by thrombosis of the renal and inferior caval veins, into which the plexuses of the organ empty, resulting in consequent engorgement of these plexuses and subsequent rupture. Many authorities believe this condition to be symptomatic of an acute specific fever, at any rate in the older infants. Hamill[5] was able to collect from various sources 90 cases of children in whom suprarenal hæmorrhage or congestion occurred. These include 28 stillborn children, while some are merely pathological reports. From an exhaustive study of the literature of these cases and from careful analysis he apportioned them into three groups: (1) those in which death occurs during or before labour, due to manipulation and trauma; (2) those in which it occurs between birth and detachment of the cord, due chiefly to infection of the cord; and (3) those dying afterwards in which the cause is of an infectious or toxic nature. Of the 90 cases by far the greatest number belonged to the first group while only 11 came under the last heading.

There can be no doubt that while asphyxia and trauma can account for the great bulk of cases yet there is separable a small class, as pointed out by Eustace Talbot,[6] for the explanation of which we must look farther afield. This group consists of cases of death occurring in older infants and is a very limited one. Talbot only reports four, to which he added two which came in his own experience. Into this group my last two cases fall. Those which come under this head are characterised by a very definite train of symptoms. A child previously well is suddenly seized with acute abdominal pain and vomiting and rapidly becomes seriously ill. The temperature rises and an exanthem is often suspected. No characteristic rash, however, appears although sometimes there is purpura. In a few cases there are other hæmorrhages resembling the "purpura fulminans" of Henoch, convulsions generally supervene, the patient becomes moribund, and death occurs in a period which may be counted by hours. It is to explain these cases that the toxæmic theory is called to our aid and seems most nearly to answer the question.

Firstly, there is a close resemblance between the clinical records of these cases and of those of acute specific diseases of a malignant type. Secondly, there is no lack of experimental evidence suggestive of a toxic origin. Gärtner[7] isolated a bacillus like the colon bacillus, but not identical, which caused visceral hæmorrhage in dogs by intraperitoneal injection and recovered it from the animal's blood. Klebs and Eppinger[8] isolated a micrococcus in cases of hæmorrhage into the viscera of children. Roux and Yersin[9] caused congestion of the suprarenals by injection hypodermically of diphtheria bacilli into rabbits, guinea pigs, and pigeons. Langlois and Charrin[10] produced engorgement of the suprarenals by injection of bacillus pyocyaneus. Pelliet[11] obtained a like result by subcutaneous injection of essence of cloves into rabbits and guinea-pigs. Roger[12] used a virulent culture of Friedländer's bacillus and produced in guinea-pigs engorgement and effusion into those glands. Talbot[13] isolated from one case a streptococcus like pyogenes aureus but which differed from it in that it coagulated milk. Riesman[11] found staphylococcus aureus and albus in pure culture from the blood and tissues of four cases.

, p. 537.

Taking these data into consideration the possibility of a toxæmic origin becomes a probability but there are many difficulties. In the first place, it is surprising that in nearly every case in which bacteriological examination has been made the result proved negative. Then, again, in no case is there evidence of exposure to any source of infection, and furthermore, while profound toxæmia, the result of specific infection as in diphtheria and summer diarrhœa, is a common cause of death in children, cases of hæmorrhage into the suprarenals are very rare. If it be an infection presumably it is a special infection of unknown origin. I advance the crude state of our knowledge of this not unimportant condition as sufficient excuse for the publication of these additional cases.

London.

FURTHER NOTE ON SOME ADDITIONAL POINTS IN CONNEXION WITH CHLOROFORMED CALF VACCINE.[1]

By ALAN B. GREEN, M.A., M.D. CANTAB.

(From the Government Lymph Laboratories.)

SINCE April, 1903, the date of my preliminary note[2] on this subject, the preparation of calf vaccine by the chloroform process has been carried on at these laboratories and a large number of vaccines have now been treated by this method. These lymphs have been freed from their non-spore-bearing extraneous bacteria within a period ranging between one and eight hours after their collection from the calf and have, subject to the usual tests, been issued for general vaccination purposes about two weeks after collection. Their use has resulted in high "case" and "insertion" success. The following points in connexion with these vaccines have been investigated.

The effect of temperature in the elimination of extraneous micro-organisms from crude calf vaccine by the chloroform process.—It has been ascertained that the temperature at which vaccine emulsion is subjected to the chloroform process determines largely the rate at which the extraneous bacteria of that emulsion are eliminated. This has been shown in two ways. In the first set of experiments vaccine emulsion consisting of one part by weight of pulp and two parts by weight of water was divided into several equal portions. Each portion was then submitted to a pre-determined and separate temperature along with the set of apparatus to be used for its treatment with chloroform. These temperatures ranged from 10° to 37° C. In each case after both emulsion and apparatus had reached the requisite temperature of the experiment passage of chloroform vapour and air through the emulsion was effected. It was found by means of plate cultivations that elimination of extraneous micro-organisms was most rapidly effected in the case of the emulsions chloroformed at 37° C. and that elimination was most slowly effected in the case of the emulsions chloroformed at 10° C. Between these temperatures the gradation of germicidal action was very constant. The potency of these vaccines was subsequently tested by inoculations on calves, with the result that vaccines which had been subjected to the chloroform process at temperatures below 30° C. caused rather better vesiculation than the vaccines treated at temperatures above 30° C. In the second set of experiments vaccine emulsion, prepared as before, was divided into a number of equal portions, each of which was placed in a separate test-tube. In this case, the emulsions were all subjected to the chloroform process at 15° C. After the passage of chloroform vapour and air through the emulsions for half an hour, the entrance and exit of each vaccine tube were clamped in order that none of the contained chloroform might escape and the tubes were placed in temperatures ranging from 10° to 37° C. for 24 hours. In the case of these emulsions, where the amount of chloroform present in each must have been approximately the same, a similar gradation of germicidal action was evidenced as in the former set of experiments, elimination occurring most rapidly in the case of emulsions submitted to a temperature of 37° C. and most slowly in the case of emulsions submitted to a temperature of 10° C. The potency of each of these vaccine emulsions was tested as before by inoculations on calves, with the result that vaccines which had been submitted to temperatures below 30° C. gave slightly better vesicles than vaccines which had been submitted to temperatures above 30° C. Both series of experiments indicate that the temperatures at which extraneous bacteria are killed most quickly in vaccine emulsion by the chloroform process, the specific germ being left meanwhile in state of full activity, lie probably between 18° and 23° C

The species of micro-organisms killed by the chloroform process.—In addition to the extraneous micro-organisms mentioned in the preliminary note as commonly occurring in crude calf vaccine and as being eliminated therefrom by means of chloroform experiments have been made with further species of bacteria. These, with the exception of the bacillus proteus vulgaris and the bacillus coli communis, have never been found in vaccine lymph at these laboratories, but they have been subjected to the action of chloroform in order that knowledge of the germicidal value of that process might be extended. The bacteria thus experimented with are the bacillus proteus vulgaris, bacillus prodigiosus, bacillus pyocyaneus, bacillus fluorescens liquefaciens, bacillus coli communis, bacillus typhosus, bacillus diphtheriæ, bacillus mallei, bacillus pestis, bacillus tuberculosis, and spirillum choleræ Asiaticæ. Broth emulsions of these bacteria were first experimented with. As soon as an emulsion was established a suitable culture medium was inoculated with a small portion of it and duly incubated in order to ascertain whether the species of micro-organism in question could be easily recovered from the emulsion. The passage of chloroform vapour and air through the emulsion was then begun and during the process at regular intervals further cultivations were made from it. In every instance the bacteria of experiment were found to have been killed at intervals ranging from one to eight hours from the commencement of the process. In a second set of experiments vaccine emulsions were prepared by mixing one part by weight of pulp with two parts by weight of water. To these emulsions the bacteria to be experimented with were added and cultivations were at once made therefrom in each instance to ascertain whether recovery of the bacteria was possible. Passage of chloroform vapour and air through the emulsions was then carried out and further cultivations were made from them from time to time. As in the case of the broth emulsions, after the passage of the chloroform vapour and air for a few hours the bacteria in the vaccine emulsions were killed. In the case of each experiment of the two foregoing series a "control" preparation was established in which the bacteria were found to be still alive after the bacteria of the corresponding experimental preparation had been killed. The vaccine used in these experiments was collected for experimental purposes only.

The keeping properties of chloroformed vaccines.—The keeping properties of chloroformed vaccines have been tested in the following ways. First, vaccine lymph freshly collected from the calf was divided into two portions. One portion after emulsification with water was subjected to the chloroform process and after elimination of its extraneous micro-organisms the chloroform was partly removed by the passage through the emulsion of a stream of sterile air. The other portion was emulsified with 50 per cent. of glycerine and water solution. These chloroformed and glycerinated emulsions were, within 24 hours of their collection from the calf, each subdivided into five parts, one part of each being stored at 10°, 20°, 25°, 30°, and 37° C. The potency of these several parts was subsequently tested on calves at regular intervals of time. The result showed (*a*) that the highest potency was retained for the longest time, alike for the chloroformed and glycerinated portions, by the emulsions stored at 10° C., for the shortest time, alike again by both portions, by emulsions stored at 37° C.; and (*b*) that the potency as between the chloroformed and glycerinated vaccine kept at any one of the foregoing temperatures was practically the same, the only marked difference occurring in case of the vaccines kept at 37° C., a temperature at which the chloroformed emulsions retained potency for a longer period than did the glycerinated emulsions.

[13] St. Bartholomew's Hospital Reports, 1900.

[14] Post-Mortem Reports, University Hospital, Philadelphia.

[1] A paper read before the Royal Society on May 5th, 1904.

Proceedings of the Royal Society, 1903, and THE LANCET, June 20th, 1903, p. 1738.

Upon the completion of the foregoing experiments, a further number of vaccines collected from vesicles of good average quality were emulsified with water in the proportion of one part by weight of pulp to two parts by weight of water, and subjected as before to the chloroform process. When elimination of their extraneous bacteria had been effected part of the chloroform was removed from the emulsions and these were placed in the ice-chest at 10° C. Immediately prior to the issue of these vaccines the remainder of the chloroform was removed and glycerine was added in the proportion of two parts by weight of glycerine to the original weight of vaccine pulp. These vaccines were later, after passing the requisite tests, issued for general vaccinating purposes, a similar interval being allowed to elapse between their collection from the calf and subsequent issue as is usual at these laboratories in the case of glycerinated vaccine—namely, about six weeks. In the case of two of these chloroformed vaccines an interval of two months elapsed between collection and issue. The use of these chloroformed vaccines has been attended with results showing high "case" and "insertion" success.

Summary.—Experience of the further use of the chloroform process in the preparation of a large number of vaccines during the past year confirms the conclusions arrived at in the preliminary note. And meanwhile important additional knowledge has been gained—namely, that chloroformed calf vaccine, if originally of sufficiently high potency, will, when prepared and stored under suitable conditions, retain for a considerable time a high degree of potency and this notwithstanding that the extraneous organisms had been rapidly eliminated from it in an early stage of its preparation.

WOUND OF THE LEFT THORAX, WITH EXTENSIVE LACERATION OF THE PLEURA, ETC.

BY E. WYNSTONE-WATERS.

ON March 20th, at about 2.30 A.M., I was awakened by the arrival of a number of natives at my house and I soon discovered that one of them, a man of about 25 years of age, had received a severe wound with a native knife. The wound occupied the left ninth intercostal space, its direction being oblique and parallel to the ninth rib, and extended posteriorly somewhat beyond the posterior axillary line, while in front it reached the anterior axillary line. The wound implicated the parietal pleura in nearly its whole length, except posteriorly where the incision became more superficial. The visceral pleura was also implicated, but to a less extent, and the lung tissue was lacerated. At the time I made the examination there were very considerable hæmorrhage and at first a marked whistling sound which, however, soon became indistinct. Pneumothorax was established, air having rushed in and separated the parietal and visceral pleura, and the lung was somewhat collapsed in virtue of its elasticity.

The wound having been thoroughly cleansed I did not attempt to reduce its size, thus being certain of a more efficient drainage and at the same time obtaining a larger field for observation. On the next day on removing the dressings I found that a considerable amount of hæmorrhage had occurred, while the external aperture was filled by a closely fitting plug of lung tissue which protruded somewhat beyond the external surface. No attempt was made to reduce this protrusion but it was kept thoroughly aseptic. The protruded lung was quite healthy and showed considerable crepitation due to the residual air. On the fourth day slight but steady pressure was applied to the protruded lung tissue and a firm compress of carbolic tow was strapped over the part. On the fifth day on removing the dressings I found that the lung tissue had yielded to the continued pressure of the compress and was inside the thoracic cavity. Shortly after this granulations were seen to be rapidly springing up all round. The area at first occupied by the plug of lung now presented a pink field of healthy newly formed tissue, only a very slight amount of pus being present on the dressings. The wound was kept plugged with cyanide gauze, so that the cavity was filled with healthy tissue from the very bottom, there being no opportunity for the development of any sinuses or other false cavities. Skin gradually spread from the edges of the wound and was soon seen to cover up the whole site of the lesion, except where a few exuberant granulations prevented its further encroachment. These islands of new tissue, however, soon yielded to a few touches from a crystal of blue stone and the skin rapidly covered up their original site.

This case is one of exceeding interest to the physiologist as well as to the pathologist and surgeon, showing nature in one of her happiest moods. The patient belongs to the Waswahili, a subdivision of the Bantu section of the African negro, a race occupying a "thin line along a thousand miles of creeks and islands" on the East coast of Africa. The protruding portion of lung by its constant pressure caused inflammatory adhesion to take place between the visceral and parietal pleura along the line of pressure, thus completely sealing up the rent into the pleural cavity and establishing a continuity of parietal and visceral pleura—in fact, producing a condition resembling the normal pleura—viz., a closed sac. The air in this now closed sac becoming rapidly absorbed, the lung expanded and the parietal and visceral layers of the pleura coming into apposition the normal process of respiration was again established. Doubtless in time the inflammatory adhesion of the pleura at the peripheral margin will become fibrous and the exposed surface of lung, which has been forced to retire within its own cavity, will adhere and become united by fibrous tissue to the scar tissue filling the original wound. Thus, by a perfectly natural process, aided by strictly antiseptic precautions, an exceedingly severe and dangerous wound was closed, the only drawback or compensation nature will impose being a somewhat diminished "vital capacity" on the affected side.

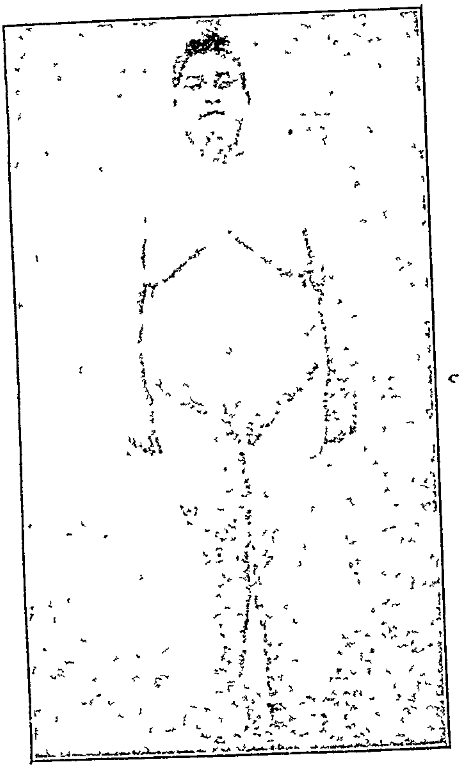
GYNÆCOMASTIA.

BY EDWIN S. CRISPIN, M.R.C.S. ENG., L.R.C.P. LOND.,
CIVIL SURGEON AND HON. BIMBASHI, EGYPTIAN ARMY.

I READ with interest the article on Gynæcomastia in THE LANCET of March 26th, p. 865, by my colleagues, Mr. A. Webb Jones and Dr. J. B. Christopherson as I happened to be at Merowi when I received that number of THE LANCET where Case 1 is still at work and where also I found a third case. I regret that I was unable to get a photograph of the latter as I had not my camera with me; he has a distinct gland in each breast of the size of a small Tangerine orange which can be easily moved over the muscles of the chest; the nipples are also well developed. He also is a Sudanese, a Nubawi, Case 1 being a Furawi, not a Firtitawi, as mentioned in that article, but, however, they all come from the neighbourhood of Darfur.

I believe that gynæcomastia is not at all an uncommon condition amongst the Sudanese of Central Africa. I saw two or three more cases amongst the Dinkas and Baris while I was travelling on the Bahr-el-Ghebel between Lake No and Gondokoro. Sir Harry Johnston in his book, "British Central Africa," gives a very good reproduction of a photograph of a similar case on p. 399 and says it is very common amongst Sudanese. I do not think that he can have confused these cases with those of prominent pectoral development of fat and muscle, as a digital examination would at once settle the [illegible] but in a photograph these cases are very similar. [illegible] photograph taken by Dr. J. Warnock the F[illegible]m, of a case of this latter sort.

apparent female breasts being chiefly due to excessive fat. I believe the condition of gynæcomastia is extremely rare amongst Egyptians, as during several months spent all over



Egypt examining conscripts for the Egyptian Army at the rate of about 300 a day I only remember seeing one case.

ROYAL FREE HOSPITAL.

A CASE OF REPEATED INTESTINAL OBSTRUCTION FOLLOWING AN OPERATION FOR REMOVAL OF A CYST OF THE PELVIS; RECOVERY.

(Under the care of Dr. T. O. HAYES and Mr. T. P. LEGG.)

FOR the notes of the case we are indebted to Mrs. F. E. Willey, M.B., surgical registrar to the hospital.

The patient, a young unmarried woman, aged 20 years, was admitted to the Royal Free Hospital on March 4th, 1902, under the care of Dr. Hayes, suffering from prolapse of the uterus. She stated that 12 months previously a "lump" had appeared at the vulval orifice but it had caused her no inconvenience. Six months afterwards the lump became much larger and appeared directly she got out of bed in the morning and remained at the vulval orifice till she pushed it up again, which she did every night on going to bed. A month before admission she had had some trouble with micturition, which, however, only seems to have been very slight. She had always suffered from constipation and a year ago she had an acute illness, characterised by severe abdominal pain, complete constipation, and vomiting which was described as fæcal. At this time she was in bed for three weeks. The menstrual periods had always been regular but scanty.

On examining the abdomen a smooth, rounded, elastic swelling was found arising out of the pelvis rather more on the right than on the left side and reaching as high as the umbilicus; it crossed the mid-line and on the right side extended outwards into the iliac region as far as the anterior superior iliac spine. On percussion a dull note was obtained over the swelling, in which a fluid thrill was obtainable. The rest of the abdomen presented nothing abnormal and it was quite soft. Per vaginam the uterus was found to be prolapsed completely. It could be replaced in the vagina, but the abdominal swelling, which bulged into the posterior cul-de-sac, prevented complete reposition. Bimanually the swelling in the abdomen was found to be continuous with that in the posterior cul-de sac of the vagina. The cervix uteri was greatly hypertrophied and softened. The external os was small. A sound passed one inch beyond the normal length.

On March 15th Dr. Hayes opened the abdomen in the mid-line above the pubes. Much difficulty was experienced in defining the tumour owing to the presence of numerous old adhesions which matted the tumour and intestines to one another and to the parietes. During the separation of the adhesions the tumour was ruptured and a thin, yellow, cloudy fluid escaped. The ovary was found to be considerably enlarged. The tumour, ovary, and tube having been isolated were brought up to the surface of the abdomen and the pedicle was ligated by interlocking sutures of thick silk which were buried in the stump of the broad ligament and tube by suturing the peritoneum over the raw surface. The wound was closed by three layers of sutures, no drainage being employed as there was no oozing after the parts had been wiped thoroughly. On examining the specimen it was found to consist of (1) a smooth-walled cavity containing six ounces of yellowish fluid, apparently a cyst of the broad ligament; (2) the Fallopian tube, which was one and three quarter inches long, closely connected with the wall of the cyst, but not opening into it; and (3) an enlarged cystic ovary which also did not appear to be connected with the cyst. The fluid in the cyst was alkaline and had a specific gravity of 1013. Microscopically blood cells only were found. The left ovary was considerably enlarged and bound down by adhesions. On account of the patient's age and the absence of any other evidence of disease it was not removed. During the first 24 hours after the operation the patient vomited frequently, the pulse was under 100 per minute, and she made good progress till the 19th, on which day vomiting recurred and she had a good deal of pain in the lower part of the abdomen. An enema and an aperient did not open the bowels, but the vomiting was checked by refraining from giving her anything by the mouth. On the 22nd the bowels were opened, the pain in the abdomen was less, and the pulse rate was 96. On the 24th vomiting recommenced and became more and more frequent until in the evening it was distinctly feculent. She was obviously very ill. The pulse-rate rapidly increased to 120 per minute and the abdomen became distended. Peristalsis of the intestine was quite easily visible. Mr. Legg decided to open the abdomen, which was done through the former operation wound. A broad adhesion was found binding the subjacent coil of the intestine to the line of the scar and kinking it, the intestine above being much distended. In separating this coil the wall of the bowel was denuded of its peritoneal coat for about two inches of its length. Many other adhesions, some recent and others of older formation, were separated and the bowels were freed as much as possible. In this proceeding a small cavity containing recent blood clot was found in the right side of the pelvis. A drainage-tube was placed in this cavity and brought out through the lower part of the incision, the rest of the wound being entirely closed. Both before and after the operation, whilst the patient was under the anæsthetic, the stomach was washed out with hot water and a couple of ounces of haustus sennæ were put into the stomach before the tube was removed. She vomited at once on coming round from the anæsthetic. Five minims of liquor strychninæ were given hypodermically every four hours and a drachm of sodium sulphate every two hours. At the end of 24 hours she was able to take fluid nourishment without being sick and her general condition was greatly improved in every respect. This continued till the early morning of the 28th, when the vomiting and pain returned with increased severity, the abdomen became distended, and peristaltic movements of the bowel were easily seen. Her bowels had not been opened since the operation in spite of turpentine enemata, castor oil, &c. The wound was again opened; the adhesions were very numerous and many fresh ones seemed to have formed, binding down the intestines, the most adherent coil of which was freed and fixed to the upper angle of the wound without opening it. As before the patient was much relieved by the operation and she rapidly improved, the pulse coming down to nearly its normal rate and the bowels being opened twice on April 2nd. This state was maintained till April 6th when the previous symptoms again recurred, the pulse rapidly rising to 116. The wound was reopened; a coil of the small bowel was found considerably distended and fixed by adhesions in the neighbourhood of the scar and was severely kinked. On tracing this portion of bowel it was found to be continuous with that which had been fixed to the upper angle of the wound; below it was tightly bound down to the brim of the pelvis. This loop was brought out of the wound and isolated by packing off the rest of the abdominal cavity with gauze. It was covered with protective and ordinary dressings were applied. During the next two or three days the patient was very ill, the chief symptoms being vomiting and abdominal pain, but the pulse kept about 100 per minute. On the 12th the bowels were opened naturally and afterwards they acted regularly. On the 14th the gauze packing was removed, a smaller amount being lightly replaced on each side of the loop, which had become partly withdrawn into the abdominal cavity and was covered by granulations. Slowly the whole loop was withdrawn and as this took place the wound closed, so that on May 28th only a small granulating area was left and she was in excellent health. The bowels acted daily with the aid of a belladonna and aloes pill. On June 19th she left the hospital.

Remarks by MR. LEGG.—This case presents some features of interest. In the first place, the extent of the adhesions found at the operation for the removal of the cyst was somewhat unusual. These were, no doubt, the result of the acute abdominal attack (which seems to have been due to acute peritonitis) which she had suffered from a year before admission. The patient had not had any children or miscarriages and there was no history of a vaginal discharge. In the second place, the repeated attacks of intestinal obstruction coming on at short intervals and developing acutely when the patient appeared to be progressing favourably. This patient had three attacks in less than a fortnight—viz., on March 24th and 28th and on April 5th. The patient's condition after the operation for removal of the tumour was not very satisfactory. She had considerable abdominal pain, repeated attacks of vomiting, and there was a good deal of difficulty in getting an action of the bowels. On the ninth day the symptoms of intestinal obstruction became unmistakeable and developed acutely. The relief obtained by opening the abdomen and separating the adhesions was immediate but it only lasted a few days, for on March 28th all the symptoms recurred. At this operation, which was done by my colleague Mr. E. W. Roughton, the loop of intestine which was fixed to the wound was not opened because it was impossible to tell which part of the small bowel it belonged to and if it had been high up in the jejunum a fistulous opening in the worst position would have resulted. Further, it was hoped that by freeing the adhesions the obstruction would be relieved and if not the loop fixed to the abdominal parietes could be opened at once. These hopes were fulfilled and on April 2nd the bowels were opened but on the 5th all the signs of intestinal obstruction were again present and the abdomen was reopened. It appeared to be always the same loop of intestine which was giving rise to the symptoms—viz., that piece which had been stripped of its peritoneum at the first operation for the relief of the obstruction. Resection did not appear to be possible as the loop was firmly bound down to the posterior part of the brim of the pelvis. The only method feasible was to isolate this loop by bringing it out of the wound and so shutting it off from the rest of the abdominal cavity. If the patient recovered further operative treatment could then be undertaken. The bowel above the loop attached to the skin was not greatly distended, therefore it was not opened. For some days there was a good deal of abdominal distension but the vomiting soon ceased and the pulse remained slow. The loop was slowly withdrawn into the abdominal cavity; it was covered with granulations and there must have been many adhesions around it, yet no signs or symptoms of intestinal obstruction again arose. At the present time the patient is in perfect health. Her bowels act regularly with the aid of an aperient pill. For some time after the operation she wore an abdominal belt but she has long since discarded it and there is very little bulging of the scar.

LIVERPOOL INFIRMARY FOR CHILDREN.

FOUR CASES OF STRANGULATED INGUINAL HERNIA IN INFANTS AGED 17 DAYS, FIVE WEEKS, FOUR MONTHS, AND 12 MONTHS.

(Under the care of Mr. R. C. DUN.)

CASE 1.—The patient was a male, 17 days old. This infant was breast-fed. There had been vomiting several times daily since birth but the bowels had moved regularly. Three days before admission to the hospital he became restless, appeared to be in severe pain, and began to vomit frequently. A medical man was called in and strangulated left inguinal hernia was diagnosed. Attempts at reduction failed. The following day all the symptoms were aggravated. The vomited matter became green. A soap-and-water enema resulted in slight movement of the bowels. 72 hours were allowed to elapse after the hernia was first noticed before the infant was brought to the hospital. On admission he was in a collapsed state; an irreducible hernia occupied the left inguinal canal and scrotum. No phimosis was present. Operation was at once undertaken. The constriction was found at the internal abdominal ring and divided. On opening the sac, which was congenital in type, two or three drachms of blood-stained serum escaped. The contents were a coil of small intestine deep violet in colour but retaining its gloss. The seat of constriction was examined. A considerable degree of anæmia was present, particularly at the point of exit, but the surface was smooth and glistening and the appearances seemed to warrant a return of the intestine. This was carried out. The sac was ligatured at its neck, the distal portion was removed, and a radical cure was performed. The child's condition was grave for several hours after the operation but gradually improvement occurred. The bowels moved three times during the first 24 hours, there was no vomiting, and all appeared to be going well. 12 hours later a sudden change for the worse occurred, the pulse became feeble, the temperature, previously normal, rose to 101° F., vomiting occurred several times in rapid succession, and death followed 36 hours after the operation. No signs of inflammation were present about the incision.

Necropsy.—At the post-mortem examination no peritonitis was found. The strangulated loop of small intestine was recognised three feet six inches from the ileo-cæcal valve. It was deeply congested, smooth, and shining. The circulation had returned to the anæmic areas of constriction noted at the operation. On opening the bowel the mucous lining of the strangulated loop showed marked inflammatory infiltration. Corresponding to the seat of constriction at the point of exit there was present an almost complete ring of small, superficial, irregularly shaped ulcers. The mucous membrane of the intestines and stomach was otherwise normal in appearance. A Meckel's diverticulum was present two feet nine inches from the ileo-cæcal valve—i.e., nine inches below the strangulated loop of intestine. This process was just over one inch in length and communicated with the lumen of the bowel by an opening of the size of a threepenny-piece. From the apex of the diverticulum a thin fibrous band passed upwards and to the right, crossing anterior to the ileum five inches distal to the root of the diverticulum. This band was two inches long and gained attachment to the mesentery one and a half inches from its free border. The small intestine at the point of origin of the diverticulum was drawn towards the mesenteric attachment of the band. Thus a vertically placed loop of ileum was formed, the proximal end of which corresponded with the root of the diverticulum, while its distal extremity was the portion of small intestine lying behind the fibrous band. The band in question as it crossed the ileum lay in contact with its anterior surface. No adhesion existed between it and the underlying intestine. The small gut distal to the band was empty and collapsed, as also were the cæcum and large intestine. The bowel above the band was slightly distended. The tips of three fingers could be inserted under the band.

CASE 2.—The patient was a male, five weeks old. He was breast-fed and had had good health up to the present illness. Late one evening, after 18 hours' constipation, he was suddenly seized with severe pain, causing violent attacks of screaming, and vomiting occurred. The mother noticed that the right side of the scrotum was swollen and hard a few minutes after the onset of the symptoms. The family medical attendant was called in and gentle taxis failed to reduce the rupture. Cold compresses were applied throughout the night and the legs and pelvis were elevated. Vomiting and pain continued at intervals and the breast was refused. Mr. Dun saw the child 12 hours after the appearance of the symptoms; the bowels had not moved and no flatus had been passed during the night. A large irreducible right scrotal hernia was present; the testicle lay behind the lower part. There was no phimosis. Chloroform was administered. Gentle attempts at reduction failed to make any impression on the size of the hernia so operation was immediately undertaken. On exposing the sac the constriction was found to be caused by the narrowness of its neck. The sac was opened and its neck was divided; it was of the infantile variety, a complete tunica vaginalis testis being present. No fluid was present in the sac. It contained a loop of small intestine, bright red in colour. The seat of the constriction was examined, the bowel was returned to the abdominal cavity, and a radical cure was carried out. The subsequent progress was satisfactory. No vomiting occurred after the operation and the bowels moved freely in six hours. The stitches were removed on the sixth day and recovery was uninterrupted.

CASE 3.—The patient was a male, four months old. This infant had been weakly since birth; he was artificially fed but had suffered from no gastro-intestinal disturbance. There had been no cough. When three weeks old an inguinal hernia appeared on the right side and a truss was applied a week later. At the sixth week a left inguinal hernia made its appearance and a double truss was applied which had since been worn regularly. At the age of three and a half months the infant was taken to the Children's Infirmary on account of phimosis; this was well marked and circumcision was recommended. The truss worn was well fitting and controlled the hernia satisfactorily; during the 12 weeks it had been in use the hernia on the right side had not been down while the left hernia had appeared twice. The infant was circumcised and all went well until the fifteenth day after the operation when the child was suddenly seized with severe pain. The hernia on the right side was found to have come down under the truss. The truss was removed but the mother could not get the hernia back. 18 hours later the child was taken to the hospital. Vomiting had occurred frequently during the night; there had been little pain since the onset of symptoms but nothing had passed by the bowels. There was present a large scrotal inguinal hernia on the right side which was tense and irreducible. The child was collapsed. Operation was performed. The constriction was found at the internal abdominal ring. The sac, of infantile type, contained the cæcum, vermiform appendix, and about one inch of the ileum above the ileo-cæcal valve. The condition of the bowel was good; the appendix was ligatured and removed, the intestine was replaced in the abdomen, and a radical cure was performed. The bowels moved twice in the 12 hours following the operation and there was no vomiting. The healing of the wound ran an aseptic course. The stitches were removed on the seventh day. On the fourth day after the operation diarrhœa set in; from being slight at first this gradually increased in severity and, in spite of dietetic and therapeutic treatment, the child died exhausted 19 days after the operation.

Necropsy.—At the post-mortem examination no peritonitis was found. There was slight congestion of the cæcum externally. On opening this portion of the intestine numerous small ulcers of the mucous coat were seen; they were present at the ileo-cæcal valve but did not extend into the small intestine. The mucous lining of the colon was unaffected.

CASE 4.—The patient was a male, 12 months old, who was artificially fed. A left inguinal hernia had been present since the age of six weeks. A truss had been worn regularly but had not completely controlled the rupture. For a few weeks before the present illness the child had suffered from a bad cough and the hernia came down frequently under the truss and was more difficult to reduce than formerly. The bowels had been acting regularly. Ten hours before Mr. Dun saw the child the hernia was noticed to be down and could not be reduced. When seen vomiting was frequent and neither fæces nor flatus had been passed. The left scrotum was œdematous and red and contained an irreducible hernia. No phimosis was present. There was bronchitis in both lungs. Under chloroform the hernia was still irreducible. The operation showed a sac of infantile type, containing a portion of small intestine in good condition. The constriction was at the internal ring outside the sac. A radical cure was performed and recovery was uninterrupted.

Remarks by Mr. DUN.—Strangulated inguinal hernia is comparatively rare in childhood. The above four examples are of particular interest on account of their occurrence during the first years of life. The adhesion of a Meckel's diverticulum to a distal portion of the mesentery may, I think, be fairly considered as the causal factor in producing the hernia in Case 1. Although insufficient to cause obstruction, it undoubtedly led to a certain amount of abnormal fixation of the intestine in its neighbourhood. Thus some interference with peristalsis probably occurred leading to increased muscular contraction in the bowel. This additional peristaltic effort, put forth to overcome increased resistance, may have led to the forcing of the loop of ileum, only nine inches above the adhesion, into a patent funicular process. The occasional vomiting which was present from birth may have been due to the same cause.

As regards causation, in each of these cases the important predisposing factor, a patent funicular process, existed. As an exciting cause in Case 1 increased peristalsis the result of distal resistance by an adherent Meckel's diverticulum was the probable factor. In Case 2 constipation of short duration was the only apparent cause. In Case 3 marked phimosis was present. In Case 4 severe cough was the most obvious cause of strangulation in a previously existing hernia. Dealing with treatment the probable failure of taxis, even when immediately resorted to, is exemplified. The importance of early operation cannot be too strongly urged owing, firstly, to the rapidity with which collapse ensues and, secondly, on account of the constantly increasing danger of ulceration of mucous membrane subsequently occurring in intestine the external appearance of which would seem to warrant its return to the abdominal cavity at the time of operation. Collapse was present in Cases 1 and 3, in which strangulation had been present 72 and 18 hours respectively, while in Cases 2 and 4 of 12 and 10 hours' duration it was absent. Ulceration of the mucous membrane occurred in Cases 1 and 3 and was probably the cause of death in both. The fatal issue in Case 1 was rapid and apparently due to septic absorption from the ulcerated surface; in Case 3 it resulted from exhaustion following upon chronic diarrhœa.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

The Glomerular Lesions of Diffuse Nephritis.—Malignant Growths.—Primary Sarcoma of the Liver in an Infant.—Sarcoma of the Alimentary Canal.—Leukanæmia.

A MEETING of this society was held on May 17th, Dr. P. H. PYE-SMITH being in the chair.

Dr. W. P. HERRINGHAM and Dr. J. H. THURSFIELD communicated a paper on the Glomerular Lesions of Diffuse Parenchymatous Nephritis. They said that much difference of opinion existed as to the exact significance of the microscopic appearances found in the glomeruli in this disease. Hitherto the appearances had been supposed to represent fibrous tissue but the great difficulty in accepting this view lay in the fact that epithelial cells, the proliferation of which was the striking feature of the disease, did not elsewhere give rise to fibrous tissue. The microscopic appearances were described in detail and illustrated by a series of lantern slides, the contention being that a continuous and connected process could be traced from the first proliferation of the epithelial cells up to the production of the degenerate or functionless glomerulus. The causation of the degeneration was attributed to chemical or bacterial poisons rather than to any mechanical force.

Mr. C. E. WALKER read a paper on the Cytology of Malignant

Growths, dealing with the recent work done upon malignant growths by Professor J. B. Farmer, Mr. J. E. S. Moore, and himself. After a description of the somatic and heterotype mitoses and of the occurrence of the latter in malignant growths Mr. Walker went on to say that though the tissue forming malignant growths resembled normal reproductive tissue in many other respects than in the presence of the heterotype and homotype division figures, there were, particularly in the case of animals, some important points of difference. This resemblance and difference had been emphasised by the application of the term "gametoid" to the mature cancer cells to distinguish them from the gametic cells which arose from gametogenic tissue. Up to the present time the collaborators had seen nothing that could be seriously interpreted as evidence of fusion or fertilisation of the cells forming malignant growths. The occurrence of reduced cells naturally suggested the possibility, or perhaps probability, of fusion, and to them it did so particularly in view of what happened in the case of certain ferns observed by Professor Farmer, Mr. Moore, and Miss Digby more than a year ago. [illegible] e stimuli to prothallial tissue [illegible] ertilisation and the production [illegible] taking place in some cases [illegible] elements appearing. The [illegible] ged cases of nuclear fusion in [illegible] tful or at any rate too few to [illegible] generalisation. Mr. Walker said that his collaborators and he attached great importance to the occurrence of the heterotype mitosis and the consequent production of reduced tissue as being intimately connected with the malignant characters of the growths in which it was found. Since they, on Dec. 10th last, recorded its presence in malignant growths occurring in man Dr. E. F. Bashford and Dr. J. A. Murray had recorded its presence in malignant tumours in many other vertebrates as well as in man. The [illegible] and preparation were necessary if mitotic figures were to be observed this involved no loss of time. As a proof of this Mr. Walker referred to a slide of epithelioma which was among those under the microscopes. It was from a case operated upon that afternoon and had been fixed in acetic acid and alcohol, imbedded in paraffin, cut, stained to show nuclear divisions, and mounted in Canada balsam within four hours.

Dr. E. P. **BAUMANN** and Dr. J. G. **FORBES** described a case of Primary Sarcoma of the Liver in an Infant. The patient, a male infant, aged 11 months, was admitted to the Hospital for Sick Children, Great Ormond-street. He had suffered for some four weeks from vomiting, loss of flesh, and enlargement of the abdomen. On admission he was very pale but not jaundiced. The liver was enormously enlarged, forming an elastic, semi-fluctuating mass. Death occurred a week after admission. At the necropsy several massive deposits of friable new growth were found occupying practically the whole of the [illegible] had occurred into the deposits [illegible] found in any other tissues or [illegible] nation showed the growth to be of the nature of a round- and spindle-celled sarcoma. Some of the areas of hæmorrhage appeared as blood spaces lined by proliferating endothelial cells. Here the growth had the appearance rather of an angiosarcoma. Elsewhere in the middle of the growth proliferation of the endothelial cells of the capillaries was to be seen merging into the type of cell constituting the sarcoma and affording a possible clue to its origin.

Mr. E. M. **CORNER** *and Mr. H. A. T.* **FAIRBANK** *made* a communication on the Sarcomata of the Alimentary Canal. Mention was first made of a case of intussusception which complicated a sarcoma of the colon in a boy, nine years of age. This case was the eleventh recorded instance of sarcoma of the colon and the fifth in which a sarcoma had caused the formation of an intussusception. The tumour was a round celled sarcoma. The paper then dealt with sarcomata of the alimentary tract in general. 174 instances were collected. In these, males were affected twice as often as females. Those of the œsophagus and rectum seemed mainly to occur at the later periods of life; those of the ileo-cæcal region and the colon during the first decade. The œsophagus was affected 14 times, the stomach 58 times, the ileo cæcal region 65, the colon 11, and the rectum seven times. The round-celled variety was by far the most common. The prognosis of early operation seemed very good, six cases being free from recurrence from one to nine years afterwards.

Dr. F. **PARKES WEBER** read an account of a case of Leukanæmia with great Hyperplasia of the Spleen and Prevertebral Hæmolymph Glands and with Increase of Connective Tissue in the Bone Marrow. The patient, a man, aged 58 years, died after about a year's illness with progressive asthenia and symptoms somewhat resembling pernicious anæmia, though he had great enlargement of the spleen and the liver. The main features of the case could be summed up as follows: (1) progressive waxy pallor and asthenia with maintenance of subcutaneous fat; (2) changes in the red blood corpuscles rather similar to, but not so extreme as, those met with in true pernicious anæmia; (3) absence of true leukæmic changes in the blood but presence of slight myelocythæmia and of inverted proportion of lymphocytes to polymorphonuclears; (4) relative deficiency of pigment in the urine; (5) changes found after death in the hæmopoietic tissues similar to those of "mixed-cell" leukæmia or pseudo-leukæmia; (6) abnormally firm consistence and fibrous tissue increase in the bone marrow of the shaft of a long bone; (7) absence of enlargement of the ordinary lymph glands but hyperplasia of the spleen (hæmal gland) and hæmolymph glands; and (8) absence of any reaction for free iron in the spleen, the liver, or the kidneys such as occurred in pernicious anæmia. Similar cases had doubtless been described as pernicious anæmia merging or becoming transformed into leukæmia.

At the close of the ordinary meeting the annual general meeting for the election of officers and council was held. A vote of thanks was passed to Sir Samuel Wilks who retired from the office of trustee. The members nominated by the council to hold office during the ensuing year were duly elected.

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.

Quantitative and Qualitative Leucocyte Observations in Various Forms of Insanity.—Social Causes of Alcoholism.—Combined Spinal Degeneration with Unusual Mental Symptoms.

THE quarterly general meeting of this society was held on May 18th at the Langham Hotel, Portland Place, London, W., under the presidency of Dr. **ERNEST W. WHITE**.

The report of a committee of the association which was appointed to investigate further the remarkable case of multiple consciousness in a girl brought before the society by Dr. Albert Wilson last year was read by the secretary to the committee.

Dr. **CHARLES A MERCIER**, a member of the committee, moved the adoption of the report and emphasised that part of it which recommended its publication in full in the *Journal of Mental Science*. He paid a high tribute to Dr. Wilson for his laborious collation of the details and the lucid presentment of them.

Mr. **JAMES STEWART** (Clifton) seconded the motion for adoption and it was unanimously carried.

Dr. L. C. **BRUCE** read a paper by himself and Dr. A. S. M. **PEEBLES** (Perth Asylum), entitled "Quantitative and Qualitative Leucocyte Observations in Various Forms of Insanity." The contribution showed exhaustive research and contained several significant and suggestive points. One of them was that the large lymphocyte which, according to Hutchison, is not usual in normal blood in any considerable quantity, was commonly present in many cases of pure mental disorder. Moreover, if a person were immunised against a bacterial toxin it was found that those cells became definitely phagocytic. The eosinophile cells, ordinarily about 2 or 3 per cent., rose to 50 per cent. in some abnormal mental states.—Dr. **ROBERT JONES** spoke in flattering terms of the energy shown by Dr. Bruce and Dr. Peebles. He referred to drugs, such as pilocarpine, cinnamate of sodium, and camphor, which increased the lymphocytes in the blood.—Dr. **BRUCE**, in his reply, said that Dr. Peebles and himself had tried the drugs referred to by Dr. Jones except camphor and found that though they increased the lymphocytes that effect was not noticed in connexion with the polymorphonuclears. The leucocyte investigation had a practical application in the assistance which it gave to a correct prognosis.

Dr. W. C. **SULLIVAN** (H.M. Prison, Pentonville) read a lengthy contribution entitled "A Statistical Note on the

Social Causes of Alcoholism." He pointed out that the bulk of the social evil wrought by intemperance was due to chronic alcoholic poisoning, not to simple drunkenness. Thus, suicide, crime, insanity, and racial degeneration—in so far as they were caused by drink—depended on chronic alcoholism. But the sort of drinking which led to casual drunkenness might be entirely different from that which led to chronic intoxication. Drunkenness in its simple form was the result, mainly, of convivial drinking, of the drinking that went with conditions of relative luxury; it was generally intermittent and did not tend much towards chronic alcoholism. It was quite different with the sort of drinking which might be termed industrial drinking, the drinking that went with bad hygienic conditions, overcrowding, insufficient or unattractive food, overwork, and so on. It was characteristic of this form of drinking that it went on during working hours and that it was more or less in substitution of food. It might not cause drunkenness except indirectly, but it inevitably led to chronic alcoholism. The difference between these two sorts of drinking explained the fact that the distribution of drunkenness in England differed widely from the distribution of alcoholism, alcoholic suicide, crime, and insanity. This contrast was demonstrated by means of coloured maps which showed that the counties ranking highest in the list of drunkenness ranked low in alcoholism. The same result was brought out more clearly by comparing drunkenness and alcoholism in large composite areas representing special industrial conditions. Thus it was shown that the prosperous mining districts, where there was little industrial but much convivial drinking, were much more drunken but much less alcoholic than any other part of the country—they were even a little less alcoholic than the agricultural counties but nearly five times as drunken. In the manufacturing towns, where the industrial conditions were less favourable, there was much alcoholism; and in the seaports, where these conditions were at their worst, alcoholism, alcoholic suicide, and crime reached their highest development. In these towns the alcoholism was accompanied by much drunkenness, though the drunkenness was not the cause of the alcoholism but both were effects of a common cause in the industrial conditions. Statistics of drunkenness were therefore of no value as a measure of alcoholism. From a social point of view convivial drunkenness was at once much less important and much easier to check than was industrial alcoholism. The remedy for the latter form of drinking was to raise the standard of living and something might also be done by restricting the facilities for obtaining alcohol during working hours by providing hygienic substitutes and by sane and temperate teaching as to the proper use and limitations of alcoholic liquors.—Mr. STEWART, who said he had been interested in the subject for 25 years, urged that great care should be used in differentiating between chronic alcoholism, drunkenness, and inebriety, and Dr. Sullivan, in one part of his paper, had referred to the causes of inebriety instead of the causes of drunkenness. The consequence of this confusion of terms was that a large number of drunken persons were looked upon as cases of disease and when their vicious habits were abandoned it was considered that they had been cured of the disease of inebriety. That somewhat accounted for the vaunted efficacy of "gold cures," "atropine cures," and the like. Dr. Sullivan's comparison between the amount of chronic alcoholism in certain districts and the number of attempts at suicide was of great value because many persons would glibly declare that all who suffered from chronic alcoholism had brain disease, a statement he dissented from. Only the presence of brain disease would justify the term "inebriety." Dr. Sullivan's classification into "luxury drinking" and "misery drinking" was very happy and would help to account for many cases which came under notice. In a series of 200 cases he found 134 had been due to "misery drinking." Mr. Stewart proceeded to give his reasons to account for the large number of such cases among women and concluded by pointing out the fallacy underlying much of the motive for indulging in the habit.—Dr. C. A. MERCIER was not prepared to discuss the paper at once but thought that Dr. Sullivan's classifications were well worthy of consideration and that they must profoundly affect a person's manner of regarding the subject.—Mr. H. F. HAYES NEWINGTON pointed out that in discussing the subject the social and psychological aspects overshadowed a very important point which was often quite forgotten—namely, the poor quality of the liquid consumed under various names. The question could not be adequately discussed without that being taken into consideration. It was of little use to speak of Parliamentary control or the reduction of licences while the distiller was allowed to continue to poison His Majesty's subjects. A large proportion of distillers used scarcely any malt and much of the whisky consumed was cyder and spirit. It had recently been stated that there was no test for brandy.—Dr. DAVID YELLOWLEES said he appreciated the distinction between convivial drinking and misery drinking but it by no means covered the ground. A large class of drunkards needed neither the excuses of conviviality nor of misery but drank because they liked to. He asked what "chronic alcoholism" meant. His own feeling was that it meant degeneration of the whole organism, brain included, by alcohol, but it was obviously not the meaning of Dr. Sullivan. He pleaded for a clear definition of the terms used in speaking of alcoholic indulgence.—Dr. G. F. BLANDFORD and Dr. R. W. BRANTHWAITE continued the debate, the latter stating that though he had an experience of 22 years in that department he did not yet know which was a drunkard and which was a chronic alcoholic.—Dr. GEORGE H. SAVAGE thought knowledge on the subject was largely increased by statistics and heartily seconded the remarks of Mr. Hayes Newington. The cases which came under the notice of the alienist were the recurrent ones—cases of recurrent mania or recurrent mental disorder. Those people did not drink because they were miserable but because it was the stage of the mental disorder through which they were passing.—Dr. ROBERT JONES said the view of many was that the chronic alcoholic or drunken person succumbed last in the brain, whereas in alcoholic insanity the brain suffered first. It was a case of *locus resistentiæ minoris*.—Dr. SULLIVAN, in reply, said he regarded as inebriety the act and tendency, whereas chronic alcoholism was the effect. During a large experience at Liverpool he knew of only three "blacklisters" in whose history there had not been one or more attempts at suicide.

Dr. J. KENNEDY WILL read notes on a case of Combined Spinal Degeneration with Unusual Mental Symptoms and illustrated the paper by means of microscopic sections of the cord.—Dr. W. B. STODDART discussed the paper.—The company afterwards dined at the Café Monico.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Cases and Specimens.

A meeting of this society was held on May 18th, Professor JOHN CHIENE, the President, being in the chair.

Dr. T. M. BURN-MURDOCH exhibited the following cases: 1. A child, aged ten months, who was admitted to hospital suffering from Infantile Scurvy. This was a very unusual condition and, in fact, was the first case of the kind which had been seen by any of the medical officers of the institution. The child had been fed for nine months on sterilised milk obtained from the Leith corporation depot. The legs were painful when moved and the child lay flaccid and limp with the legs everted. On admission there was a brawny swelling at the lower part of the left femur and at present there was a similarly situated mass on the right thigh. The left arm was also much affected and was kept constantly straight out from the body, there being a subperiosteal hæmorrhage over the humerus. The bowels were constipated and the motions were streaked with blood. The vaccination scars became red though the operation had been performed six months previously. There were traces of blood in the urine and the gums were slightly congested though not bleeding. 2 A girl with a well-defined Rheumatic History and with a Cardiac Lesion who showed well the presence of rheumatic nodules over the knuckles, wrists, ankles, tendons, spine, &c. 3. A female child, aged six years, with a marked Ataxic Gait. She was first admitted to the hospital in July, 1902, suffering from inability to walk and with squint, which conditions had persisted for two years. At that time she was very nervous and was constantly falling, her speech was slow, and there were choreic movements of the hands, though her intelligence was up to the normal standard. There was improvement after this for a time and the child attended school. Her present *condition showed internal strabismus, slurred speech*, constant muscular fibrillary twitchings, and no dragging of the feet; the condition was probably due to a tumour in the cerebellar tissue. 4. A boy, admitted for very Intense Paroxysmal Headache. There were chronic fibrosis of the left lung and double optic neuritis. These were the only symptoms and the case was probably one of cerebral tumour.

Mr. Harold J. Stiles showed:—1. A child with Congenital Elevation of the Scapula. The left shoulder was seen to be deformed and its movement was interfered with; the shoulder was higher on the *left* side and not so broad as the right. Abduction of the arm from the shoulder was rendered impossible on account of a mass of bone which grew from the upper border of the scapula and which became wedged against the transverse processes of the vertebræ. The treatment was to divide this bony mass from its attachment to the scapula. 2. A boy, aged 11 years, after Cuneiform Osteotomy of the Femur for Coxa Vara. The lameness came on when he was four years of age with little or no pain and free movement of the right hip except that of abduction, and the limb grew shorter. The pelvis was tilted on the deformed side and there was fixed adduction of the hip to an angle of 35°; the trochanter on the right side was elevated one and a half inches. There were no history of disease and no wasting of the limb. All the signs were present of a simple bending down of the neck of the femur. At the operation a wedge of bone was removed from below the root of the trochanter and the limb was fixed in an abducted position after division of the adductor muscles for three months. At the present time there was no tilting of the anterior superior spine. 3. A girl, aged nine years, from Shetland, after an operation for an unusually large Hydatid Cyst of the Liver. The heart was displaced and the tumour reached down an inch below the umbilicus. It resembled a hydronephrosis but the thrill was very well marked and the hydatid fremitus was present. A vertical incision was made through the middle of the right rectus muscle and on opening the cyst about a gallon of fluid escaped. The cyst wall at once began to separate from the liver and was extracted in two pieces. There was one daughter cyst of the size of a bantam's egg. The opening in the liver was stitched to the peritoneum and a large tube was introduced. 4. A child, aged two and a half years, after excision of a large Sarcoma of the Left Kidney. The operation was performed nearly four months ago. For three months previous to this the swelling had been noticed and the child made no complaint of pain. The tumour extended one inch below and one inch to the left of the umbilicus. A long incision was made below the left costal margins from the erector spinæ to the front dividing the peritoneum and the tumour was shelled out. Some enlarged retroperitoneal glands were felt but at present there was no obvious recurrence of the disease. 5. A child after Arthrodesis of the Ankle and Knee for Infantile Paralysis. The paralysis was very severe, involving at first both lower extremities as well as the right arm. Recovery, however, was almost complete with the exception of the right leg, of which only the psoas muscle retained its activity. The ankle was fixed by a long nail driven right up into the tibia and now both ankle and *knee joints were still. 6. A girl after a second operation for* Ununited Fracture of the Humerus. At the first operation an aluminium plate fixed by four screws was inserted, but as the wound was septic union did not take place between the broken ends of the bone. Four weeks ago the same operation was again performed as the wound was then aseptic. There was still a small sinus present but a good deal of new bone had been thrown out.

Dr. John Thomson exhibited:—1. A case of Congenital Cerebellar Ataxia of the type described by Dr. F. E. Batten. The boy was aged four and a half *years and presented* marked bilateral nystagmus of a conjugate character and lateral head nodding. The latter conditions had been present since early infancy. A year ago the ataxic gait was well marked; he spread his legs apart in walking and frequently fell backwards. It was not a hereditary condition. The knee-jerks as well as the other reflexes and organic reflexes were normal. The child was improving to a slight extent. 2. A girl, eight years of age, with a peculiar Congenital Deformity of the frontal, nasal, and superior maxillary bones. The patient was an imbecile child of a mentally defective woman. The frontal bone was divided into two by a wide sulcus and the nose was very broad and possessed a wide median groove. The eyes were *very far* apart; the upper jaw was atrophied and the palate was dwarfed, as was especially the case with the premaxillary bone. The case was one of an attempt at the double formation of a head above the nose.

Mr. Stiles and Dr. Thomson exhibited three cases of Congenital Hypertrophy of the Pylorus after Operation. The first case was operated upon two years ago, when he was only four and a half weeks old and weighed a little over six pounds. He had vomited all his food during the preceding fortnight and there was marked constipation. The emesis became more and more severe and the stomach became greatly distended. Loreta's operation of forcibly stretching the pylorus was performed. This was a simple procedure, the stomach being opened near the pylorus and a pair of forceps being passed into the pyloric orifice and opened up, though Mr. Stiles had found a three-bladed tracheal dilator more useful. In this case the vomiting ceased at once and the child rapidly improved. The boy was now two years old. The second case was that of a child now 13½ months old. The operation was performed on June 16th, 1903, when the infant was 10½ weeks old. When five weeks old the weight was ten pounds. At this period, however, vomiting, constipation, and emaciation commenced and when the operation was performed the child weighed only seven pounds. Loreta's operation as above described was performed and for two weeks the vomiting ceased. It then returned, however, and as the child was obviously seriously ill a second operation was accomplished three weeks after the first. A posterior gastro-enterostomy was performed and at once the child commenced to improve. In future Mr. Stiles would always perform the latter operation for this condition as it simplified the after-treatment very much and the child could be fed at once. In Loreta's operation to be effectual the peritoneal coat must be ruptured by stretching and then this had to be sutured. They could never tell how much fibrous tissue might be the result of such procedure. The third case was that of a child now three and a half months old. The operation of posterior gastro-enterostomy was performed on April 1st, 1904, when the child weighed six pounds. At the present moment the weight was ten pounds. Mr. Stiles uttered a word *of warning against the use of* carbolic poultices in the case of young children.

Dr. J. S. Fowler showed: 1. A case of Dwarfed Growth in a child eight and a half years of age, exhibiting some of the symptoms of cretinism and probably due to thyroid inadequacy (myxœdema fruste). The child was 37 inches high or 10 or 11 inches shorter than he ought to have been, or in other words, his height corresponded to that of a child three and a half years of age. All the members of his family were short of stature, probably the result of rickets. The boy did *not walk until four years of age* and since then he had not grown in height. The face was heavy and swollen in appearance, as was also the neck, and the abdomen was large. Skiagrams showed that the ossification of the bones corresponded to that of a child of the age of three years. 2. A case of General Spastic Rigidity with a Low Grade of Idiocy and very Severe Rachitic Deformity. The child was now about five years of age; the birth was natural and three days subsequently fits began to occur. Development had never proceeded; the child cried constantly, sucked the tongue, and rolled the head. These were some of the symptoms of microcephalus, but Dr. Fowler did not think this was a pure case of that affection but rather that there had been an extensive cortical hæmorrhage which had interfered with the growth of the child's brain.

Dr. Drummond exhibited a case of Microcephalus. The child was nine months old and at the age of three months fits commenced. They were very numerous, eight or nine per diem. Under the action of bromide of potassium and chloral the fits had nearly ceased. The head was of the size of that of a child aged six months and the anterior fontanelle had completely closed.

Mr. E. W. Scott Carmichael showed a boy with a Congenital Malformation of the Bones of the Right Forearm. The third metacarpal bone with the corresponding phalanges were absent from the right hand.

The following card specimens and photographs were also shown:—

Dr. Burn-Murdoch: Photographs of a remarkably interesting case of deformity, Double Congenital Dislocation of the Hip, and a rare condition of both knees, the External Condyles of the Femora *being Undeveloped* and the Patellæ being Absent.

Mr. Stiles: (1) A small Round-celled Sarcoma of the

Upper Half of the Femur: Disarticulation at the Hip; (2) a large Hydrocephalic Head; (3) a Hydatid Cyst of the Liver; (4) a Gold Brooch removed from the Œsophagus of an Infant by Median Œsophagotomy; and (5) a large Sarcoma of the Kidney and microscopical specimen.

Dr. Fowler: Specimens and drawings of Blood from a Mixed-celled Leucocythæmia in a child—excess of large lymphocytes and myelocytes.

Mr. Scott Carmichael: (1) Congenital Absence of the First and Second Parts of the Rectum, with sac-like dilatation of the descending and sigmoid colon; (2) Necrosis of the Os Calcis, the result of a septic wound of the foot; and (3) Recent Ileo colic Intussusception.

Dr. Thomson: (1) Bones of the Lower Limb from a case of Infantile Scurvy (Barlow's Disease); (2) Diplococci from a case of Posterior Basic Meningitis; and (3) photographs and drawing of Rheumatic Nodules in various positions.

West London Medico-Chirurgical Society.—A meeting of this society was held on May 6th, Dr. Seymour Taylor, the President, being in the chair.—Mr. L. A. Bidwell read a paper on Chronic Pancreatitis. Two types of the malady were described: (1) the interlobular variety, the islands of Langerhans being unaffected except in the latest stage; and (2) inter-acinar pancreatitis in which there were cell infiltration and fibrous tissue formation within the lobules and inside the islands of Langerhans. The second type was the less frequent variety and was not commonly associated with duct obstruction but was accompanied by glycosuria. The interlobular variety was met with in association with obstruction of the pancreatic duct by pancreatic calculi, biliary calculi impacted in the ampulla of Vater, cancer of the bile papilla, or stenosis of the opening by inflammatory changes originating either in the bile duct or in the duodenum. In cases of impacted gall-stone there was a considerable amount of cholangitis set up which, owing to the communication between the bile and pancreatic ducts, spread to the latter duct. Thereafter, there being no outlet for the inflammatory products, the substance of the pancreas became involved in the inflammatory changes and chronic interstitial pancreatitis resulted. This condition might subside completely but on the other hand it might pass on to abscess formation with secondary suppuration of lymphatic glands. The symptoms resembled those exhibited by the slighter cases of subacute pancreatitis. The onset was usually gradual but an acute attack of pain in the epigastrium resembling that of gall-stone colic and followed by jaundice might usher in the attack. Loss of flesh and strength were prominent features. The emaciation and weakness steadily increased and a fatal result if no operation were undertaken was almost certain. These cases had to be distinguished from gall-stones, cancer of the head of the pancreas, cancer of the liver and ducts, and cancer of the stomach, and the points of differential diagnosis were discussed. The treatment recommended was laparotomy. A certain number of cases had recovered after simple palpation of the pancreas, but many surgeons, amongst whom was Mr. A. W. Mayo Robson, advised that the gall-bladder should be drained in all cases. Removal of any stone found in the ampulla of Vater was also necessary. The narration of four cases of chronic pancreatitis which had come under Mr. Bidwell's own observation concluded the paper.—The President referred to the diagnostic value of rigors in cases of jaundice due to gall-stone obstruction.—Mr. W. McAdam Eccles had had the opportunity of observing two of the cases referred to by Mr. Bidwell. A point of great interest was the occurrence of clear unclouded mucus in the gall-bladder. In neither case was there any sign of calculi in the biliary ducts. He felt sure that in some instances in which a patient suffered from what appeared to be biliary colic and showed evidence of sugar in the urine the pancreas was the seat of the real lesion.—Mr. E. Percy Paton considered that in two of Mr. Bidwell's cases there was a good deal of uncertainty as to the diagnosis and it seemed to him that in both of the cases the true nature of the disease might have been carcinoma.—Mr. Bidwell replied.—Mr. Eccles read a paper on Lessons from a Year's Fatalities. In all, 19 cases were referred to and in all death was due to lesions of the head or trunk, a fact which illustrated one of the advances of modern surgery—namely, that operations on the extremities were fraught with but little danger provided that sepsis was excluded. No less than 14 of the fatalities were due to abdominal lesions. Of the other five cases one was due to fracture of the base of the skull, one to hæmorrhage into the mid-dorsal region of the spinal cord, and one to fracture of the ribs with injury to the heart wall. This last case was specially interesting. The patient, a boy, aged 14 years, was crushed between two vans. On admission he was collapsed, livid, with very laboured respiration and much frothing of mucus in the larynx and mouth. Examination showed fracture and depression of the fourth, fifth, and sixth left rib cartilages. A grave prognosis was given but the boy made steady improvement. 16 days after the accident, while sitting up in bed, he died suddenly. Post-mortem examination revealed, in addition to the fractures above noted, bulging and perforation of the left ventricular wall in a position immediately under the fractured fifth rib. There had apparently been a partial laceration of the ventricle and the wall had gradually thinned and eventually ruptured, causing the fatal issue. The other two fatalities were due to carcinoma of the mammary gland and in both pulmonary infection was the immediate cause of death. Of the 14 abdominal cases death was due to abdominal tubercle, gastric hæmorrhage, hæmorrhage from the hepatic artery in the floor of a duodenal ulcer, carcinoma of the sigmoid flexure, internal strangulation by a band, strangulated femoral hernia, and multiple hepatic abscesses in one instance each, to intussusception in three cases, and to lesions of the vermiform appendix in four cases. A study of these fatalities from appendicitis tended to confirm Mr. Eccles in his view that in all cases in which there was strong suspicion that the appendix had been inflamed it was safer to remove it than to wait for subsequent attacks, any one of which might prove disastrous.—Mr. Paton endorsed the opinion expressed by Mr. Eccles as to the advisability of removing the appendix after one clear attack of inflammation of that organ. He had seen most satisfactory results from operation in tuberculous peritonitis similar to the case quoted, in which there had been large masses in the abdomen, together with very little peritoneal effusion.—Mr. F. G. Lloyd was unable to agree with Mr. Eccles's conclusion as to the necessity for operation in all cases of appendicitis after a first attack.

British Laryngological, Rhinological, and Otological Association.—A meeting of this association was held on May 13th, Mr. John Bark, the President, being in the chair.—The President said that the association had sustained a great loss through the death of Sir Philip C. Smyly and it was resolved that a letter of condolence should be sent to Lady Smyly and the family.—A letter was read from the Laryngological Society of London inviting coöperation in the appropriate celebration of the 100th birthday in March, 1905, of the inventor of the laryngoscope, Señor Manuel Garcia.—It was resolved that a special council meeting should be held to consider this matter.—Dr. W. H. Kelson showed a case of Post-nasal Casts. The patient, a man, aged 36 years, had for years suffered from post-nasal catarrh. About once a week a tough fibrinous disc of the size of a shilling formed in the region of Luschka's tonsil. It became loose after three or four days and the patient was able to expectorate it. Scraping, galvano-cautery, and caustics had been tried but the disc reappeared.—Dr. J. Dundas Grant said that this case resembled Thornwald's disease. He advised trans-illumination, a bacteriological examination of the crusts, and the use of his new sniffing nasal douche.—Dr. V. H. Wyatt Wingrave said that as all lymphoid structures had disappeared he looked upon the case as one of atrophic pharyngitis. He advised diminution of the enlarged turbinals.—The President advised the trial of von Troltsch's method of gargling and washing out the naso-pharynx.—Dr. Kelson also showed a case of Epithelioma of the Larynx and Œsophagus in a single woman, aged 31 years.—The President said that last year he had shown a case of epithelioma in the œsophagus in a still younger instance—namely, a woman, aged 28 years.—Mr. Mayo Collier read the notes of a case of Acute Abscess of the Thyroid Body after Influenza. The patient was admitted into the North-West London Hospital on April 18th with a large, pulsating swelling on the left side of the neck. The trachea and attached structures were all displaced to the right side. Dyspnœa and cyanosis were present and the expectoration was blood stained. An ice-bag was applied. An operation was performed by Mr.

J. Jackson Clarke and Mr. G. Templeton. An incision about three inches long was made in the middle line and the tumour was partially isolated. There was severe hæmorrhage from engorged veins during this stage of the operation and the patient began to show signs of asphyxia. The trachea was opened low down in the neck and a tube was introduced. Artificial respiration, injection of strychnine, and ammonia to the nostrils had no effect, the patient never breathing again. At the necropsy it was found that the swelling was limited to the left lobe of the thyroid. When opened it was found to contain a quantity of thick, chocolate-coloured, extremely offensive pus. The swelling was adherent to the carotid sheath. The rings of the trachea showed no signs of atrophy from pressure and both recurrent laryngeal nerves were apparently sound. The heart muscle and valves were normal; the right side was distended with clot. The lungs were very œdematous. The bronchi were filled with frothy fluid. The other organs were apparently normal.—Dr. Dundas Grant mentioned a similar case under his care in which death took place very suddenly.—*Dr. J. Lumsden showed a Nasal Dilator* for continuous dilatation of the anterior nares in cases of nasal obstruction when due to swelling of the mucous membrane covering the nasal bones. The benefits which he had found to result from the use of it by those who complained of stuffiness in the nose were (1) that it allowed the nose thoroughly to be cleared from discharge by sniffing air backwards; and (2) that it allowed nasal respiration to be carried on comfortably while it was in place. The instrument was made by Messrs. Arnold. It was meant to be worn at night chiefly.—Dr. Andrew Wylie stated that he tried this dilator and had found that it afforded the patient great relief.—Dr. Wyatt Wingrave deprecated the constant stretching of the alæ nasi and advocated the employment of an india-rubber tube.—Dr. W. Jobson Horne spoke favourably of small pieces of cotton-wool tucked up into the recess of the vestibule of the nose.—Dr. J. Sim Wallace, in resuming the adjourned discussion on Mr. Mayo Collier's paper on Latent or Intermittent Nasal Obstruction, said that the nose was not only a respiratory organ but a perspiratory organ also, and if the function of perspiration was interfered with or unduly taxed various deleterious effects were certain to be brought about.—Dr. Wyatt Wingrave maintained that there was an intimate relation between nasal obstruction and the onset of puberty and even between some obstructions of the nose and menstruation.—Dr. L. H. Pegler, Mr. E. Dennis Vinrace, Mr. Fox, and Mr. Barwell also made some remarks.

British Gynæcological Society.—A meeting of this society was held on May 12th, Mr. John W. Taylor, the President, being in the chair.—*The President exhibited* the following specimens and read notes of the cases. 1. A Loop of Semi-Gangrenous Intestine successfully removed from a patient 77 years of age with its solid undigested contents; it was taken from a hernia in the cicatrix of an abdominal section performed 23 years previously (a partial hysterectomy for fibroids); the hernia had been strangulated for 24 hours. 2. A Cyst of the Broad Ligament which contained upwards of 30 ounces of fluid successfully enucleated from the vagina.—*Dr. Macnaughton-Jones then gave a demonstration of the Method* of Moulding Pessaries from the Celluloid Rings recommended by Schultze, pointing out that these rings were lighter and stronger than any others and always retained the shape into which they were moulded.—Dr. Heywood Smith then opened the postponed discussion of Dr. Macnaughton-Jones's paper on the Dangers of Pessaries. He attributed much of the evil of pessary treatment to the mistaken idea that the application of a pessary could cure a retroversion and to the introduction of pessaries without previous correction of any existing displacement; he could not concur in the view that reposition by the sound should be altogether abandoned.—Dr. C. H. F. Routh exhibited the combination of a Hodge pessary with a ring and hollow stem pessary which he had found most useful, especially in curing sterility; he had not experienced any evil results.—Dr. Herbert Snow said that he had come to the conclusion that pessaries should not be applied for versions or flexions but only to relieve pain or to prevent prolapse; the elastic ring pessary would do this and was harmless.—Dr. R. H. Hodgson said that in 20 years' experience he had never seen any evil from a pessary properly introduced and not neglected and he was sorry to hear stem pessaries condemned as in a number of cases he had known them to relieve pain that had been of years' duration.—*Mr. E. Stanmore* Bishop expressed his entire belief in the lever action of pessaries but said that he thought that in their use a great distinction should be drawn between flexion, version, and prolapse; in flexions he considered that they could do no good and were likely to do harm. The worst cases to deal with were those of procidentia which in his experience was always accompanied by rectocele and cystocele; if operation was declined it became necessary to resort to some form of Pott's pessary, of which he exhibited one introduced in Manchester by *Dr. A. Donald*, but these all required the use of a belt which was a great objection to them.—The President said that the dangers of the continued use of pessaries seemed to him twofold—namely, (1) the development of pelvic disease either by the rekindling of old inflammation or by infection from the husband, alienated by the presence of the instrument, or by infection directly due to the presence of the pessary; and (2) the effects of stretching, for the pessary not only held up the cervix so that the fundus fell forwards but it also acted injuriously by stretching the sacro-uterine ligaments. *He had made extensive trial of celluloid* rings but he had not found them satisfactory and, like Dr. Macnaughton Jones, had reason to prefer the Smith-Hodge or S pessary to the figure of 8 pessary.

South-West London Medical Society.—A meeting of this society was held on May 11th at Bolingbroke Hospital, Mr. E. F. White, the President, being in the chair.—Dr. E Furniss Potter read a paper entitled "Some Observations on the Treatment of Adenoids." In reviewing the indications for operation Dr. Potter said that cases might be divided into two classes: (1) those in which the objective signs were so obvious that no one would question the desirability of removal; and (2) those in which the signs and symptoms were comparatively slight, such as when a child was beginning to be deaf or was frequently suffering from colds in the head or spoke with a "nosy" tone of voice. In the daytime the child might not present the appearance of a mouth-breather and when asleep he might not snore and might keep his mouth firmly closed, yet on examination a small quantity of adenoid tissue might be found in the naso-pharynx. In cases where there was any appreciable defect in hearing or where stuffiness in the nose was chronic an operation was indicated. In cases where free intervals alternated with periods of obstruction it was more difficult to decide. As regards the anæsthetic Dr. Potter advised nitrous oxide gas and ether. Under nitrous oxide alone the duration of the anæsthesia was too short. With respect to instruments only two need be mentioned—namely, forceps of various shapes and the curette (Gottstein). The latter was excellent for removing a central clump but was not so suitable where growths were scattered or in close proximity to the Eustachian cartilages. In these cases the forceps were preferable.

Reviews and Notices of Books.

La Maladie du Sommeil: Rapport par la Mission envoyée en Afrique Occidentale Portugaise. (Report of the Commission on Sleeping Sickness in Portuguese West Africa.) By ANNIBAL BETTENCOURT, AYRES KOPKE, GOMES DE REZENDE, and CORREA MENDES. Lisbon: Imprimerie de Libanio da Silva. 1903. With plates. Pp. 280.

THIS report was presented to the Minister of the Marine and of the Colonies by the members of the commission sent to investigate the subject of sleeping sickness in Portuguese West Africa. The work commences with a historical survey of this fatal disease which became recognised as a well-characterised morbid entity so far back as the commencement of the last century, when in 1803 Winterbottom showed its existence amongst the slaves in the Bay of Benin. Next, in 1840, a missionary, Clark, described it under the name of "hydropisie narcotique" on the Gold Coast and Sierra Leone. In the third quarter of the century a very accurate description of the symptoms of the disease was given by F. W. Davis, an English naval surgeon, and he mentions that it was held to be brought about by smoking the narcotic weed *dyambo* and by drinking bad palm wine. It is interesting to note that this authority held that some of the cases might be due to chronic meningitis or encephalitis. The historical references are next brought down to recent times, whilst the geographical range of the disease is indicated.

The mission undertook its labours in order to study sleeping sickness as it affects the province of Angola. It started from Loanda and the extensive itinerary shows what large portions of the country were visited. It would seem that before the year 1871 the malady had not attracted much attention. Although it was disseminated throughout the province, excepting the portion south of the fourteenth degree of latitude, yet its intensity and frequency were not the same for all regions. Loanda was found to be the locality most intensely affected. The malady after the year 1877 made marked strides and during the last three years it has attained the highest degree of intensity.

Regarding the predisposing causes of the disease, the authors find that it takes root mostly where the climatic conditions are hot and moist and where the vegetation is very abundant. It was found to be the least disseminated at Ambaca, where the vegetation was scanty and irrigation was but little carried on, and at Pungo-Andongo, a stony and elevated region, not subjected to great heat and with a smaller amount of humidity. The disease attacks both sexes. The opinion is often held that men rather than women are attacked but this is due to the fact that in the localities where this view is taken the men largely predominate. Again, at Cuanza the opposite holds good, for here the affection would seem to be more prevalent amongst women, this really being due to the fact that the men have emigrated to other regions whilst the women remain there. The truth is that the disease shows no preference for either sex. All ages are attacked; in early infancy and above 60 years it is rare. Adults show the largest number of cases, then adolescents, and next children of from five to ten years of age. The negro race is principally attacked. The affection is far from rare amongst half-castes; amongst whites it is excessively rare—in fact, the authors do not believe that the latter are ever attacked. This, however, as shown by recent cases reported in medical literature, is not the case.

As regards the environment of the inhabitants, the negro lives in cottages, sleeping either on mats or on raised platforms. The cottages are divided into two chambers—the one near the entrance for domestic animals and the other, separated by a bamboo palisade and of but small dimensions, for the whole family. The cottages are kept clean internally but the excreta are thrown on the ground near them. The food is dried fish and a flour of maize or of manioc. Meat is also taken, preferably in a state of putrefaction. Water is drunk which is often of the most insanitary description and alcohol is taken to an excessive degree. Tobacco is much smoked, often from a pipe common to many of the inhabitants.

The authors do not agree with Corre that the disease is hereditary. As regards contagion, in the region investigated this idea is firmly held—it is supposed to be transmitted by the clothes and the saliva. The authors of the report are in agreement with this belief and detail their reasons for so thinking. They next proceed to discuss more minutely the various hypotheses which are held regarding sleeping sickness and they conclude from their investigations that the lymphatic system is affected first and that subsequently occurs the lesion of the nervous system. The latter, however, ensues at a period separated by a long interval from the invasion of the lymphatic system and thus the long duration of the disease is explained.

A review is next made of the various micro-organisms that have been held to cause the disease. Following this is an excellent chapter on the symptomatology which is illustrated by highly characteristic plates and we next find the post-mortem results minutely recorded. Regarding treatment the authors appear to have tried many remedies; they recommend salicylate of sodium for the febrile attacks. Arsenic has a certain value when given with quinine, kola, and cocoa. Where the blood contained the filaria perstans oil of male fern was prescribed but without any effect. Neither lumbar puncture nor the injection of a 1 per cent. solution of lysol into the subarachnoid space caused any amelioration. Finally, the authors employed a serum obtained by the inoculation of asses with cultures of a streptococcus which was isolated by them and which they believed to be specific but the result was valueless.

In the chapter on the bacteriological researches with regard to sleeping sickness the authors describe the characters of a diplo-streptococcus discovered by them in the subarachnoid fluid. This organism they hold to be identical with the one described by Castellani independently. These results will, of course, require reconsideration in view of the recent discovery of a trypanosome in cases of this disease.

The conclusions which are arrived at are: that the malady is "une méningo-encéphalo-myélite diffuse," affecting chiefly the higher segments of the cerebro-spinal axis; that it is an infectious malady; and that the micro-organism described by them has been found in nearly all the cases investigated. With regard to prophylaxis they hold that every patient should be at once isolated, and the habitations where cases have occurred must be rigorously disinfected or burnt. Separate eating and drinking utensils should be provided for the inhabitants of any infected region. Abuse of alcohol and excessive fatigue should be avoided. Masters should not engage servants from an infected region. Finally, they recommend inoculation with the above-mentioned serum which was found to give good results in the animals experimented on.

The Medical Inspection of School Children. By W. LESLIE MACKENZIE, M.A., M.D. Aberd., Medical Inspector of the Local Government Board for Scotland; assisted by EDWIN MATTHEW, M.A. Aberd., M.B., C.M. Edin., Assistant Physician to the Leith Hospital. Edinburgh and Glasgow: William Hodge and Co. 1904. Pp. 455. Price 10*s.* 6*d.*

THIS volume is intended for the use of medical officers of schools and medical officers of health, as well as school managers and teachers, and cannot fail to assist in correlating the medical inspection of children with school management and teaching. The book has been written as a sequel to the report of the Royal Commission on Physical Training (Scotland) which definitely recommended that "provision be made for regular inspection of the children in all schools." With this recommendation we are heartily in accord and trust that it will be carried into effect by the Government. This will necessitate the appointment of many medical inspectors trained for this particular service of the State and for such the work under review forms a valuable text-book, containing much information on the medical inspection of children as well as on school organisation and the powers of educational authorities. To insure useful results from the medical inspection proposed it is essential that there should be a certain amount of knowledge and mutual understanding on many matters concerning both the inspectors and those engaged in education in the schools, so that reports made to the authorities may be understood and acted on. On pp. 255–377 the writers deal with the methods of examination and conditions of defect commonly found in the teeth, nose, ears, eyes, lungs, and so forth, as well as with the infectious diseases of childhood; the descriptions given are rather brief, being intended only for the instruction of medical men engaged in the duties of inspection who may be supposed already to have acquired skill and experience in these departments of clinical work, but they will serve a useful purpose in supplying information to school managers and teachers when acting on reports as to the maladies of childhood which interfere with school life.

In the first part of the book, speaking of administrative difficulties that may arise, Dr. Mackenzie refers to parental objections and says that "when a system of medical inspection is once fully organised difficulties at present in the way will cease to exist." This raises an important question that is sure to be put forward when the matter comes before Parliament and one which it is the duty of the profession to meet fairly. It must be seen that a medical examination of children compulsorily attending school, if it is not to be followed by means for the relief of maladies or defects through medical treatment, may not altogether unreasonably give offence to some parents. The Commission instituted an examination of 1250 children in Scotland and we are told (p. 351) that in Edinburgh among 600 children "no case of hernia was discovered, although a very stringent examination was made of 100 girls and 200 boys, and a general examination in the others." Headings—"Hernia—Umbilical, Inguinal, or Femoral"—appear in Schedule A as suggested for adoption; we do not think the investigation of such points necessary among ordinary children attending a day-school. The teachers make a rough classification of the mental abilities of a new pupil by setting the child to work, when his defects are soon observed. What is needed for good school organisation is more accurate diagnosis of brain power and early recognition of any mental or physical disabilities. The principal means of diagnosis presented by the author are anthropometrical; we are surprised to see it stated at p. 65 that "the head measurements could not be regarded as having any direct bearing on physical or mental development or efficiency; but, as pointed out in the Commission's report (p. 24), they afford some data for determining the purity or mixture of races." This is quite contrary to the observations of Dr. Francis Warner and others who have studied the physical indications of mental feebleness and degeneracy, among which "small head" has constantly been observed in a large proportion of the cases. It is said (p. 64) that "measurements of some sort were an obvious necessity, since they alone could give definiteness to simple inspection." This is true in points where measurement is practicable. In the report of a committee of the British Medical Association on schools, 1895, 42 defects in development were defined and recorded in each case where they were seen, 21 "nerve signs" were also looked for, and the two kinds of signs were correlated statistically with the report on mental status and the nutrition of the child; information thus gained afforded valuable evidence used by several Royal Commissions and Parliamentary committees. Some such method might well be incorporated in organising the medical inspection of children.

In the second part of the book Dr. Mackenzie gives much useful information bearing on the practice of medical inspection of children, describing also the effects of environment as already ascertained and the averages of height and weight in relation to age as they have been determined by various observers. The purpose of inspection is defined as "intended first to discover precisely in what way the unfitness is manifested, and second, to indicate how the conditions of school life shall best be adapted to the degree of unfitness." It is in the adaptation of brain training as apart from the instruction of children that specialised medical knowledge and experience in treating mental defects are needed by the school inspector in order that the principles of mental hygiene may be brought to bear on school methods. Hitherto the School Boards that have appointed medical officers have not usually sought their advice as to methods of such training.

The relations of the inspection of children to general social investigation are ably dealt with. It is shown that many factors lead towards the ultimate result which it is desired to achieve through school life—viz , a healthy well-developed adult with full powers of mind and body. The principal factors dealt with are inheritance and hygienic environment. To these might well be added some detailed consideration of the effects of the teaching curriculum on the stability and growth of the brain. Under the heading Pre-natal Nurture the author refers to the heavy mortality of infants in the first month of life which is principally due to premature birth, congenital malformations, and defective conditions of ante-natal origin. It is among the surviving children with some degree of defect that the most difficult pupils are found in the schools. This is a very important aspect of child life which suggests that consideration should be given by the legislature to the advisability of prohibiting the work of women in factories during the later months of pregnancy. Probably hygienic measures which tend to lessen pre natal defectiveness would lower the proportion of adult defectives in our population. Infant mortality falls principally upon the males, while it has been shown that almost all the conditions of congenital defectiveness seen in school children are more frequent among boys than girls and the lesser degrees of developmental defect, such as of the palate, nose, ears, mouth, palpebral fissures, and so on, all possess a significance as stigmata of degeneration and are of anthropological importance in dealing with the problems of childhood. We should like to see these points included among those recorded in the medical inspection of children, because it has been demonstrated that they are correlated with a subnormal brain condition and vitality. Probably the record of minor congenital defects is as good a test as can be obtained of the conditions in any locality predisposing to defectiveness in children, whether inherited from the parents or produced only during the pre-natal period. It was through the record of such points that the marked differences among the nationalities were observed by the committee of the British Medical Association on school children.

The third part of the book is devoted to school anthropometry and contains good illustrations of the apparatus devised by Professor Matthew Hay to whom the Commission intrusted the inspection of children in the Aberdeen schools. The schedule appended for recording each child has numerous headings on matters of social import, to which are added personal appearance and nutrition, height, weight, and certain body measurements, not including the head, together with diseases and gross deformities. Throughout the book it seems to us that the neurological aspect of the child has been subordinated to considerations of hygiene and anthropometry. The book is well printed and will be valued as one of the few standard works that have appeared on this subject.

Ophthalmological Anatomy, with Some Illustrative Cases. By J. HERBERT FISHER, M.B., B.S. Lond., Assistant Surgeon to the Royal London Ophthalmic Hospital (Moorfields). London: Hodder and Stoughton. 1904. Pp. 188. Price 7*s.* 6*d.*

WE are disposed to think that a better title for this work than that which it bears would have been "Cases Illustrating Certain Points of Ophthalmological Anatomy," since the author himself admits in the preface that much that might have been written under the heading of ophthalmological anatomy has not been included and for the omissions refers the reader to the text-books—a proceeding which, whilst it lightens the labour of the author, has the advantage of stimulating the industry of the student. Nevertheless, a good description is given of the intracranial course of the fibres of origin of the optic nerve and of the third, fourth, fifth, and sixth nerves. The account of the olfactory nerve is obviously superfluous and has nothing to do with ophthalmological anatomy. The topographical relations of the skull to the subjacent convolutions and sulci are given with commendable exactitude. Several pages are devoted to a reprint of an article by Dr. Fisher, published in the fourteenth report of the Royal London Ophthalmic Hospital, in which he maintains a theory in opposition to the doctrine generally received that horizontal movements of abduction and adduction are respectively effected by the isolated action of the external and internal recti. This, he says, is a theory with which few anatomists and physiologists are in accord and he proceeds to supply various arguments in favour of his own view that these movements are in each case the result of the action of several muscles, the superior and inferior recti aiding the action of the internal rectus in effecting adduction and the two oblique muscles the action of the external rectus in abduction. The arguments which he advances do not bring conviction to our mind. Mr. Fisher writes a good chapter on the orbit and surrounding air cells. He is of opinion, in which we agree with him, that surgical procedures designed to deal with septic thrombosis of the cavernous sinus must be effected through the eviscerated orbit. The alternative proceedings of reaching the sinus through the maxillary antrum or by the lateral route corresponding to that chosen for the extirpation of the Gasserian ganglion are operations that can only be described, in the language of the elder Guthrie, as long, tedious, difficult, bloody, and dangerous. Mr. Fisher rightly insists on the attention that should be paid from the first to punctured wounds of the orbit, neglect of ordinary surgical antiseptic measures having frequently led to septic meningitis. He makes an original suggestion in regard to the emphysema that is sometimes observed after comparatively slight blows on the nose, emphysema that is limited to the eyelids, nose, and cheeks, and appears to be absent in the retro-ocular tissues. In such cases he has not been able to recognise any fracture of the bones and believes that the blow on the eyelids puts a sudden strain on the internal tendo oculi and thus lacerates the anterior wall of the lacrymal sac to which this ligament is adherent so that on blowing the nose the air is forced into the subcutaneous tissues through the rent in the tear passages. The book will be read with interest by the clinician rather than by the student.

Elements of Water Bacteriology with Special Reference to Sanitary Water Analysis. By SAMUEL CATE PRESCOTT, Assistant Professor of Industrial Biology, and CHARLES EDWARD AMORY WINSLOW, Instructor in Sanitary Bacteriology in the Massachusetts Institute of Technology. London: Chapman and Hall. 1904. Pp. 162. Price 5*s.* 6*d.* net.

THE bacteriological analysis of water has been passing through a period of somewhat severe trial but at last there seems some hope that it may emerge and establish itself on a secure basis as a trustworthy guide to the safety and suitability of a water for domestic purposes. We welcome this little book as a distinct help to this end. In it there are a singular clearness of vision as to the object to be attained and a resolute refusal to be drawn off into side issues which, though of great interest in the study of the flora of a water, are not of practical service for the determination of the sanitary condition of the supply. After a brief period of extravagant anticipation bacteriological analysis fell into an almost equally extravagant disrepute from which it is slowly recovering, thanks to much excellent work done in America and to the patient labours of Houston, Horrocks, and others in England. The difficulties which surround this method of analysis are due to the extreme delicacy of the tests and to the difficulty of determining what interpretation is to be placed on the presence of the ever widening group of colon bacilli and to the lack of any standard methods of analysis. This latter difficulty has been faced, if not met, in America by the appointment of a Committee of Standard Methods, with the result that the quantitative bacteriological analysis of water in that country is on a satisfactory basis as compared with the chaos which prevails in England and Germany. It was owing to the absence of such standard methods, no doubt, that we met with the astounding statements as to the sterility of the London water-supply which were produced for the benefit of the Water Commission. Unfortunately, though a great advance, the standard American methods are more uniform on paper than in practice. Experience shows that the suitability of a culture medium for the growth of organisms is largely modified by the method of sterilisation adopted and the American instructions allow the alternative employment of steam at 100° C. or the autoclave at 110° C. This is, however, of less importance when the analysis is for sanitary purposes than when the bacterial flora is to be studied.

After a preliminary chapter on the various factors which influence the number and variety of organisms in water the quantitative determination of micro-organisms and the interpretation of the results are treated and the broad conclusion is reached that recent contamination will betray itself by the presence of a large number of organisms developing in gelatine in a standard time—48 hours at 21° C. The results are controlled by culture at 37° C. in agar containing lactose and it is shown that normal waters contain few lactose-fermenting germs growing at this temperature. A very brief account of the methods to be employed for the detection of bacillus typhosus and spirillum choleræ is given. Naturally we turn to the chapters on the detection of bacillus coli and the interpretation to be placed on the discovery of this organism in the water examined. On the whole, the chapters dealing with these subjects are good. No attempt is made to dispute the fact that bacillus coli occurs in waters which cannot be condemned but the conclusion is reached that the absence of bacillus coli is certainly evidence of the harmlessness of a water and that when present its numbers form a reasonably close index of the amount of pollution. The solid basis on which these conclusions rest is that of a large number of analyses conducted in a definite manner, which show that an organism having certain characters—the bacillus coli of these authors—can be isolated from small quantities of contaminated waters and not from those which experience has shown to be safe. The significance of the discovery of bacillus enteritidis sporogenes, streptococci and other intestinal bacteria is shortly discussed and the book ends with an appendix giving instructions for the making of standard media. There are a very full bibliography and index.

Lehrbuch der Geburtshilfe. (Text-book of Midwifery.) By F. AHLFELD. Third edition. With 479 illustrations. Leipsic: F. Wilh. Grunow. 1903. Demy 8vo, pp. 757. Price 9 marks.

AS we anticipated on its first appearance, Professor Ahlfeld's "Text-book of Midwifery" has met with a considerable amount of success and a third edition has now been published. There is much in the work to recommend it both to students and teachers. Not only does it put forward the results of the author's own large experience but it also contains the records of a considerable amount of original work carried out by his assistants and others working under his direction. Further than this the book contains a very complete bibliography.

The whole subject is treated in a most thorough and scientific manner, for the author gives not only his own views but does full justice to the work and views of others. It is essential in a text-book primarily intended for students that theories should be critically examined and if necessary rejected. The author of this book does not fail to state his opinions fully and dogmatically upon many debatable questions of practice and these expressions of opinion are of the greatest value since they are those of one well qualified to form a correct judgment. The book is essentially conservative in its general views and some of the more modern methods which have met with a good deal of support from others are regarded with a wholesome scepticism. As instances of this we may mention the employment of Bossi's dilator and the operation of vaginal Cæsarean section, two methods of treatment which have met with enthusiastic support at the hands of at any rate some authors. For the sake of his outspoken views upon these and kindred subjects Professor Ahlfeld's book may be recommended to those obstetricians who are only too readily carried away by their enthusiasm for methods of treatment of as yet unproved value.

LIBRARY TABLE.

Elementary Lectures on Errors of Refraction and their Correction. By HAROLD B. GRIMSDALE, M.B., B.C. Cantab., F.R.C.S.Eng., Assistant Ophthalmic Surgeon to St. George's Hospital, Assistant to the Royal Westminster Ophthalmic Hospital. London: *The Medical Times*, Limited. 1904. Pp. 87. Price 2*s.* 6*d.*—These lectures, we presume, represent the instruction given by Mr. Grimsdale to his pupils at St. George's Hospital. They supply information on errors of refraction sufficient for the average student and if thoroughly digested will to a certain extent enable him to understand the principles on which the refraction of the eye rests and the means by which deviations from normal conditions are recognised and corrected. It is taken for granted that the student has had practical lessons in the use of the ophthalmoscope but vision testing is fully described. Mr. Grimsdale considers that in almost every case below the age of 60 years, when accommodation is usually lost, it is advisable to use a mydriatic, atropine being employed for children and homatropine for adults. He very prudently observes that since the risk of glaucoma increases with age no patient who has been homatropinised should be allowed to leave the consulting room without the instillation of a drop of solution of eserine to neutralise the effect of the mydriatic. The principles on which retinoscopy rests are satisfactorily given and the mode of selection of glasses for the conditions of myopia, hypermetropia, and astigmatism is described in some detail, illustrative cases being added. It would be of advantage to the student if the notation of the prescription for glasses to be presented by the patient to the optician were more fully explained; such orders as those given on pp. 51 and 52 would not be readily understood without some attendance in the out-patient room. Mr. Grimsdale alludes to the performance of the operation of extraction of the lens in cases of high myopia. He does not, however, mention the limits between which it is legitimate to undertake it but simply remarks that eyes with high myopia are not healthy and that accidents are not infrequent. His personal experience has led him to regard the operation with some disfavour, 20 per cent. of the cases operated on subsequently suffering from detachment of the retina. Mr. Grimsdale will do well in the next edition of his little *brochure* to provide a better set of diagrams; those which he has inserted are rough and coarse and not always correctly lettered.

A Manual of Obstetrics. By A. F. A. KING, M.A., M.D. Ninth edition, revised and enlarged. With 275 illustrations. London: Kimpton. 1904. Pp. 622. Price 12*s.* 6*d.* net.—A text-book which has reached its ninth edition does not call for any extended notice on our part. In the present edition some errors have been corrected and various additions made. The author has been careful to preserve the character of the book as an elementary work intended only to present an outline of the rudiments and essentials of obstetric medicine to the student at the outset of his studies. It is not to be expected, therefore, that the work of revision will have been carried so far as to include all the recent advances in obstetric medicine. Were this so it would be easy to pick out many chapters which could not for a moment be considered up to date in the case of a more ambitious work. There can be no doubt that the book has adequately fulfilled the purpose for which it was written and we think that the present edition will continue to do so as well as its predecessors.

The Annual Charities Register and Digest, 1904. London: Longmans, Green, and Co. and the Charity Organisation Society. Pp. 750. Price 5*s.* net.—This admirable digest of "charities in, or available for, the metropolis" keeps up its high standard of information. The introduction by Mr. C. S. Loch contains everything that an almsgiver should know for the proper allocation of his alms. There is an index which is a model of accuracy and is full of cross references, while the body of the book gives details of all kinds of charities rightly so-called and in addition of a number of polemical "religious" societies which have no claim to the name. But the book is indispensable to anyone who wishes to help his poorer brethren in the best way.

The Oxford and Cambridge Year-Book, 1904. Part 1, Oxford. Edited by A. W. HOLLAND. London: Sonnenschein. Price 3*s.* 6*d.* net. Pp. 687.—This work may be called a university "Who's Who?" The editor's aim, as expressed in his preface, is to give "particulars of the degree—together with other distinctions—present occupation, and address of all now living who have graduated, or who are entitled to graduate, at either Oxford or Cambridge." So far as we can test the work the editor seems to have succeeded very well. The present volume will be found of great interest to all Oxford men and we look with pleasant anticipations to the forthcoming volume on Cambridge. On p. 346 the name "Kepple" is surely a misprint for "Keppel."

Analytical Records

THE LANCET LABORATORY.

SPARKLING SAUMUR. (1) DRY ROYAL, (2) BRUT ROYAL.

(ACKERMAN LAURANCE. LONDON AGENTS J. N. BISHOP AND SONS, 13, COOPER'S-ROW, CRUTCHED FRIARS, LONDON, E.C.)

THE sparkling wines produced in the Saumur district of France are really excellent and deserve to be known better, for they are equal in many respects to the sparkling wines of Champagne. Of late considerable attention has been turned to the *production* of sparkling white wines outside the Reims district with very satisfactory results. Dietetically there is no reason why good sound, dry, sparkling saumur should be inferior to champagne wine, while it is generally of a light and non-acid character. According to our analysis the following represents the composition of two excellent types of sparkling saumur as above described. 1, Dry Royal: extractives, 4·57 per cent.; mineral matter, 0·17 per cent.; alcohol, by weight 13·15 per cent., by volume 16·24 per cent., equal to proof spirit 28·46 per cent.; volatile acidity reckoned as acetic acid, 0·06 per cent.; fixed acidity reckoned as tartaric acid, 0·57 per cent.; sugar, 2·47 per cent.; and volatile ethers reckoned as ethyl acetate, 0·03 per cent. This is a medium dry wine with excellent bouquet and flavour. 2. Brut Royal: extractives, 2·87 per cent.; mineral matter, 0·12 per cent.; alcohol, by weight 12·77 per cent., by volume 15·77 per cent., equal to proof spirit 27·64 per cent.; volatile acidity reckoned as acetic acid, 0·054 per cent.; fixed acidity reckoned as tartaric acid, 0 53 per cent.; sugar, 1·31 per cent.; and volatile ethers reckoned as ethyl acetate, 0·023 per cent. This is an agreeably dry and sound wine which is practically free from volatile acidity. The bouquet and flavour are excellent. These wines are very good examples of sparkling saumur and there is no doubt that for invalid purposes they would serve as well as champagne. The restorative value of champagne wine is well known and there is no reason why sparkling saumur wines of this type should not be dietetically and medicinally as good. Where expense is a consideration sparkling saumur may be ordered with confidence for the same stimulating and restorative properties which qualify expensive champagnes.

"KUMA."

(COSMO CHEMICAL CO., LIMITED, 72, FARRINGDON-STREET, LONDON, E.C.)

We have been informed of the composition of this antiseptic fluid which is intended more particularly as a mouth wash although it may be used for other purposes in which a germicidal action is required. The formula is an excellent one containing well-known antiseptics, essential oils, and aromatics. It is free from harmful substances and is very pleasant to use. The vendors make no secret of the composition, so that medical men and dental surgeons may know exactly what they are employing. Our analysis has confirmed substantially the statement made in regard to the composition.

ALBUMENISED HUMANISED MILK.

(E. G. COOK, ASHFORD FARM, ASHFORD, MIDDLESEX.)

We have received two samples of milk from the above farm which have been modified to meet the special requirements of infants. Sample No. 1 was made with cow's milk, cream, lactose, colostrum, water, and a small quantity of potash and bicarbonate of soda. Sample No. 2 was made by subtracting from cow's milk a part of the casein and then adding cream, lactose, a small proportion of alkali, and the yelk and white of an egg. Both samples are so treated as to split up the fat globules and prevent their separation; they are then bottled under pressure of carbon dioxide and oxygen gas and afterwards heated to 150° F. for half an hour. According to our analysis this process succeeds in bringing the composition of cow's milk very closely to that of human milk. Thus the analytical results given by Sample No. 1 were as follows: fat, 2·65 per cent.; proteid, 1·98 per cent.; lactose, 5·42 per cent.; and mineral matter, 0·41 per cent. Sample No. 2 gave the following results: fat, 2·82 per cent.; proteid, 2·24 per cent.; lactose, 6·27 per cent.; and mineral matter, 0·65 per cent. The mineral matter is in slight excess owing to the addition of a little alkali and bicarbonate of soda. This milk is stated to give excellent results in infant feeding and medical opinion is quoted in favour of its employment. An important feature of the milk is that the antiscorbutic qualities of the fresh milk are retained unimpaired.

"TABLOID" OPHTHALMIC DIONIN.

(BURROUGHS, WELLCOME, AND CO., SNOW-HILL BUILDINGS, LONDON, E C.)

Dionin, or ethyl-morphine-hydrochloride, has been very favourably spoken of in ophthalmic practice. The drug possesses definite analgesic properties and is said to be free from the disabilities of morphine and its salts. So far no euphoric symptoms it is stated have been reported to follow the use of dionin. Moreover, with the single exception of codeine phosphate, dionin is the most soluble morphine derivative. It is used in iritis, keratitis, glaucoma, vitreous and corneal opacities, and in sympathetic ophthalmia. The tabloid contains 0·0005 gramme of dionin.

BORO-THYMOL.

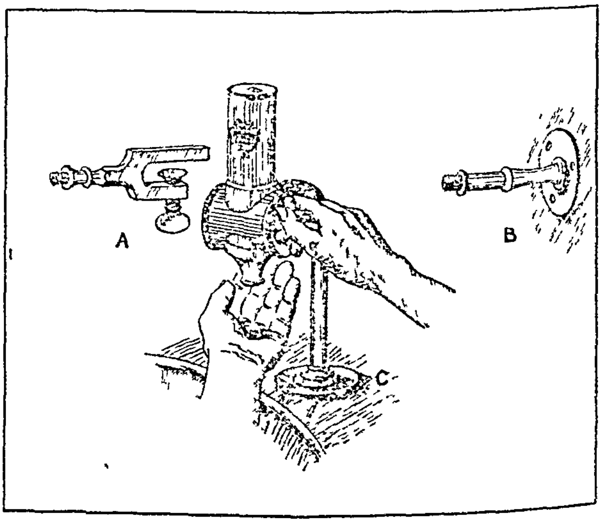
(THOS. STEPHENSON, 137, GEORGE STREET, EDINBURGH.)

The composition of this agreeable antiseptic fluid is simple, while the antiseptics employed, though powerfully germicidal, are neither injurious nor corrosive. We found alcohol present and a residue was obtained amounting to 2 37 per cent., consisting of boric and benzoic acids. In addition there were present the volatile substances thymol, menthol, eucalyptol, and oil of wintergreen. The preparation is useful for application to wounds, for douching the nasal cavities, or as a gargle for the throat. It may be taken also internally to check gastric and intestinal fermentation, while it affords a pleasant wash for the mouth and teeth.

New Inventions.

THE "ONDO" SOAP DISTRIBUTOR.

THE principal object of the apparatus shown in the accompanying illustration is to avoid the use of one piece of soap successively by a number of persons and to provide a means by which each of them may have a separate portion of soap sufficient for purposes of ablution. Its principal parts are a reservoir for soap in the form of a loose powder and an arrangement for the delivery of this powder in quantities as required. The reservoir is an upright nickel-plated cylinder having a total length of about six and a half inches and an internal diameter of an inch and a half. The distributor is contained in the short horizontal cylinder, and when the four-armed cross shown at one end of it is turned small quantities of the soap powder are delivered from the opening at the lower end into the palm of the hand. Three methods of mounting the distributor are provided—namely, by means of a support clamped to a shelf, as at A; or by a horizontal arm fastened to a wall as at B; or by a vertical standard bent horizontal at its upper part as at C. The price (nickel-plated) is 12*s.* 6*d.* Soap "refills" are supplied at 4*s.* per dozen, antiseptic and either perfumed or plain as desired. The weight of the apparatus full of soap is about two pounds. The makers are Messrs. John Bolding and Sons, Grosvenor Works, Davies-street, London, W.



BRISTOL CHILDREN'S HOSPITAL CONVALESCENT HOME.—The tenth annual meeting of the subscribers to the Children's Convalescent Home at Weston-super-Mare, which is in connexion with the Bristol Children's Hospital, was held on May 7th under the presidency of Mr. R. E. Dickinson, M.P. The medical report stated that 338 children had been admitted during 1903, the average stay in the home being three weeks. The financial statement was satisfactory.

THE LANCET.

LONDON: SATURDAY, MAY 28, 1904.

Physical Exercises for Children.

IT is as important for the well-being of a nation that its citizens should be strong physically as that they should have had mental training. A race of intellectual valetudinarians will surely fail in the present keen struggle for existence. During childhood the body and the mind are alike in a plastic state and can be moulded to a surprising extent by carefully directed training. It is therefore in childhood that the future citizens can be fitted for their future work, both mental and physical. Long ago the need for training of the mind was recognised and the many ancient endowments throughout the country bear witness to the long duration of the appreciation of mental training. It is, however, only within recent years that men have come to see that to obtain the best results physical training is also needed. The spontaneous physical exertion during playing is doubtlessly of inestimable value but with properly directed and coördinated exercises even better results are seen. With the recognition of the value of physical exercises the need for a suitable course of training arose. Many works on the subject have appeared and a "model course" was officially recognised for use in public elementary schools. It has been felt, however, by many of those who have studied the subject most deeply that the time has come for revising the scheme in the light of experience. A committee was therefore appointed to investigate the matter. It was under the chairmanship of Mr. J. STRUTHERS, C.B., and we are glad to see that it contained amongst its members two medical men—Dr. J. KERR and Dr. A. L. S. TUKE. It was essential that some members of the committee should possess medical knowledge, as the whole theory of physical training rests on a physiological basis. The report of this committee has recently been presented to Parliament and it deserves attention. The terms of reference to the committee were: "To examine the model course now in use, to judge how far it should be modified or supplemented, and to consider what principles should be followed in order to render a model course or courses adaptable for the different ages and sexes of the children in the public elementary schools."

With the course suggested in the Blue-book we are not especially concerned except that we may express our general approval. It is rather to the principles on which the course has been founded that we must direct our attention. It is often said to be unwise to give the reasons for an opinion, for the reasons may be more open to criticism than the opinion which depends on them. But we think the committee has done wisely in setting forth fully the principles which underlie the suggested model course. In the first place, the committee has endeavoured to exclude from the course all exercises which appear to be in the least likely to prove injurious to children of even weak physique. This was essential, as the course is intended for public elementary schools, and it must be remembered that the general average standard of physique in these schools is not high. The report further points out that there are children who from the condition of their health ought to be at times, or altogether, excluded from participation in these exercises. The suggestion is made that in future the teachers should receive instruction in the laws of health and in the outward signs of physical and mental weakness and that they should be taught to recognise probable deviations from normal health and normal physique. Teachers should be able to recognise the signs of defective nutrition and those defects of sight, hearing, and breathing which require medical attention and they should be familiar with the signs of fatigue, physical or mental. To attain this power of recognition of deviations from the normal a certain amount of practical training would be necessary for the teachers, for no amount of mere book-knowledge would suffice. Equipped with this capability of recognising the abnormal the teacher would be able to select the children who require further investigation which must be made by medical men and preferably by medical men who have specially studied the subject. We would suggest that it would be desirable that a medical man should now and then see a class during and immediately after a lesson in physical exercises, as he might thereby be enabled to detect abnormalities which had escaped the eye of the teacher. The report recognises that it is preferable that all physical exercises should be conducted in the open air but in this uncertain and very variable climate it is not practicable to make it a rule. The value of physical exercises depends in great part upon the regularity with which they are performed but the weather may make it necessary to suspend exercises in the playground for weeks together; therefore sometimes at least the exercises must be conducted within doors. In such cases, if possible, the windows should be open during the exercises so that as much fresh air as possible may be admitted into the room while the children are in active movement.

The report divides the effects produced by the exercises into "physical" and "educational." By the "physical" effect is meant the maintenance and improvement of the health and physique of the children. By the "educational" effect is meant the development in the children of the qualities of alertness, decision, concentration, and perfect control of mind and body. It is possible to distinguish between these two effects but they should be blended in every exercise, though in some one will preponderate and in some the other. The most important of the exercises producing a "physical" effect are those which have primarily a beneficial influence on respiration and circulation and as they thus improve nutrition they have been called "nutritive" exercises. These nutritive exercises include massive movements of the lower limbs, involving the whole bony and muscular structure of the body, and thus quickly and powerfully affect both respiration and circulation. Many exercises of this nature are to be found in the natural play movements, such as running, leaping, and skipping, and so far as possible these should be encouraged. Exercises which involve mainly the upper limbs and special breathing exercises tend to develop the and flavour. 2. Brut Royal: extractives, 2 87 per cent.; mineral matter, 0·12 per cent.; alcohol, by weight 12·77 per cent., by volume 15 77 per cent., equal to proof spirit 27·64 per cent.; volatile acidity reckoned as acetic acid, 0·054 per cent.; fixed acidity reckoned as tartaric acid, 0 53 per cent.; sugar, 1·31 per cent.; and volatile ethers reckoned as ethyl acetate, 0·023 per cent. Bristol Children's Hospital Convalescent Home.—The tenth annual meeting of the subscribers to the Children's Convalescent Home at Weston-super-Mare, which is in connexion with the Bristol Children's Hospital, was held on May 7th under the presidency of Mr. R. E. Dickinson, M.P. The medical report stated that 338 children had been admitted during 1903, the average stay in the home being three weeks. The financial statement was satisfactory.

last year was only 16·3 per 1000, being less by 1·1 per 1000 than the low rate of the preceding year. As in previous summaries, a table is given on pp. 4 and 5 in which the death-rates in the several towns are corrected for differences in the age constitution of their populations, and in the last column will be found the "comparative mortality figure" for each town, by means of which the towns have been arranged in a series indicating their relative position at a glance. The comparative mortality figure of England and Wales being taken at 1000 the table shows that the towns with the lowest mortality are Hornsey with a comparative figure of 581, King's Norton of 676, and Leyton of 722. At the other end of the scale come Manchester with a comparative figure of 1430, Middlesbrough of 1522, and Wigan with a figure of not less than 1538, as against 1000 for the country generally. Amongst the causes of death small-pox appears to have been distributed more widely than usual during the year. This disease caused 415 deaths in the great English towns and 90 in the smaller. Of these, 137 belonged to Liverpool, 25 to Manchester, 23 to Oldham, 22 to Leeds, 21 to Leicester, 19 to Gateshead, 14 to Cambridge, 13 to London, 12 each to Birmingham and Bradford, 10 to Burnley, nine to Newcastle-on-Tyne, and smaller numbers to 99 other towns. Measles caused a mortality of 0·36 per 1000 in the great towns, 0·45 in London, and 0·29 in the smaller towns. Scarlet fever was fatal to 0·14 per 1000 of the population in the great towns, 0·08 in London, and 0·12 in the smaller towns. Diphtheria was fatal to 0·20 per 1000 living in the great towns, 0·16 in London and also in the smaller towns. For whooping-cough the rates were 0·33, 0·35, and 0·28 per 1000, for fever 0·12, 0·08, and 0·11 per 1000, and for diarrhœa 0·71, 0·64, and 0·43 per 1000 respectively. Infantile mortality, measured by the proportion of deaths under one year to each 1000 births, was equal to 144 per 1000 in the great English towns, to 131 per 1000 in London, and to 135 per 1000 in the 103 smaller towns. Of the total deaths there occurred in hospitals, workhouses, or other public institutions 22·7 per cent. in the great English towns and 35·4 per cent. in London. Coroners' inquests were held in respect of 7·9 per cent. of the total deaths registered in the 76 great towns and in respect of 10·2 per cent. in London, the proportion ranging among the several groups of metropolitan registration districts from 8·5 per cent. in the southern group to 14·8 per cent. in the eastern. Of the total deaths registered the proportion of uncertified deaths was 1·1 per cent. in the 76 great towns and 0·3 per cent. in London.

A useful addition to the summaries of the last few years consists in the insertion of a table showing the number of cases of infectious disease notified in the chief towns of England and Wales. With regard to small-pox, for example, we note that although only 13 deaths occurred in London as many as 416 cases of this disease were notified during the year, the greater part of which were isolated in hospital. In addition to the reported attacks of small-pox in the metropolis there were notified in Birmingham 254 cases, in Leicester 368, in Liverpool 1661, in Manchester 419, in Leeds 442, and smaller numbers in most of the other towns in the list. Reference to this table further shows the number of notified cases of scarlet fever, diphtheria, "fever," erysipelas, and puerperal fever. The only defect in this table seems to be that no statement is made of the total cases of the several infectious diseases that have been notified to the sanitary authorities concerned. This defect we hope to see remedied in future years.

◆

Sociology.

THE opening meeting of the new Sociological Society, as to which we made some observations recently, appears to have been well attended and successful; but we doubt whether anything deserving the name of sociology can at present be said to exist, or whether the scattered knowledge bearing upon the questions comprised under the term has at present been sufficiently systematised to be of the slightest practical value as a help either to the attainment of good or to the avoidance of evil. Mr. GALTON wishes us to aim at the improvement of the human race by the aid of "Eugenics"—that is to say, by the careful selection of the parents of future generations. But he has not clearly shown either upon what principle they are to be selected or by whom the selection is to be performed. The rough and ready methods which have hitherto prevailed do not satisfy him, but where are we to turn for reform? The methods in question already differ much in different countries, and it may be that some of them are better than our own. In England the chief cause of attraction between the sexes is undoubtedly propinquity, in the sense that young men and young women of the same class are very much cast in the same mould, and the question whether REGGIE shall fall in love with ROSE or with DORA (if we may borrow our names from the charming poem in which Mr. AUSTIN DOBSON has described a not uncommon series of events) is largely dependent upon the chances which may throw one or the other across his path at a critical moment. In France, on the other hand, the predilections of parents are often of more importance than those of the young people themselves, and questions of *dot* predominate over any which arise from appearance, from character, or from disposition. Can it be said that any results dependent upon the difference are distinctly traceable in the two countries, or that the experience of either of them is sufficient to establish a rational theory? We think not.

We must not, of course, be supposed for a moment to deny the existence of underlying principles which may be potent in shaping the destinies of humanity, but we deny that these principles have yet been discovered or clearly enunciated, and we protest against the premature acceptance of hypotheses which have been subjected to no sufficient examination. Dr. ARCHDALL REID is reported to have said at the first meeting of the Sociological Society that "at the root of every moral and social question lay the problem of heredity," and that "until a knowledge of the laws of heredity was *more widely diffused* the public would grope in the dark in its endeavours to solve many pressing difficulties." We have italicised the most important words in the above sentence because they seem to us to imply a proposition from which we entirely dissent, the proposition that the laws of heredity are known somewhere or by some persons, and that the chief requirement of mankind is for this knowledge to be diffused. We apprehend, on the contrary, that the chief requirement is for such knowledge to be gained and we are certain that this is Dr. REID's own opinion. The problems of heredity were as embarrassing to philosophers 250 years ago as they are to-day, and are apparently not much nearer to a complete solution. MALEBRANCHE wrote that some of the qualities of his contemporaries were clearly derived from "our first parents," and WEISMANN and his followers have done little more than suggest almost mechanical explanations of the way in which inheritance from remote ancestors may modify the natures of the men and women of to-day. We would earnestly warn sociologists against being tempted into hasty generalisations from insufficient data, and also against a tendency which too often besets the followers of nascent departments of science, a tendency to exaggerate the value and importance of the results which preliminary inquiries have appeared to indicate.

Mr. H. G. WELLS, a fascinating and suggestive prophet, is inclined to look to the sterilisation of failures, and not to the selection of successes, for improvement in breeding; and there can be no doubt that civilised nations are heavily burdened by the offspring of criminals and imbeciles who for the public good should be placed under restraint. The slums of all our big cities contain hundreds of people whose privilege it is to claim descent from a prostitute and a thief, and who are certain in their turn to be the parents of offspring inheriting the parental tendencies and qualities. The *proletarius* of old Rome was a citizen whose condition was so mean that the only service he could render to the State was to beget children for its defence. We cherish vast numbers of undesirables whose children are at once a danger and a disgrace; and yet we are beginning to feel the effects of a diminishing birth-rate. We commend this problem to the Sociological Society for consideration. It is difficult to suggest means for the sterilisation or segregation of the undesirables without giving too much offence to sentimental philanthropy; and the nation as a whole is in need of men. The society may do good service to the country by making representations on these matters which shall be weighty enough to attract the attention of the public.

◆

The Stockport Hospital Scandal.

WE have received several copies of a local newspaper, the *Stockport Advertiser*, containing a voluminous account of what is called "The Stockport Hospital Scandal." We have also received sundry communications upon the matter in question which presents many features calling for comment in a medical newspaper. It appears that at one of the Stockport hospitals for infectious diseases, under the jurisdiction of the Stockport town council, a charge-nurse was asked to resign for certain acts which were construed as insubordination, the circumstances being peculiar. The first act of insubordination, according to a statement made by her superior officer, the matron of the Stockport borough hospitals, was the reporting to the medical superintendent of the borough hospitals, Dr. MEREDITH YOUNG, who is also medical officer of health of Stockport, inefficiency in the management of the hospital. The second act of insubordination alleged against the charge-nurse was that, when she was blamed for having reported errors of administration at the hospital, she telephoned asking the medical superintendent to come to the hospital and settle the points at issue. The medical superintendent arrived upon receiving the summons and matters appear for the time to have been settled, but relations between the charge-nurse and the matron remained strained. The matron is stated by the charge-nurse to have refused to take telephonic communications between the hospitals from the charge-nurse about the patients' requirements, and the charge-nurse made other allegations against the matron; the hospital subcommittee sat on the matter and it was deemed advisable that the charge-nurse should be asked to send in her resignation. The complaints made by the charge-nurse were: (1) that the hospital in her charge had been left without domestic service from 9 A.M. to 5 P.M. at a time when there were severe cases; (2) that ice ordered by the medical superintendent at 11 A.M. did not arrive till 9 P.M. on the day following, the order having been transmitted through the matron; (3) that the soiled linen of a case of diphtheria had been left on the bed in the observation ward of the hospital under the matron's jurisdiction for five weeks; and (4) that practical joking, dancing, and general merriment of a sort which the circumstances made indecent had prevailed in that hospital without the knowledge or consent of the medical superintendent in the infected wards and in the neighbourhood of sick patients.

The hospital subcommittee met six times about the matter. The charge-nurse was not allowed to appear in substantiation of her complaints against the matron or in opposition to her own dismissal. But after dismissal unheard the committee invited her to come to the hospital and make her accusation against the matron, a course which she properly declined to take unless assisted by a solicitor. The hospital committee refused to accede to her request, and at the conclusion of a prolonged meeting held on April 18th, at which the matron and her witnesses only were heard, the following resolution was passed:—

"That it is the opinion of this committee that the matron has done the best she could in the interests of the hospital and the patients, but that there seems to be a need for a revision of the rules for the future guidance of the matron, and that in view of certain matters of an irregular nature that have been admitted by the matron, she be reprimanded by the chairman."

An amendment, moved by Councillor H. G. SMEETH, a medical man, seconded by Councillor A. G. WILKINSON, was lost.

"That, in the opinion of this committee, the serious charges that have been made against the matron of this hospital have been admitted in so far that this committee feels that it cannot do less than call upon her for her resignation."

The charge-nurse, being advised by solicitors, summoned the corporation for her wages, for board and lodging during suspension, and for legal expenses, and was paid.

The whole matter became public upon the report of the sanitary committee in endorsement of the action of the hospital subcommittee coming up for approval at a meeting of the town council. It having been moved that the reports as read be passed, confirmed, and adopted, a long debate followed on an amendment proposed by Dr. H. G. SMEETH, who evidently considered that the charge-nurse had been dismissed in an arbitrary manner unheard and that the matron had been whitewashed in an unsatisfactory way. Dr. SMEETH lost his amendment, the voting being practically upon political lines, but there are circumstances why it is not likely that the matter will rest here. A medical man named Dr. HYDE MARRIOTT, a town councillor of Stockport but not a member of the hospital subcommittee, who was not present at any of the meetings in which the conduct of the matron and the charge-nurse had been discussed, and who had therefore no knowledge of the various points in the matter save what he might have derived from hearsay, rose to defend the matron from Dr. SMEETH's amendment, basing his action on chivalry. He is reported in the *Stockport Advertiser* to have said that "the voice of scandal had no effect on an honest man, who had his remedy with his fist, but that with a woman it was very different." He owned that he had not been to the hospital himself, but he said that he had heard from the best authority possible that the matron was an excellent matron and he then proceeded to make charges against the medical superintendent, Dr. YOUNG, whom he found guilty of all the failings which the matron had admitted, because the medical superintendent was in general charge of the hospitals. He is reported to have said that the cause of the present trouble was that the medical superintendent was too fond of listening to tittle tattle, that the matron had plenty of work to do and would not think of looking whether "dirty things" (referring to the linen of the diphtheria patient) had been taken out of the observation ward. "Why did not the medical officer do it?" he asked; "he was equally responsible with the matron. It was his duty to look after that." He criticised the medical superintendent's treatment of a case and wound up by making, whilst sheltering himself behind unnamed authority, the statement that Dr. YOUNG had received a gratuity from a nurse who had been discharged for drinking.

We have no hesitation in saying that Dr. MARRIOTT made a grave professional error in behaving as he did at the Stockport town council. While accusing Dr. YOUNG of listening to tittle-tattle he made a speech based entirely upon hearsay in which he was betrayed into mendacious allegations of a most serious character. It is true that, later he apologised for the accusation which he had brought against Dr. YOUNG of receiving a gratuity from a drunken woman but he appears not to have been given an opportunity of doing so until after the voting upon the amendment had taken place, and no amount of apologies will put the matter right. A gentleman is not supposed to escape the responsibility of making vile accusations by a few words of confession of error. But not only was Dr. MARRIOTT guilty of a gross breach of ordinary manners but he has defaulted from professional standards by trying to hold up a professional brother to public contempt. The presence of medical men upon municipal bodies can be extremely valuable to the community and to the medical profession because they can explain to their lay colleagues in the municipality medical points, the proper jurisdiction of medical officers, the duties of house surgeons and nurses, the recognised ethical methods of the medical profession, and so on—matters which sometimes are puzzling for the layman to understand. What, however, are we to think of a councillor who uses his position on the town council absolutely to misstate what are the official duties of the medical officer of health of a borough and to do so in a speech which already contained a malignant innuendo? Dr. MARRIOTT should know perfectly well that it is not the business of the medical superintendent to see that dirty sheets are washed. It is the medical superintendent's business to give general orders with regard to disinfection, particularly when he is dealing with a matron whose nursing experience has not brought the point within her ken, but it certainly is not his business to spy into linen-baskets and washing books to see whether the linen is washed.

The story is an unpleasant one in every way and we strongly recommend those inhabitants of Stockport who are interested in their municipal government to think over what has happened. A charge-nurse has been dismissed unheard, her legal claim for wages, made by summons, having been paid later. A matron who admits charges of incompetency, who admits having been rude to the medical officer of health, and who plays jokes in sick wards remains in charge of a borough hospital. A valuable public official is accused in public by a professional colleague of taking a gratuity from a drunken woman. The votes which are to register the view of the town council upon certain aspects of these serious matters are given upon political grounds.

Annotations.

"Ne quid nimis."

THE AMENDMENT OF THE LUNACY ACTS.

AS we announced last week a Bill to amend the Lunacy Acts was introduced on Wednesday, May 18th, in the House of Commons by the Attorney-General and was read for the first time. We see no particular reason why its provisions should not become law at once, but even if this does not occur the advantage, at any rate, is gained that the subject will receive further discussion, from which medical men and those interested in the welfare of the nation will learn what are the public views on certain necessary reforms. The Attorney-General's Bill provides for the temporary care of incipient lunatics, a class who at the present time in England are allowed to remain a source of danger to others and misery to themselves until some overt act of insanity allows of their being dealt with by law. Sir Robert Finlay's Bill provides that if a medical practitioner certifies that a person is suffering from mental disease, the disease not being confirmed, and if the certificate states that it is expedient, with a view to the patient's recovery, that he should be placed under care for a period therein stated, not exceeding six months, then during that period a responsible person, whose name and address must be stated in the certificate, can take charge of the patient, the provisions of the existing Lunacy Act notwithstanding. The certificate must not be signed by the person under whose care the patient is to be placed, and where a medical practitioner signs any such certificate he shall, within one clear day after signing it, send a copy of it to the Commissioners in Lunacy that the commissioners may visit the patient to whom the certificate refers. The person who receives a patient under such certificate must also within one clear day after receiving the patient give notice to the commissioners of his reception; and if the patient dies, or the residence of the person receiving him is changed within the period mentioned in the certificate, notice of the death or change of residence must be given to the commissioners. At the expiration of the time mentioned in the certificate the consignee of the patient must report upon the patient's condition to the Commissioners in Lunacy under a penalty of £50. Only one patient may be received at a time. It is clear that such an amendment of our present procedure as this will be of the greatest value, as opportunity of observation will be afforded in cases where treatment as a lunatic might be mischievous, but where to do nothing is to take still greater risks.

ANNUAL REPORT OF THE MEDICAL DEFENCE UNION.

THE annual report for 1903 issued by the council of the Medical Defence Union affords interesting reading to all concerned in the welfare of the medical profession. During the year 1903 over 1000 cases have been brought before the council for consideration, in addition to which a large number have been directly dealt with by the general secretary. No case conducted by the union has been compromised. From a table of the expenses incurred by the union in medical defence for the last 14 years it is calculated that the average cost of legal proceedings per head works out at 4*s.* 10*d.*, while the total legal and general expenditure, including all office and working expenses, averages 9*s.* 1*d.* per member. The steady increase of members of the union proves that it is firmly established in the estimation of the profession. Concerning the attitude taken by the Medical Defence Union in regard to the British Medical Association undertaking medical defence, the council states that in its course of action it has only adhered to the opinions expressed in 1898 when the British Medical Association at the annual meeting held at Edinburgh decided by a considerable majority that medical defence should not be undertaken by the association. This decision rested almost entirely on the fact that the work of defence was carried on so ably already that there was no necessity to alter the memorandum and articles of association in order to provide for such work. The annual report contains an account arranged in a tabulated form of a great many cases dealt with by the union. Within the space of eight years there have been placed in the hands of the legal adviser of the union 1194 cases which works out at an average of 150 cases for each year. Mr. Hempson, the solicitor to the union, is of opinion that each succeeding year brings with it more conclusive testimony to the respectful regard and wholesome fear in which the union is held by speculative litigants. That the greatest risk and danger to which a medical man is exposed is that of libel and slander is borne out by the fact that during eight years out of a total of 1194 cases 322, or nearly a fourth, referred to this particular offence. The union is now said to possess an accumulation of retractions and apologies signed by offending parties against whom proceedings have been taken on behalf of members sufficient in number to paper entirely one of the walls of the union offices. A woman whom one member had been attending entirely from humane and charitable motives as her position and means did not permit of her paying professional fees accused him to his partner of having had immoral relations with her and stated that unless a specific sum was paid to her the matter would be ventilated. She further stated that in order to remove the evidences of his guilt the member had performed upon her an illegal operation and that as a consequence her general health and condition had been seriously impaired. The woman was threatened with proceedings on the member's behalf unless she immediately retracted the gross charges, signed a statement admitting that there was absolutely no foundation for them, and apologising to the member for having made them, and this was done by her. In the following account of a case dealt with by the union the value of its prestige is well shown. A medical man was threatened by a local solicitor with an action for malpraxis on the ground that he had treated in the hospital a patient with gross want of care and skill. The solicitor demanded the name of the solicitors who would accept service of process in default of his paying a certain sum of money. The member at once communicated with the union who placed the matter in Mr. Hempson's hands. He wrote to the solicitor justifying the member's treatment of the case in every way and intimating that he would accept service of process on the member's behalf. In his reply the solicitor stated that "having regard to the fact that the case would be defended by the union he did not propose to proceed further." The report affords in other places much evidence of the benefits which the profession has received as a result of the union's work in connexion with the suppression of unqualified practice, and the union is now probably as well known to unqualified practitioners as it is to the impecunious litigant and the mere sending of a letter from the union offices has been sufficient in most cases to secure from unqualified practitioners a cessation of their practices. The annual report of the Medical Defence Union deserves greater attention than is usually bestowed on publications of this kind.

THE RESTRICTION OF LICENSING.

TEMPERANCE legislation moves faster in Canada than with us. According to the latest temperance figures the number of licences in Ontario has fallen from 6185 in 1875 to 2957 in 1903, or, on the basis of population, from one licence for 278 persons to one for 740 persons. The greatest reduction has been effected in the larger centres—a significant fact. The exercise of local option which has been experimentally tried in many districts has had the effect of notably restricting the sale of liquor. In 1897 the age of prohibition for minors was raised from 18 to 21 years. The latest hour allowed for the sale of intoxicants is 11 o'clock. Concurrently with these changes the limit of population with regard to licensing has been extended and no public-house is allowed to be opened in the immediate vicinity of a church or a school. These reforms attract attention as much because of their purposeful and methodical progression as because of their thoroughness. The people of Ontario, having made up their minds to be temperate, have, step by step and Act by Act, attained a very substantial measure of success and apparently without seriously deranging the machinery of commercial prosperity. In this country we are moving in the same direction but we move more slowly and not so certainly. Nevertheless there is a fairly general and increasing agreement of public opinion that the retail trade in intoxicants has hitherto enjoyed a too indulgent sanction and that it will bear considerable restriction. This feeling is reflected in the terms of the two latest Licensing Acts. The frankness with which the feeling has been interpreted by local justices is probably in some degree accountable for the more cautious and defensive character of the latter of these two Acts. The principle of compensation, which is so carefully provided for by this measure, cannot be objected to on the ground of equity. If it is observed without prejudice and with an honest desire to reduce the number of licensed houses within the limits of public necessity it will not prove a serious hindrance to the progress of temperance reform. The withdrawal of the prohibitory power from local justices is a step of more dubious utility. A local magistracy would certainly appear to be the best judges in questions as to the rights and requirements of a community, while the quarter sessions bench would constitute a court of appeal from their decisions if required. Everything must, however, depend upon the spirit in which the new Act is administered. It is much to be hoped that in granting licences under its provisions regard will be had to the importance of encouraging temperance among the people.

PUBLIC AMBULANCES.

THE use of ambulances in cases of accident and sudden illness has recently been a subject of discussion in the columns of the *Manchester Guardian* and an important addition to the correspondence was made on May 23rd by a letter signed by Mr. R. H. Wolstenholme of Salford, chairman of the Manchester Medical Guild, and by the two honorary secretaries of the guild. Briefly stated, the guild is in favour of a municipal ambulance and first-aid system available for the public in general without distinction of class and providing not only for patients who would probably be treated at one or other of the hospitals but also for those who would prefer to be removed directly to their homes. Moreover, the first aid rendered before removal by ambulance ought to be far more efficient than it is at present. Unnecessary haste in removal of patients is generally to be deprecated. The guild judiciously recommends that the first aid should be as efficient as the resources of medicine and surgery can possibly make it, that it should therefore be carried out by a properly qualified medical man, and that it should be available at any part of the district with the least possible delay. In order to avoid the expense and complications inseparable from the appointment of special emergency medical officers and the creation of dressing stations the guild suggests that the police should be empowered and directed to obtain the attendance of the nearest available medical practitioner who already has a surgery fitted up for dealing with emergencies.

ENDOGENOUS PNEUMOCOCCIC INFECTION OF THE EYE.

MODERN researches have shown that lesions in other parts than the lungs are frequently produced by pneumococci. In the eye conjunctivitis and suppurative keratitis may result from infection of external origin. But ocular infection of internal origin, the pneumococci being conveyed to the eye by the circulation, has received little attention. At the meeting of the Société Médicale des Hôpitaux de Paris on April 29th M. P. Le Gendre and M. V. Morax related the following case. A woman, aged 47 years, was admitted to hospital on Jan. 17th in a delirious condition. At the beginning of the month she took to bed with a feverish illness which her medical attendant attributed to "pulmonary congestion," and on the day before admission she became delirious. At the apex of the left lung there were subcrepitant râles and an expiratory "souffle." She did not appear to see clearly but there were no signs of ocular inflammation. The delirium continued, the temperature was about 104° F., and auscultation gave rise to a suspicion of infectious endocarditis. On the 19th there were diffuse cloudiness of the right cornea and pus in the anterior chamber. The conjunctiva and episcleral tissue were moderately injected. In the left eye the symptoms were less severe; there were slight iritis and fibrinous exudation in the field of the pupil. On the following days the condition of the left eye did not alter much but the pus in the right anterior chamber increased considerably. On the 22nd the right eye was enucleated. Death occurred on the 25th. The necropsy showed in the whole extent of the left lung extremely thick pleural adhesions. Apart from slight congestion and œdema no other macroscopic pulmonary lesion was found. There were vegetative endocarditis of the mitral valve and infarcts in the kidneys and the spleen. Examination of the right eye after enucleation showed purulent exudation in the retina, the ciliary body, and the anterior chamber. Microscopic examination and cultures revealed the pneumococcus in pure culture in the exudation. In the aqueous humour the pneumococci were as numerous as in a culture. The vegetations on the mitral valve were infiltrated with pneumococci. The heart's blood yielded the pneumococcus in pure culture. Evidently pulmonary infection preceded the pneumococcic endocarditis and pneumococcic septicæmia to which the patient succumbed. The clinical characteristics of the iritis enabled the pneumococcic nature of the infection to be diagnosed before a bacteriological examination was made. In another case of pneumococcic iritis of uterine origin with cerebral abscess observed by one of the writers the iritis ended in the production of a similar fibrinous exudation in the pupil. In the pus of the cerebral abscess the pneumococcus was found in pure culture. Some writers have published cases of suppurative choroiditis in pneumonia. In 1853 Arlt described the case of a child suffering from lobular pneumonia who had metastatic meningeal abscesses and suppurative choroiditis. In 1874 Pilchaud observed suppurative choroiditis with spontaneous perforation of the sclerotic in a woman who died from pneumonia with empyema. Natanson and Eversbusch have reported cases of pneumonia during influenza with irido-choroiditis, unilateral or bilateral. When the part played by the pneumococcus in pneumonia was discovered it became possible to establish more precisely the connexion between the ocular affection and the pneumonia. In 1892 Herrnheiser first demonstrated the presence of the pneumococcus in the ocular pus. The patient was a man, aged 67 years, who was admitted to hospital on March 25th for pulmonary trouble. On April 2nd there was suppurative infiltration of both corneæ with hypopyon. On the 10th there was left panophthalmitis with perforation of the cornea. In the right eye there were slight infiltration of the cornea, iritis, hypopyon, and yellowish exudation on the posterior surface of the crystalline lens. Death took place four days later. The necropsy showed fibrinous pneumonia of the left lung, suppurative meningitis, and acute aortic endocarditis. Pneumococci were found in all the ocular and other lesions.

THE UNIVERSITY OF WALES AND MEDICAL DEGREES.

A WELL-INFORMED article in the *Cardiff News* of May 23rd sets out in much detail a variety of arguments in support of the view that the University of Wales should be authorised to confer degrees in medicine. Of course the chief centre of interest in such circumstances would be the Cardiff Medical School which would naturally bear to the University of Wales the same relation as the Newcastle-on-Tyne Medical School at present has to the University of Durham. The Cardiff school may be said to date from 1893, when chairs in anatomy and physiology and a lectureship in materia medica and pharmacy were established, thereby making it possible for students of medicine to learn the subjects included in the first three years of medical study as required by all universities and colleges in Great Britain. Attendance on this portion of the curriculum at Cardiff is recognised and accepted by all universities and colleges. During last year there were in the Cardiff school 55 students of medicine and 20 special students in the public health department, making a total of 75. In 1903 there were 15 medical students registered at the school, the corresponding numbers being 18 for University College, London, and also for the University of Birmingham. As mentioned in our issue of May 21st, p. 1465, the subject of a supplemental charter conferring various additional powers is already being considered by the University of Wales and the chances of the University obtaining what it seeks seem good.

MODERN PERAMBULATORS.

A CORRESPONDENT who has returned to this country after an absence of 20 years is much exercised to find that a new fad has arisen "which may have a most serious effect on the rising generation. I refer to the baby carriages now in general use in which the unhappy child is propelled through the world backwards." We do not think that our correspondent need distress himself. The modern perambulator is far superior to the old-fashioned arrangement in which the unhappy child was placed on a narrow seat and fastened in with a strap. A weakly child in such circumstances when he fell asleep always fell forwards and sideways and was mainly supported by the strap which pressed on the abdomen while the child's head lolled over the side. The modern perambulator in which the child can lie is far better and it is of no great moment whether the child faces in the direction in which he is travelling or no; in fact, if he faces towards his nurse he can talk to her when he pleases, which, given an intelligent nurse, is a very good thing. There is, however, a form of perambulator, or push-buggy, to give it its name in the country of its origin, which is most pernicious. It is a little mail-cart which runs near the ground and can be folded up at will. The child in one of these is far too near the ground, the seat is too small, and there is next to no support for the feet. It is more than probable that the indiscriminate use of such conveyances may seriously injure a child's nervous system but the reclining form of perambulator is harmless even though the child does face the opposite way to which it is going.

THE SUNSHINE OF ENGLAND AND SWITZERLAND COMPARED.

Dr. J. W. Cook, the medical officer of health of the Clacton urban district council, sends us a most interesting table in reference to our remarks upon the relative amounts of sunshine in England and Switzerland which appeared in THE LANCET of May 14th. It will be seen by this table that Clacton-on-Sea, even in the dismal years of 1902 and 1903, had a decided advantage over nearly every other place mentioned in the matter of sunshine.

Comparative Sunshine recorded in the Month of April at the Undermentioned Places in England as per the Meteorological Office Weather Report for the Three Years 1902, 1903, and 1904.

—	1902. Hours.	1903. Hours.	1904. Hours.
Clacton-on-Sea	213 6	180·1	208·7
Newton Reigny (Penrith) ...	181 6	109 4	—
Bath	160 8	160 0	143 7
Lowestoft	125·1	102·1	112·1
Hastings	179 2	160·9	172 5
Eastbourne	176 2	140 9	145 5
Brighton	161 9	139 0	139 6
Worthing	185 6	172·3	168 6
Llandudno	229 5	172 5	161·1
Rhyl	197 0	164 5	138 6
Southport	107·7	164 9	166 8

Dr. Cook says: "Doubtless when Englishmen know that such a large amount of sunshine can be had so near home, rather than going so far for it they will be inclined to keep their money in England instead of spending it in Switzerland." We rather doubt this, for to get the most advantage out of a holiday there is nothing like going abroad. A holiday depends not so much upon sunshine as upon a complete change of scene, change of surroundings, of food, and even of language. Moreover, a holiday spent abroad as a rule costs much less than in this country. A month spent in Brittany or Normandy can easily be done for 10 francs per diem and the Briton who sighs for the food of his native land will now find that French coffee is quite as bad as English, only about one-third of the price. But it is still comforting to know that our much abused climate can produce as much sunshine as that of countries lying further south.

THE DISTRIBUTION OF PLAGUE.

THE medical officer of health of the Cape Colony states that for the week ending April 30th only 1 case of plague was reported throughout the colony—namely, a Chinese male at Port Elizabeth. Plague-infected rodents were also found in the town. In the Cape Town and Harbour Board area 629 rodents were examined but none was affected with plague. As regards the Transvaal, Lord Milner, telegraphing on May 21st, states that the plague return for the week ending May 21st was as follows: total number of fresh cases reported since May 14, 7—namely, whites, 2; coloured persons, 5. Of the cases reported 3 have been found to be not plague—making the present total of suspected and proved cases 140, of which 24 occurred in whites and 116 in coloured persons. The number of deaths since May 14th is 2, both whites.

MEDICAL SCIENCE PAPERS AT THE BONN MEETING OF THE GERMAN BUNSEN GESELLSCHAFT.

THE German Society for the Study of Physical Chemistry, known as the Deutsche Bunsen Gesellschaft, has been holding its eleventh annual gathering in Bonn and on May 14th a whole session of its time was devoted to the reading and discussion of papers of medical interest. Dr. Schroeder of Bonn dealt with the importance of cryoscopy (or freezing-point determination) in its relation to health and stated that by such observations upon the blood and the urine valuable light could be thrown upon the activity of the heart and the state of the circulation. Professor Dreser of Elberfeld followed with a paper upon the same subject, while Professor Arrhenius of Stockholm dealt with the Chemical Mass Action of Toxins and Antitoxins. He has carried out a long series of laboratory investigations on this subject and has arrived at conclusions which are opposed to the generally accepted theories of the action of these bodies upon each other. Professor Arrhenius is convinced that toxins and antitoxins obey the ordinary laws of chemical action and that they react with one another in the animal organism as weak acids react with weak bases in chemical mixtures. Dr. Ehrlich of Frankfort led the opposition to the views of Professor Arrhenius and stated that his own experience of the action of poisons gained in the Institute of Experimental Therapy in Frankfort, of which he is the head, had convinced him that the ordinary laws of chemical action would not explain the interaction of toxins and antitoxins. In the case of diphtheria his view of the action of the antitoxin was that it reacted with the toxin produced by the bacteria characteristic of the illness, but that such reaction was far more complex and difficult to follow than was foreshadowed by the theory of Professor Arrhenius. A number of authorities and writers on this subject joined in the discussion and striking differences of opinion were manifested. The fourth paper of medical interest was by Professor Nernst of Göttingen and related to the action of the electric current upon the nervous system. Experiments with high-frequency alternating currents upon frogs had been conducted by him and the results had proved that the usually accepted views upon the action of these currents were incorrect. Such currents he considers penetrate the body and do not simply spread out over its surface, and the laws which govern the passage of electric currents through electrolytes and conductors are found to apply in this case also. The nerves, in fact, behave in such cases, in his opinion, as half permeable membranes.

THE SUPPLY OF ICE FOR DOMESTIC USE.

THE supply of pure ice in this country for domestic purposes is not as abundant or available as it should be, and it is absurd that practically the only shop where it may be obtained is that kept by the fishmonger who keeps it not for purposes of consumption but for cooling fish. The fishmonger's shop does not always represent an environment that is, sanitarily speaking, satisfactory, yet when ice is wanted in sickness or in health the only tradesman that can be found to supply it is the fishmonger, and his supply is usually limited. It seems ridiculous that in the English summer the demand for ice should not be sufficient to warrant the establishment of a special agency for its supply. We feel sure that if such a scheme could be organised it would be widely appreciated and would succeed as soon as the public realised how much better and healthier it is to have their food and beverages kept cool during the days of a hot and seasonable summer. As it is they have to be content with semi-liquid butter and mawkish lukewarm beverages which should be cold, especially those which are aerated. A cheap and abundant supply of pure ice for domestic purposes would give the housekeeper a chance of keeping a cool store-room in which meat, poultry, eggs, and other perishable articles of food could be preserved. Not only would waste of food be so prevented but the ravages of the putrefying agencies of hot weather would be checked and the food saved from becoming unwholesome if not positively dangerous. In fact, we imagine that nobody will deny the very great advantages derived from keeping certain foods cold in the summer and preserving them in a state fit for consumption and attractive to the eye and palate, and yet practically no steps are taken to supply such an important and very evident need. This looks to us like lack of enterprise.

FIFTEENTH INTERNATIONAL CONGRESS OF MEDICINE.

THE Fifteenth International Congress of Medicine will be held at Lisbon in 1906 under the presidency of their Majesties the King and Queen of Portugal from April 19th to 26th inclusive. Membership of the Congress is confined to medical men and to other men of science introduced by the executive Portuguese committee or by the foreign committees. Subscription to the Congress is £1 or 25 francs or 20 marks for foreign members. The work of the Congress will be divided into 17 sections and the executive committee of the Congress is anxious to print all the official papers before the meeting, so they must be given in to the general secretary before Sept. 30th, 1905. Other papers sent in by authors wishing to read them at the Congress, if it is desired that they should be printed before the opening of the Congress, must be sent in before Dec. 31st, 1905. The official language of the Congress is French, but besides this tongue English and German may be used. Portuguese has been purposely excluded by the committee with the intention of diminishing the number of languages spoken and it seems to us that this somewhat self-sacrificing regulation is deserving of great praise. The president of the organising committee is Dr. M. da Costa Alemão and the general secretary is Dr. Miguel Bombarda, to whom all subscriptions must be sent at the Hospital de Rilhafolles, Lisbon. Any questions which deal with the scientific work of the sections must be addressed to the president of the committee of the particular section but anything that concerns the organisation of the general work of the committee must be addressed to the general secretary. The secretary for Great Britain is Dr. F. W. Pavy, 35, Grosvenor-street, London, W.

TWISTED PEDICLE OF AN OVARIAN TUMOUR THRICE REDUCED WITHOUT OPERATION.

IN the *Boston Medical and Surgical Journal* of April 7th Dr. C. A. Porter has published a case in which the twisted pedicle of an ovarian tumour was thrice reduced without operation. A woman, aged 35 years, had a normal confinement in May, 1900. On Dec. 22nd, 1903, she ate some unsound meat. She became sick in the night and vomited violently all the following day. After a severe attack of vomiting she was seized with sharp pain in the right iliac region. She saw and felt a lump there of the size of a small orange which disappeared after manipulation. The pain then ceased. On Jan. 5th, 1904, after carrying her child upstairs she had a similar attack of pain which lasted an hour. There was occasional vomiting. Menstruation had begun on the previous day more profusely than usual. On the morning of Jan. 11th she had a third attack. Menstruation still continued, although it usually lasted only three days. She vomited every 15 minutes. At 4 P.M. after an attempt at palpation the pain suddenly ceased. She was seen an hour later by her medical attendant who found a moveable globular tumour in the hypogastrium. On the inner side of the pelvic brim on the right side there was slight tenderness. Ovarian cyst the pedicle of which had become twisted, causing the three attacks of pain, was diagnosed. The point of tenderness appeared to indicate the position of thrombosed vessels due to the twisting of the pedicle. Immediate operation was advised on the grounds that the pedicle might become further twisted at any time with the production of gangrene. On opening the abdomen a purplish ovarian cyst in a moderate amount of fluid was found. It was rotated one-and-three-quarter times on its axis. The ovarian veins and the veins of the broad ligament were thrombosed at the site of the twist. A similar tumour was found on the left side. Double ovariotomy was performed but in view of the patient's age a little ovarian tissue was left.

JUVENILE TABES DORSALIS.

JUVENILE tabes has often been confounded by writers with Friedreich's ataxia, but if it is remembered that motor incoördination of the legs is ordinarily the first and the most striking manifestation of Friedreich's disease, whereas it is extremely rare in true tabes dorsalis, that the so-called pre-ataxic stage which is frequently, if not constantly, present in tabes dorsalis is never present in Friedreich's disease, and, finally, that the one disease (Friedreich's disease) has often a "family" character, while tabes dorsalis is by no means a family affection these, together with the differential symptoms recorded below, will serve to distinguish the two affections. In the *New York Medical Journal* of May 7th Dr. Alfred Gordon, instructor in neurology in the Jefferson Medical College, Philadelphia, deals with juvenile tabes dorsalis and calls attention to the following interesting points in the case recorded below which illustrates a new and as yet undescribed complication—viz., an attack of tabes dorsalis following after (but not due to) infantile paralysis. The case really shows that juvenile tabes is due to inherited or acquired syphilis, as juvenile general paralysis has long been known to be. In the great majority of cases acquired syphilis is the cause of tabes dorsalis in adults but in cases of juvenile tabes Dr. Gordon states that he could trace the causation to inherited syphilis, acquired syphilis being in this case excluded by careful inquiry. The case was that of a boy, aged 17 years, who at the age of 18 months had suffered from an attack of fever with convulsions and vomiting. After three days a total paralysis of the right arm was noted by the parents. The affected limb never recovered its power and could never be used again. The patient recovered from his illness and enjoyed good health after this until his fourteenth year, when he began to suffer from weakness and various paræsthesiæ of the left leg and numbness of the thigh and sole of the foot, so that he felt when he walked as though his feet "trod on soft cotton and not on the solid ground." Pains of a dull aching as well as lancinating pains were felt in the limb. A year later slight pains of a similar character developed in the right leg also. Hyperæsthesia of the bladder and some difficulty in expelling urine were noted. The remaining symptoms included feelings of "pressure and tightness" in the lumbar region and some weakness of vision. The right arm began to waste and wither away, the whole limb (except the hand) being much reduced in size. The skin was dry, flabby, and dulled to sensation and the reflexes were almost lost in this arm, while the muscles failed to respond to faradic or galvanic stimulation. In addition to these he showed various tabetic symptoms, such as "girdle" sensations and disturbances of the deep reflexes and of the sphincters, showing that the monoplegia of infancy was succeeded by the recent poliomyelitis. There were also loss of the knee-jerks, some inequality in the size and reaction of the pupils, and a slight ataxia of gait. These symptoms were undoubtedly due to tabes dorsalis and inquiry showed that when the mother of the child was pregnant with him she was infected with syphilis by the father. Dr. Gordon refers to the few rare cases of juvenile tabes recorded by Eulenberg, Morel, and a few others, showing that the influence of syphilitic infection in utero was a possible, as in this case it was a positive, etiological factor.

INDUSTRIAL EFFLUVIUM NUISANCES: YEASTS IN TANNING MATERIALS.

IN an annotation in THE LANCET of Nov. 1st, 1902, p. 1212, reference was made to an alleged nuisance arising from a tannery owing to the use of brewers' barm or yeast in the tanning process. It was stated that the presence of yeast in the waste liquors of a tannery strongly accentuates the offensive character of the effluent. The smell was described by residents and others as a "putrid offensive stench like that of highly decomposed animal matter." It would appear, however, that yeasts are present in all, or nearly all, of the vegetable materials used in the tanning industry, from which they can be isolated. Such, at any rate, is the conclusion arrived at by Dr. J. R. Carver who has just published the results of an investigation upon the subject undertaken in the Public Health Laboratory of the University of Manchester under the direction of Professor S. Delépine. During the course of an investigation upon the possible relations between the use of brewers' yeast in a tannery and the production of noxious gases Professor Delépine ascertained that various yeasts were present in all materials used in two tanneries as well as in all the liquors and effluents and that the fermentations to which they gave rise were not accompanied by the generation of noxious gases. Dr. Carver set out to ascertain firstly whether the various forms of yeast cells belonged to separate kinds or races of yeasts having distinct cultural characters or properties; secondly, the characters of the yeasts which could be isolated from the various tanning materials; and thirdly, if possible, whether yeasts played any useful part in the tanning process. It was found that yeasts are present in all of the materials, from which they can be isolated; they are present also in all the waste products but their isolation is difficult owing to the presence of a large number of bacteria. The yeasts in pure cultures do not produce any bad smelling gases and do not appear to contribute to the smell of the tan liquors. Finally, whatever share yeasts may have in the souring of ordinary tan liquors there was no clear indication of such action in any of the pure cultures studied and, moreover, in old tan liquors and waste products the yeasts did not seem to have increased in number equally with bacteria. On the basis of morphological and cultural characters Dr. Carver found it possible to recognise seven or eight varieties of yeasts but he is not able to state that these forms correspond to as many species, for after being grown for several generations in pure cultures some of the forms which at first appeared to be distinct gradually approached a common type.

THE SANDGATE SCANDAL.

ON various occasions attention has been directed in our columns[1] to the objectionable state of matters created by the homes for tuberculous patients which the late Mr. John James Jones established in Sandgate. From its situation on the coast of the English Channel Sandgate possesses many of the natural features suitable to a health resort and among the general residential population amounting to 1955 persons there were only 14 deaths during 1903. This mortality was, however, almost quadrupled by the deaths which occurred in various institutions or convalescent homes. Among visitors who had gone to Sandgate as patients in these establishments there were 50 deaths, 43 of which occurred among 881 tuberculous patients accommodated in the homes carried on by Mr. Jones. This influx of patients, among whom there was a death-rate of almost 5 per cent., could not fail to excite some uneasiness among the permanent residents in Sandgate, a feeling which found expression in an appeal made to the Local Government Board by Sir Edward Sassoon, Member of Parliament for the district. The reply received from the Board was unsatisfactory. It was to the effect that the Board had no power to move in the matter and that as Mr. Jones had recently died the time was inopportune for dealing with the question. Sir Edward Sassoon then brought the matter before the House of Commons on May 19th in an admirable speech, drawing the attention of the House to the increasing difficulties experienced by local authorities, and especially by small local authorities, in their efforts to restrict the establishment in populous districts of "consumptive homes" which did not enforce the precautions considered by the medical profession to be essential for the protection of the general public. The President of the Local Government Board, however, replied to the effect that no sufficient cause had been shown for the Board to take action. He said that a district could not be protected against infection by regulations, and that a consumptive patient in a home was less dangerous to the public than one who was not in a home, because in the latter case there was no restraint on his movements up to a late stage of his illness. With all due respect for these statements by the President of the Local Government Board we feel that to plant a colony of tuberculous patients in the midst of a small town is anything but an advantage for either the patients or the permanent residents. The Sandgate "Sanatoria" are not sanatoriums in anything but name. Leaving this point, however, aside a variety of reasons make it desirable that sanatoriums for the treatment of tuberculosis should not be in immediate proximity to centres of population. There are so many different phases to the question that it will be necessary to discuss it at greater length, particularly as a public health congress is about to meet at Folkestone, within two miles of these homes.

---

[1] THE LANCET, August 22nd, 1903, p. 565; Feb. 20th, 1904, p. 527.

ON the retirement of His Majesty the King from the office of President of St. Bartholomew's Hospital the governors decided to commemorate that illustrious presidency, which had extended over a period of 34 years, by procuring, by subscription amongst themselves, a portrait of His Majesty. That portrait, with His Majesty's permission, has been painted by Mr. Luke Fildes, R.A., and is a replica of the well-known picture exhibited in the Royal Academy in 1901. It has been placed in the great hall of the hospital.

Mr. A. Forbes Sieveking, son of the late Sir Edward Sieveking, is requesting the loan of any of his father's letters to assist him in writing an extended biography of this distinguished physician. The letters, or copies of them, as well as any memoranda of a personal kind illustrating Sir Edward Sieveking's character, should be sent to Mr. Sieveking at 12, Seymour-street, Portman-square, London, W.

THE annual dinner of the West London Hospital will be held at the Trocadéro Restaurant on Saturday, June 25th, when Dr. J. Barry Ball will occupy the chair. All those connected either with the Post-Graduate College or by past and present service with the hospital will be welcome. Communications should be made to Mr. L. A. Bidwell.

A MEETING of the Royal Medical and Chirurgical Society will be held on Tuesday, May 31st, at 8.30 P.M., at 20, Hanover-square, London, W., when Dr. W. P. Herringham and Dr. W. A. Wills will read a paper on the Elasticity of the Aorta, being a contribution to the Study of Arterial Sclerosis, which will be followed by a discussion.

Sir Dyce Duckworth delivered an address before the British Balneological and Climatological Society at 20, Hanover-square, London, W., on May 18th on the subject of British Winter Resorts. The address was followed by the annual dinner of the society and a smoking concert at the Criterion Restaurant.

Sir William H. Broadbent, Bart., Dr. Nathan Raw, and Dr. A. P. Hillier have been appointed to represent the British National Association for the Prevention of Consumption and other Forms of Tuberculosis at the International Conference on Tuberculosis now being held in Copenhagen.

THE forty-fourth annual dinner of King's College, London, will be held at the Hotel Cecil, on Monday, June 20th, when the Marquess of Salisbury will occupy the chair. Communications should be made to Mr. John Chapman, honorary secretary of the committee, at King's College, London.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—The authorities of this College have recently adopted regulations for academical costume. The general body of the Fellows are authorised to wear a black stuff Master of Arts gown, faced with a St. Patrick's blue Irish poplin border five inches in width, narrowing round the collar behind and extending to each end of the gown in front. Inside of the blue poplin there shall be a crimson Irish poplin lining five inches in width and of similar extent as the blue. The cap is black velvet with St. Patrick's blue and crimson tassel. The Licentiates' costume is similar but the poplin facings and linings are only two inches in width and the cap is black cloth with a black tassel. The gowns and caps may be worn at all public functions, College ceremonials, State and civic public meetings, and on all occasions when academical costume is worn by the Fellows of the Royal Colleges of Surgeons of England and Edinburgh.

EPIDEMIC OF PLAGUE IN JOHANNESBURG.

BY WALTER C. C. PAKES, M.R.C.S. ENG., L.R.C.P. LOND.,
MEDICAL OFFICER OF HEALTH, RAND PLAGUE COMMITTEE.

Previous Precautionary Measures.

PLAGUE having existed for many months on the south and east coasts of South Africa it was obvious to those who had charge of the public health in the Transvaal that sooner or later it was highly probable that the Transvaal would be visited by the disease. In order if possible to prepare for such an epidemic the medical officer of health of the Transvaal, the medical officer of health of Johannesburg, and the Government bacteriologist had all made arrangements for (1) preventing if possible the influx of plague into the Transvaal and (2) dealing with it should it arise.

These arrangements consisted of: 1 (as regards the *medical officer of health of the Transvaal*). The appointment of a special plague officer at Volksrust (the first town on the Natal line in the Transvaal), the establishment of an observation camp at Vereeniging, a general supervision of Asiatics, natives, and so on. 2 (as regards the medical officer of health of Johannesburg). It was felt that as Johannesburg was the point to which the vast majority of the traffic tended the first signs of plague would arise in that city whether in the human subject or in the rat. As early as February, 1903, the medical officer of health of Johannesburg sent out circulars to the local medical profession containing extracts from the Plague Memorandum, dated September, 1900, by Mr. R. H. Power. These circulars described the symptomatology of the disease and gave full directions for o[illegible] acterioscopic examination n[illegible] cases. He recommended and [illegible], in connexion with the Government, organised a plague camp within the confines of the Government lazaretto at Rietfontein in order that immediately upon the outbreak of plague all such cases as well as suspicious cases could be transferred at once. 3 (as regards the Government bacteriologist). The Government laboratories were specially developed in order to be able to undertake the bacteriological diagnosis of this disease even on a large scale. In January, 1903, the general manager of the Central South African railways was requested (1) to issue instructions to all his employés upon the lines of communication from the Cape, Natal, and the Portuguese borders to be on the look-out for any dead rats, and (2) to request the responsible officials where such were found to send them to the Government laboratories for diagnosis. The Johannesburg municipality appointed a professional rat-catcher and all dead rats found by him were sent to the laboratories for bacteriological examination and there examined.

The first intimation of the existence of plague in this colony was obtained by the Government laboratories in April, 1903, when a dead rat was sent to the laboratories from Johannesburg. This rat was shown to have died from plague. Between the previously mentioned date and the outbreak of plague in Johannesburg 13 rats were found to have died from plague. These rats came from different neighbourhoods in Johannesburg and the most careful inquiry failed to reveal the slightest connexion between any two spots from which dead rats had been obtained. The inevitable conclusion was that these rats had been imported singly from the coast in grain or forage. Each place from which a plague-stricken rat had been taken was visited by the rat-catchers and disinfectors and cleaned up. It is a noteworthy fact that it only once occurred that a second rat was obtained from the same place. The authorities did not confine their attention to rats; cats and dogs, and by chance ducks, fowls, and small birds, came under bacteriological observation, with the result that, although the rest proved negative, one cat was certainly found to have died from plague and this fact was also notified to the Government.

The Government laboratories had received from the Chamber of Mines a grant of money to be expended in [illegible] s of pneumonia occurring [illegible] rence to the deaths among [illegible] xamination of the rats and [illegible], in the human subject were [illegible] being carried on side by side in the same laboratory and by the same observers. It is practically impossible, therefore, as the Government laboratories were endeavouring to find the various causes of pneumonia in this country, that they should have failed to identify in the sputa which they were examining an organism which they were finding in the rats. It can therefore be asserted with confidence that no material from a case of plague in the human subject had been sent to the Government laboratories before March 19th, 1904. During the course of 1903 there was a scare of plague. This has been reported by the medical officer of health of Johannesburg in his annual report and this report has been sent to England. The Government laboratories certified these cases as cases of either streptococcal septicæmia or pneumococcal septicæmia. It may be suggested that the evidence of the bacteriologist was not sufficient and that the failure to isolate the plague bacillus from these cases was not conclusive evidence; but a careful consideration of the whole of the circumstances surrounding those cases (with two exceptions) showed that the bacteriological diagnosis coincided with the clinical and post-mortem appearances. The two cases in question were cases of natives who had suffered, according to the clinical and post-mortem reports, from adenitis. From these two cases an extremely pathogenic pneumococcus was isolated and the bacteriologist certified the cause of death as pneumococcal septicæmia. It may here be remarked that in this colony the pneumococcus produces conditions which are rarely met with elsewhere and many clinicians have found that in epidemics of pneumonia long prior to the introduction of plague into this country natives suffering from the usual pneumococcal disease did suffer from adenitis. The death returns showed that there was immediately preceding the outbreak of plague a slightly increased mortality from what was certified as pneumonia in the coolie location and the adjacent district of Burghersdorp. This was not altogether unanticipated either by the medical faculty or the health authorities since there had been three weeks of unprecedented wet, misty weather succeeded by a sudden fall in the temperature and cessation of rain.

The Present Epidemic.

Nothing of an alarming nature was brought before the health authorities of Johannesburg until the evening of March 18th, 1904, when the health inspector of the municipality informed the district surgeon of Johannesburg that he had found in the coolie location a large number of sick persons collected together. The assistant district surgeon was instructed to visit the place in question and he reported to the district surgeon that he found a number of sick Asiatics suffering from what appeared to him to be pneumonia in a house in the coolie location. At 6.30 A.M. on March 19th the district surgeon, the acting medical officer of health of Johannesburg, and the assistant bacteriologist for the Transvaal visited the house in the location. They found five corpses and 12 cases of sick in a four-roomed house.

The post-mortem examinations revealed nothing which could not be explained by death from pneumonia. There was not a single classical symptom of death from plague; the spleens were not enlarged and were not markedly hyperæmic; there were no ecchymoses or hæmorrhages; the organs, with the exception of the lungs, were normal. The lungs showed patchy pneumonic consolidation of the lobular type and although a very careful search was made for enlarged glands none were found. It is to be remarked that not even a single bronchial gland was found. Portions of the lung on bacteriological examination showed organisms morphologically identical with the plague bacillus. Owing to the insanitary condition of the coolie location and to the large and unknown number of cases in that location it was decided to cordon the whole area in order, if possible, to keep the actually infected people within a limited area. The cordon was formed at 4 A.M. on March 20th and on the same day at 9 A.M. an emergency meeting of members of the Johannesburg town council was held, when the acting medical officer of health and the district surgeon were instructed to take all necessary steps. By 9 A.M. on March 20th further deaths had taken place, making a total of 26 deaths in 36 hours. It is to be remarked here that not a single case of these showed any signs of buboes. On March 22nd the Government published plague regulations and constituted the Rand Plague Committee, composed of ten members from Johannesburg and representatives from the various local authorities within the Witwatersrand area. This committee was given plenary powers to deal with the outbreak within that area and to establish plague and isolation camps.

One of the first decisions arrived at by the plague committee was to remove the whole of the population of the coolie location to some site outside the town and the transfer of the population within the cordoned area to the segregation camp was completed on March 30th. This population consisted of 1600 Asiatics, 1358 natives, and 142 coloured people, making a total of 3100 transferred to the segregation camp. During the incubation period of the disease only one death from plague occurred. After 12 days' interval the inhabitants of the segregation camp were allowed to come and go under certain nominal restrictions. On April 8th the coolie location was burned to the ground. In order to prevent the escape of rats, cats, dogs, fowls, and other creatures a galvanised iron fence was put up round this location and the various animals and birds which had not been previously caught and destroyed were then caught, killed, and burnt in the fire.

Methods Adopted for Coping with the Epidemic.

The plague committee has carried out in the main the recommendations of the Durban Plague Congress. "Contacts" are not segregated; so far as possible they are kept under observation but their movements are limited to the least possible extent. "Suspects" are isolated as such in a suspect camp adjoining the plague camp at Rietfontein; with the exception of the medical officers the suspect and plague camps at Rietfontein are treated as separate entities. So far as possible the methods adopted are early notification, removal and complete disinfection of all suspects, and observation of contacts. The natives working on the mines within the Witwatersrand area are inspected daily by the compound managers and any natives who are found to be sick are at once examined by the mine medical officer. It has been made compulsory upon all employers of natives to have every sick native medically examined within 24 hours of his falling sick. In order to minimise the spread of the disease no Asiatic is allowed to travel by rail, even within the limits of the colony, unless he receives a clean bill of health from the medical examining officer. During the period from March 29th to April 19th there have been 14,010 natives brought under medical observation and one case of plague and seven suspects have been detected and transferred either to the plague or suspect hospital. The total number of deaths from plague recorded from March 18th to April 23rd in Johannesburg district and the Rand area was 76—namely, eight whites, 52 Asiatics, and 16 natives. How the disease originated has not yet been discovered but the following may be accepted as established facts: (1) There has not been up to the present moment anything approaching an epizootic; (2) it is unlikely that there were more than one or two bubonic cases preceding the epidemic for the reasons above mentioned unless there had been unrecognised cases of pestis minor; and (3) the disease might not have been diagnosed for many days after March 18th had there not been a sudden explosion which from a scientific point of view was almost as interesting as it was alarming.

ÉTABLISSEMENT HIVERNAL ET THERMO-MINÉRAL D'HAMMAM-R'HIRA (ALGÉRIE).

BY D. W. KEILLER MOODY, M.D., C.M. ABERD.

IN December, 1903, I was sent in charge of a patient who was ordered to winter in Algiers. While there, and on the advice of Dr. A. Thompson, the resident English medical man, I went to Hammam R'Hira to see the baths. I had never before heard of the place and I believe there are hundreds of medical men who can say the same. It has, however, been visited by several eminent medical men, and among others by the late Sir Morell Mackenzie, by Sir Lauder Brunton,[1] by Mr. G. D. Pollock who says: "I know of no place offering similar advantages within the same distance and as accessible to London"[2]; and by Dr. R. A. Gibbons who writes: "In mentioning the claims of Hammam R'Hira I am influenced by the fact that we have no place like it, or which can be in any way compared with it in this country or on the continent."[3] But as far as I can learn nothing has been written about it in English medical journals for many years. I propose, therefore, to give a brief account of my own personal experiences of the place, which I trust may be of service to those of my brother practitioners who have never had the opportunity of visiting it themselves and who may be glad to hear of a spot where there is perpetual sunshine and which is only three days' journey from London.

---

[1] Practitioner, April, 1881.

[2] THE LANCET, March 5th, 1881, p. 362.

The best and quickest way to get to Hammam R'Hira is to travel *viâ* Paris to Marseilles and thence by means of the steamers of the Compagnie Transatlantique. They are about 2000 tons register and sail four times a week for Algiers, doing the journey across in about 26 hours. Those who do not care for the overland route and to whom time is no object can have a choice of several ways. They can go by either the Peninsular and Oriental or the Orient-Pacific steamship companies' vessels to Marseilles or Gibraltar and tranship at either of those places, or they can go direct to Algiers by the vessels of the British India Steamship Company. A night will have to be spent in Algiers and next day a three or four hours' journey by rail (according to train) to Bou-Medfa, 60 miles distant, will have to be taken, where a carriage from the hotel meets travellers, and thence there is a drive of one and a half hours through beautiful scenery which reminded me of the Highlands of Scotland, New Zealand, and the Rockies of America—really a combination of the whole three. The hotel is a very fine one, equalling any to be found on the continent of Europe. It is of immense size, cost a large sum to build, and is replete with every comfort for the invalid. It stands on the top of a hill 3000 feet above the sea level and is surrounded by a pine forest of 1800 acres and beautiful gardens and orange and lemon groves. It has the distinct advantage of being "Far from the madding crowd." No trippers or tourists are to be found here—the place is too quiet for them. Here also patients have no temptation to run contrary to the orders of their medical advisers. The tariff is such as to come within reach of those whose means are limited, the charges being from 11 francs per diem inclusive of wine and also the natural mineral waters.

I would recommend all who think of trying the place to go there between Feb. 1st and the end of April. Then one can be absolutely sure of continuous fine sunny weather. It is, however, open from Dec. 1st to June 1st. In December, however, I found it rather cold, especially in the morning and evening—the kind of weather one often meets with in the South of France.

The baths were known even to the Romans who built a town round them, remains of which are being continually unearthed. The Moors, who have separate baths, have great faith in them and theirs are constantly in use. The French, also recognising their therapeutic value, have established a military hospital close by. The baths are two large swimming ponds situated in the basement of the building and measuring 15 by 30 feet. The temperature in bath No. 1 is from 90° to 93° F. and in bath No. 2 from 104° to 110°, the reason for the difference being that the water in bath No. 2 comes direct through pipes from its source in the rocks, which is 200 yards away, whereas the water in bath No. 1 is merely the overflow from bath No. 2 The supply is very plentiful and as each bath fills it simply overflows. The constant flow thus insures cleanliness. Like Dr. R. Ottewell-Gifford Bennett,[4] on going into bath No. 2 I felt a scalding sensation which made me at once withdraw my leg. I, however, persevered and soon got used to the heat. One stays in each bath about ten minutes or as the physician orders. The waters are in their composition very similar to those of Bath. For those who so desire there are private baths, hot and cold douches, jets, shower bath, &c. Analysis of the hot springs shows that one litre of water contains:—

Carbonate of lime	0 207	Chloride of potassium ...	0 091
Carbonate of magnesium	0 030	Silicate of sodium	0 069
Sulphate of lime	1·303	Alum	0 002
Sulphate of magnesium	0·172	Peroxide of iron	Trace.
Sulphate of sodium ...	0 017		
Chloride of sodium ...	0 439	Total	2·330

Besides the baths there is also a cold aerated mineral water which contains saline and ferruginous salts and is of a pleasant taste. The iron is in such small quantity that one does not taste it. The water mixes well with claret or other light wines. Analysis of it is as follows:—

Free carbonic acid	0 8820	Sulphide of sodium ...	0 3425
Bicarbonate of lime ...	0 9411	Chloride of sodium ...	0 2801
Bicarbonate of magnesium	0 0314	Chloride of potassium ...	Trace.
Bicarbonate of strontium	Trace.	Silicate of sodium	0 0240
Bicarbonate of manganese	0 0008	Alum	0 0028
Bicarbonate of iron ...	0 0400	Organic matter	Trace.
Sulphide of calcium ..	0 5338	Arsenic and phosphoric acids	Trace.
Sulphide of magnesium	0 1623	Total	3 2408

These baths are undoubtedly of great service in the treatment of chronic rheumatism and gout, both muscular and articular. They are undoubtedly of great service also in neurasthenia, neuralgia, scrofula, hepatic and renal diseases, certain forms of paralysis (my attention was drawn to the remarkably good results obtained in an early case of locomotor ataxia), and some chronic uterine affections. The mineral waters are very useful in anæmia, dyspepsia, hepatitis, and constipation; they have also been recommended in cases of renal calculus. In early cases of pulmonary consumption this is an excellent place on account of its equability of temperature, its dryness, and its fairly high altitude

There is plenty of outdoor exercise for those who are physically intact. Horse riding through a beautiful and hilly country is to be had, while tennis, croquet, cricket, and beautiful drives and walks are available for those so inclined. In the way of sport there are plenty of hares, rabbits, partridge, quail, and wild boar to be had, with perhaps an occasional panther. There is a long verandah (100 yards) where patients can sit the whole day and the hotel provides an excellent band. From what I have seen of the place I can honestly recommend it. "We live in a nervous age." I consider it an excellent place for those suffering from "brain fag," of which so much has been heard lately.

---

[4] Extracts from the Journal of British and Foreign Health Resorts, March, 1891.

MR. ION PERDICARIS AND SANITARY REFORM AT TANGIER.

THE capture of Mr. Ion Perdicaris and Mr. Cromwell Varley by the brigand Raisuli is a matter of more than ordinary and personal concern. Tangier is within five days' journey from London. It possesses so many natural and climatic advantages that its popularity as a health resort was likely to increase more and more. From time to time we have described some of these advantages.[1] Morocco, however, belongs to decadent Moors and to more or less wild and savage tribes of Berbers, Riffians, Bedouins, and a sprinkling of negroes from the Soudan. These people feel that they cannot compete against European mechanical appliances and manufacturing processes. Consequently they have very consistently and logically resisted to the uttermost any attempt to Europeanise their country. The Sultan himself has been won over to European ideas. He takes interest in photography, motor-cars, and other contrivances calculated to disturb the contemplative repose that suits so well the dignified Moor. Therefore the people have taken alarm and have rebelled against their Sultan. A sort of civil war has prevailed for now more than two years. Thus the hope that Tangier and perhaps other places on the coasts of Morocco might become useful resorts for the climatic treatment of disease has been thrown back indefinitely unless it be that night is darkest just before daybreak.

The fact is that considerable progress, to use the term in a European sense, had been accomplished of late years at Tangier. Under the leadership of Mr. Ion Perdicaris the European residents had constituted themselves into a sort of borough, elected a municipality, and duly proceeded to impose taxes on each other. They used the money thus collected to build some sewers, to pave some streets, and in fact to introduce sanitary improvements which rendered the place more inhabitable. Therefore, more visitors came, land increased in value, and so many new and European houses were built that had this continued the picturesque character of the place would soon have been destroyed. Then people would cease to go to Tangier and then all this building would have proved useless and a dead loss. But the Moors rebelled. They did not, perhaps, greatly object to the improvements made at Tangier, particularly as for the moment it brought in a golden harvest, but they could not tolerate European ideas at the court of their own Sultan and in the interior of the country. Little by little the Sultan has lost his authority and the country has fallen into a state of anarchy. The culminating point of this disorder is surely reached when so respected a resident as Mr. Perdicaris can be surrounded and captured in his own house, though it is situated but three miles from the embattled walls of Tangier. It is not probable that even Raisuli and his wild men would willingly do Mr. Perdicaris or Mr. Varley any bodily injury, but Mr. Perdicaris is not in good health and at his age the rough existence he will be forced to lead may produce evil results. Perdicaris all his life has been devoted to good deeds. No one could be more popular among the Moslem Moors whom he has defended over and over again from the extortions of Jew and Christian usurers, acting under the cover of the *protégé* system. It will go hard with Raisuli and his tribe if they injure him. To the European Mr. Perdicaris has also been a constant friend and the leader in all practical useful works. It was Mrs. Perdicaris who organised the soup kitchens when there was danger of cholera, so that the want of food should not prepare the way for the outbreak of the disease. In all public works that have contributed to render Tangier clean and healthy Mr. Perdicaris was the principal initiator and donor. The cause of public health has in him its first and most useful champion, while in regard to the cruel abuses practised under the *protégé* system he has been instrumental in bringing about reforms. We cannot believe him in danger, but the episode is none the less disconcerting, as other Europeans not well-known and respected may be similarly treated. What is so pleasant and health restoring at Tangier is the facility for obtaining horses and mules, or even camels if preferred, and going for long rides over the hills and wild roadless country. With Raisuli and his men on the warpath this is evidently not possible now. If they do not respect even Mr. Perdicaris certainly no one else is safe. In these circumstances, and in view of the treaty recently concluded between England and France, it may well be that this is the beginning of the end. The European intervention so long deferred may soon be at hand. It will not be an unmixed blessing. It may put an end to the special charm that Morocco possessed which was useful, not only to the artist in search of the original and beautiful, but also to the physician anxious to provide a complete mental change for his patient. On the other hand, it will be more easy to get the necessary sanitary works carried out and it is to be hoped that brigandage will be suppressed. Thus the ordeal Mr. Perdicaris is now enduring may prove beneficent to the community among whom he has lived for more than 30 years. It will have served, in any case, to show him how extensive and profound is the admiration his life's work has evoked. The press throughout Europe and America and his numerous personal friends have manifested the keenest sympathy and appreciation, and this also should give strength and consolation to his wife and family during this moment of trial and danger.

[1] THE LANCET, May 7th, 1897, p. 955, and June 18th, 1898, p. 1721.

THE MEDICAL, SURGICAL, AND HYGIENIC EXHIBITION.

THE eighth annual exhibition was opened in the Queen's Hall, Langham-place, W., on May 24th. The fact that this annual exhibition has now reached its eighth year shows that a very general interest in it on the part of visitors has been maintained, and judging from the attendance of medical men, hospital nurses, and others it has evidently supplied a distinct want to those whose opportunities of inspecting the latest examples of progress in regard to drugs, foods, and medical and sanitary appliances are limited to exhibitions that take place within the metropolitan area. It is not surprising, therefore, that disappointment was generally expressed at the fact that the number of exhibits this year was decidedly smaller than on previous occasions, though in one or two sections there was a slightly increased representation. With few exceptions the examples of food preparations shown were quite well known to the profession and a great many of the exhibits comprising drugs were also familiar. In the sanitary section there were some novelties which we may briefly notice.

The preparation of the Denver Chemical Manufacturing Co. (110, Cheapside, London, E.C.) known as antiphlogistine was well represented. We have already pointed out in our analytical columns the composition of antiphlogistine. As a preparation for use externally in inflammatory conditions it has the advantage of being at the same time an antiseptic, a non-conductor of heat, and a vaso-motor stimulant. It is, in fact, a considerable advance on the ordinary poultice, its composition being based upon a better knowledge of the condition and requirements of swollen and sensitive tissues. It further possesses physical advantages over old methods and the theory of its therapeutic action is sound. Messrs. Burgoyne, Burbidges and Co. (12 and 16, Coleman-street, London, E.C.) exhibited an interesting series of preparations, including Von Heyden's pharmaceutical products. Amongst the latter may be mentioned creasotal (creasote carbonate) and duotal (guaiacol carbonate), which while exerting powerful germicidal effects are non-poisonous and non-corrosive and may therefore be safely administered internally. These preparations have been used with considerable benefit in the early stages of phthisis. The exhibit included some interesting antiseptic preparations of silver and acoine, a local anæsthetic of some repute. Ovo-lecithin (Billon, 16, Water-lane, Great Tower-street, London, E C.) has already been described in our columns since which further experience has been gained of its value in disorders of nutrition, neurasthenia, and the like. The exhibit included examples of therapeutic serums and calf vaccines prepared by the Institut Pasteur (Lille, France). The serums exhibited were antivenum serum, antitetanus serum, and anti-diphtheritic serum. The Angier Chemical Co. (32, Snow-hill, London, E.C.) exhibited its emulsion and throat tablets; the composition of both preparations is based upon a specially purified petroleum. It is probable that the petroleum acts as a vehicle, while no doubt it is a sedative and demulcent and therefore is useful in inflamed or ulcerated conditions. The emulsion consists of petroleum with hypophosphites of lime and soda and pure glycerine. Messrs. C. de Trey and Co. (52, Shaftesbury-avenue, London, W.C.) exhibited specimens of somnoform manufactured by Mr. A. Rousseau, Bordeaux, which is described as a quick, simple, and safe anæsthetic. It consists of 60 per cent. of chloride of ethyl, 35 per cent. of chloride of methyl, and 5 per cent. of bromide of ethyl. It is said to have no action on the heart and not to produce asphyxia or cyanosis nor seriously to disturb respiration. Messrs. F. Newbery and Sons (27 and 28, Charterhouse-square, London, E.C.), exhibited the well-known pharmaceutical preparations of Messrs. W. R. Warner and Co., the list including an excellent series of granular effervescent salts and the malt preparations of Professor Trommer. Messrs. Cooper and Co. (80, Gloucester-road, South Kensington, London, W.) had a very attractively decorated stall on which were displayed their pure oxycarbonated mineral waters in porcelain-lined syphons as well as in ordinary bottles. The waters are prepared under pressure of both carbonic acid and oxygen gases, very pure distilled water being employed for the purpose. Besides soda, seltzer, and potash waters the following drugs may be employed in this pure aerated water: lithia, lisidin, lycetol, phenocoll, piperazine, and urotropine. The exhibit included a very excellent emulsion of cod-liver oil with lactophosphates and a preparation also of oxy-carbonated fluid magnesia.

As has already been said, many of the food preparations were old and trusted friends as, for example, the preparations of the Peptenzyme Co., the Marmite Food Extract Co., the Shredded Wheat Co., Maltova, Limited, the Protene Co., the Maltine Manufacturing Co., Messrs. Van Abbot and Sons (diabetic foods), International Plasmon, Limited, Mr. Henry Nestlé (condensed milk and food), Messrs. Cadbury Bros. (cocoa), Messrs. Callard and Co. (starchless foods), Bovril, Limited, and Virol, Limited, the Hovis Bread and Flour Co., Cerebos, Limited, Liebig's Extract of Meat Co., and the Anglo-Swiss Milk Co. A comparatively recent introduction, however, is the preparation known as "galak" dried milk of the "Galak" Milk Products Co. (118, Fenchurch-street, London, E.C.). In this process milk is distributed thinly and evenly between heated cylinders and emerges in a thin, slightly damp film which dries on cooling. The film is then passed through sieves by which it is reduced to a white flaky or granulated powder. On analysis it shows the composition of complete milk solids, including the whole of the fat. The preparation is said to be sterile and to give excellent physiological results. The preparation seems to be an important innovation, but evidence is wanted, we think, as to whether it possesses the anti-scorbutic properties of raw milk. Judging from the method of preparation, in which considerable heat is employed, it is not possible to conceive that the milk powder when dissolved in water has the same physiological properties as fresh uncooked milk.

Sanitary preparations were fairly well represented and amongst novelties may be mentioned the sphagnol preparations of the Peat Products Co. (71A, Great Russell-street, London, W.C.). Sphagnol is described as a combination of the antiseptic and emollient vegetable tars and oils obtained by the distillation of peat. It has been used with advantage in skin diseases. Amongst other preparations containing sphagnol were suppositories which are said to be serviceable in hæmorrhoids, an ointment used in eczema, a soap for ringworm, and other preparations helpful in the treatment of many conditions. The Pearson's Antiseptic Co., Limited (254A, High Holborn, London, W.C.), exhibited a number of antiseptic preparations which possess merits already pointed out in our analytical columns. The Jeyes' Sanitary Compound Co., Limited (64, Cannon street, London, E.C.), exhibited a number of antiseptic preparations the basis of which is "cyllin," formerly known as creolin. Bacteriological experiments have shown this coal-tar disinfectant to be a powerful germicide, whilst its toxic and caustic properties are relatively inappreciable. Similar claims are made for izal, which is the basis of a number of disinfectant preparations made by Messrs. Newton Chambers and Co. (Thornecliffe, near Sheffield). Petol, Limited (86, Cannon-street, London, E.C.), exhibited a number of articles, such as soaps, ointments, and suppositories, containing petol which is described as a vegetable base derived from peat. As an antiseptic and healing agent it has been employed in skin diseases.

A considerable assortment of surgical and hospital appliances was exhibited by the Holborn Surgical Instrument Co. (26, Thavies Inn, Holborn-circus, London, E.C.), while the Hospitals and General Contracts Co. (33, Mortimer-street, London, W.) exhibited aseptic aluminium tables for operating theatres or wards, besides also some sterilisers, one form being heated by means of the electric current. The Sanitary Wood Wool Co. (26, Thavies Inn, Holborn-circus, London, E.C.) exhibited its wood-wool preparations and the Cellular Clothing Co., Limited (72 and 73, Fore-street, London, E.C.), submitted to view various applications of its aertex cellular cloth; this material is porous besides being an excellent insulator. Mineral waters were represented in the exhibit of Camwal, Limited (112, Pembroke-street, Caledonian-road, London, N.), and in a very excellent display of pure waters prepared with great care as regards purity by Idris and Co. (Camden Town, London, N.W.). Arabella water has been comparatively recently introduced by Arabella, Limited (2, Hay-hill, Berkeley-square, London, W.). A feature of this water is that while it contains a large proportion of the sulphates of sodium and magnesium it is not so objectionable to the taste as are many bitter purgative waters. Amongst electrical apparatus may be mentioned the Gaiffe coil with the Carpentier-Gaiffe platinum interrupter shown by the Medical Supply Association (228, Gray's Inn-road, London, E.C.), and high-frequency and x-ray apparatus by Harry W. Cox, Limited (9, 10, and 11, Cursitor-street, Chancery-lane, London, W.C.). An interesting exhibit was that of Reinheimer and Co. (Surbiton, Surrey), who showed specimens of non-alcoholic wines which not long ago were analytically examined with favourable results in THE LANCET laboratory. Messrs. Greenlees Bros. (29 and 31, Commercial-street, London, E.) exhibited a miniature model of a pot still, but we could not gather whether they made any special claim for their whiskies as being all malt or blends.

Finally, several well-known medical publishers exhibited examples of recent medical and surgical literature on their stalls.

Looking Back.

FROM

THE LANCET, *SATURDAY*, May 27, 1826.

FOREIGN DEPARTMENT.

Discovery of Two Canals in the Vagina and Uterus. By Dr. GARTNER, of Copenhagen.—(*Annali Univ. di Med., March*, 1826.)

Dr. Gartner, in dissecting the uterus of the cow, found two singular canals, of which modern anatomists make no mention. They commence in the neighbourhood of the fallopian tubes, and open into the vagina near the meatus urinarius. They exist also in the sow; neither age nor gestation makes any difference; they are always present. In the sow, these canals commence by two openings situated on the sides of the orifice of the urethra, run obliquely from within outwards in the substance of the parietes of the vagina, and also a little upwards, thus describing a curve; in this course they receive lateral branches, coming from the neighbouring glands, the union of which forms a mass rather analogous in its external appearance to the pancreas; they diminish successively in size as they receive fewer of these small lateral ducts, and especially in the part of the parietes of the vagina which is continuous with the cornua of the uterus. They are always present, but their appearance varies; they appear more developed a short time after conception. In a sow, the uterus of which enclosed some fœtuses from two to three inches in length, the diameter of these canals was more considerable, and they extended, even in the substance of the broad ligaments, to within a few inches from the ovaries, where they apparently terminated in several small glandular granulations. The prolongation of these canals in the broad ligaments was very evident; their appearance was white and opaque, but it was easy to inject them with quicksilver; in some points they were considerably contracted, and appeared in some others completely obliterated.

In the cow, the vaginal orifice of these canals is larger, situated more in front, on the side of the meatus urinarius; these canals are continued the whole length of the lateral parietes of the vagina, nearly to a level with the orifice of the uterus, where they appeared all of a sudden to terminate; but an attentive examination showed, that they penetrate into the substance of the tissue of the neck of the artery, and re-appear on the uterus, on the surface of which, they, as it were, insensibly recover their existence, and are continued superiorly to the cornua of the uterus, and along their surface, to within a few inches from the ovaries. These vessels, or canals, are invariably to be found in the course which we have just mentioned. In some young cows, the uterine portion of these canals is so extremely fine, that it appears impermeable; in others, on the contrary, it is more or less dilated, and filled with a gelatinous and tenacious fluid, which presented the appearance of hydatids in the small dilatations. The portion of these canals which corresponds to the neck of the uterus is subject to several varieties, resulting principally from the age and the state of the gestation of the animal. The vaginal and uterine portions are both generally isolated, but the communication appears to be established through the medium of small glandular bodies, situated on the neck of the artery; sometimes, instead of these granulations, a real canal, laterally dilated, is found, in the parietes of which numerous vessels ramify, bearing some analogy to a common excretory duct. This disposition is very apparent in the adult cow. The distensions of a glandular appearance which are observed in this region, are sometimes very prominent, and filled with a gelatinous fluid. It is very rare that the canals which we have just described are alike in both sides of the neck of the uterus; most frequently a duct is found on one side only, and on the other glandiform granulations.

It is very probable that these two canals, or to use a better expression, these two organs, exert some influence on conception. Galen (in the article entitled, *de dissect. vulva* ch. ix.) appears to indicate something analogous to this anatomical fact. De Graaf (*opera omnia*) probably suspected the existence of similar organs in the uterus of the woman; perhaps the fasciculi of muscular fibres found by M. le Baron Cuvier in the cow, extending from the ovaries to the neck of the uterus, bears some relation to these canals. Haller says nothing precise on the subject, but Malpighi (Epist ad Spont. p. 26.) expresses himself in such a manner, as to induce him to think that he understood these organs.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8570 births and 4532 deaths were registered during the week ending May 21st. The annual rate of mortality in these towns, which had been 16·3, 14·9, and 16·1 per 1000 in the three preceding weeks, had declined again to 15·5 per 1000 last week. In London the death-rate was 15·1 per 1000, while it averaged 15·6 per 1000 in the 75 other large towns. The lowest death-rates in these towns were 6·9 in Northampton, 7·1 in Hornsey, 7·9 in Handsworth (Staffs.), 8·0 in Walthamstow, 9·4 in King's Norton, 9·6 in Reading, 10·1 in Plymouth, 10·5 in Croydon, and 10·6 in Willesden; while the highest rates were 19·6 in Manchester, 20·0 in Leeds, 20·4 in Preston, 20·5 in Blackburn, 20·6 in Tynemouth, and 21·7 in Norwich and in Birmingham. The 4532 deaths in these towns last week included 528 which were referred to the principal infectious diseases, against 527, 514, and 525 in the three preceding weeks; of these 528 deaths 182 resulted from measles, 182 from whooping-cough, 57 from diarrhœa, 45 from diphtheria, 30 from scarlet fever, 28 from "fever" (principally enteric), and four from small-pox. No death from any of these diseases was registered last week in Hastings, Bournemouth, Reading, Ipswich, Aston Manor, Wigan, Stockton-on-Tees, or Tynemouth; while among the other towns the highest death-rates from the principal infectious diseases were recorded in Brighton, Birmingham, Warrington, Manchester, Salford, Burnley, Blackburn, and Leeds. The greatest proportional mortality from measles occurred in Croydon, Walthamstow, Brighton, Manchester, Burnley, Leeds, and Hull; from scarlet fever in Hanley and in Warrington; from diphtheria in Great Yarmouth and in Merthyr Tydfil; and from whooping-cough in Birmingham, Coventry, Grimsby, Derby, Birkenhead, Warrington, Bury, Salford, Blackburn, and Leeds. The mortality from "fever" and from diarrhœa was not excessive in any of the large towns. Of the four fatal cases of small-pox registered in these towns last week one belonged to Nottingham, one to Oldham, one to Gateshead, and one to Cardiff. The number of small-pox patients remaining under treatment in the Metropolitan Asylums hospitals, which had been 104, 88, and 99 on the three preceding Saturdays, had declined again to 96 on Saturday last, May 21st; 18 new cases were admitted during the week, against 12, 14, and 26 in the three preceding weeks. The number of scarlet fever cases in these hospitals and in the London Fever Hospital was 1630 at the end of last week, against 1541, 1590, and 1600 at the end of the three preceding weeks; 222 new cases were admitted during the week, against 185, 242, and 239 in the three preceding weeks. The deaths in London referred to pneumonia and diseases of the respiratory system, which had been 224, 193, and 231 in the three preceding weeks, had declined again to 210 at the end of last week and were 26 above the number in the corresponding period of last year. The causes of 63, or 1·4 per cent., of the deaths in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Bristol, Bolton, Leeds, Newcastle on-Tyne, Cardiff, and in 43 other smaller towns; the largest proportions of uncertified deaths were registered in Portsmouth, Reading, Norwich, Birmingham, Liverpool, St. Helens, Manchester, Rochdale, Blackburn, Sheffield, and Gateshead.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 20·0, 18·0, and 17·9 per 1000 in the three preceding weeks, increased again to 18 7 per 1000 during the week ending May 21st, and was 3·2 per 1000 in excess of the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 13·0 in Leith and 16·2 in Aberdeen, to 20·0 in Perth and 23·2 in Greenock. The 619 deaths in these towns included 21 which were referred to whooping-cough, 16 to measles, 13 to diarrhœa, four to scarlet fever, two to small-pox, and two to diphtheria, but not any to "fever." In all, 58 deaths resulted from these principal infectious diseases last week, against 71, 64, and 75 in the three preceding weeks. These 58 deaths were equal to an annual rate of 1·8 per 1000, which was also the mean rate last week from the same diseases in the 76 large English towns. The fatal cases of whooping-cough, which had been 22, 25, and 28 in the three preceding weeks, declined again last week to 21, of which ten were recorded in Glasgow, four in Aberdeen, three in Edinburgh, and three in Dundee. The deaths from measles, which had been 16 and 17 in the two preceding weeks, declined again to 16 last week and included 10 in Glasgow and three in Greenock. The fatal cases of diarrhœa, which had been 13, nine, and 15 in the three preceding weeks, decreased again last week to 13, of which seven occurred in Glasgow and three in Dundee. The four deaths from scarlet fever corresponded with the number in each of the two preceding weeks and included three in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 121, 100, and 90 in the three preceding weeks, rose again last week to 97, but were slightly below the number in the corresponding period of last year. The causes of 22, or nearly 4 per cent., of the deaths registered in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 20·8, 23·1, and 21·6 per 1000 in the three preceding weeks, rose again to 21·9 per 1000 during the week ending May 21st. During the past four weeks the death-rate in Dublin has averaged 21·9 per 1000, the rates during the same period being 15 5 in London and 17·4 in Edinburgh. The 159 deaths of persons belonging to Dublin registered during the week under notice were slightly in excess of the number in the preceding week and included 13 which were referred to the principal infectious diseases, against eight, 18, and 17 in the three preceding weeks; of these, five resulted from whooping-cough, two from measles, two from "fever," two from diarrhœa, one from scarlet fever, and one from diphtheria, but not any from small-pox. These 13 deaths were equal to an annual rate of 2·0 per 1000, the death-rates last week from the same diseases being 1·7 in London and 0 9 in Edinburgh. The fatal cases of whooping-cough, which had been three, 11, and ten in the three preceding weeks, further declined last week to five. The deaths from measles, which had been two, four, and two in the three preceding weeks, were again two last week. The fatal cases of "fever," which had been one, two, and three in the three preceding weeks, declined again last week to two. The 159 deaths in Dublin last week included 20 among children under one year of age and 41 among persons aged 60 years and upwards; the deaths both of infants and of elderly persons showed a considerable decline from the respective numbers recorded in the preceding week. Five inquest cases and three deaths from violence were registered, and 66, or more than two-fifths, of the deaths occurred in public institutions. The causes of three, or nearly 2 per cent., of the deaths registered in Dublin last week were not certified.

VITAL STATISTICS OF LONDON DURING APRIL, 1904.

IN the accompanying table will be found summarised complete statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs. With regard to the notified cases of infectious diseases it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to an annual rate of 5·1 per 1000 of the population, estimated to be 4,648,950 persons in the middle of the year. In the three preceding months the rates had been 5·1, 4·8, and 4·9 per 1000 respectively. The rates were considerably below the average in Paddington, Kensington, Chelsea, the City of Westminster, Hampstead, and Woolwich; while they showed the largest excess in Finsbury, Shoreditch, Bethnal Green, Stepney, and Poplar. The prevalence of small-pox during April was slightly less marked than it had been in the preceding month; among the various metropolitan boroughs this disease was proportionally most prevalent in St. Marylebone, Stoke Newington, Shoreditch, Bethnal Green, Stepney, Poplar, and Bermondsey. The Metropolitan Asylums hospitals contained 104 small-pox patients at the end of last month, against 21, 31, and 126 at the end of the

ANALYSIS OF SICKNESS AND MORTALITY STATISTICS IN LONDON DURING APRIL, 1904.

* Including membranous croup.

three preceding months; the weekly admissions averaged 24, against four, six, and 31 in the three preceding months. During the period under notice no fewer than 2000 cases of chicken-pox were notified in London. Scarlet fever showed a slightly increased prevalence last month, the greatest proportional prevalence occurring in St. Pancras, Finsbury, Shoreditch, Bethnal Green, Stepney, Bermondsey, and Deptford. The number of scarlet fever patients under treatment in the Metropolitan Asylums hospitals, which had been 1626, 1560, and 1546 at the end of the three preceding months, had further declined to 1515 at the end of April; the weekly admissions averaged 173, against 182, 153, and 160 in the three preceding months. The prevalence of diphtheria was rather greater during April than in the preceding month; among the various metropolitan boroughs this disease was proportionally most prevalent in St. Pancras, Hackney, Bethnal Green, Poplar, Wandsworth, and Greenwich. The Metropolitan Asylums hospitals contained 718 diphtheria patients at the end of last month, against 752, 782, and 786 at the end of the three preceding months; the weekly admissions averaged 97, against 97, 107, and 94 in the three preceding months. Enteric fever, which had shown a continuous decline in the four preceding months, was still further reduced during April; the greatest proportional prevalence of this disease was recorded in St. Marylebone, Hackney, Holborn, Finsbury, Poplar, and Wandsworth. The number of enteric fever patients in the Metropolitan Asylums Hospitals, which had been 246, 166, 125, and 86 at the end of the four preceding months, had further declined to 62 at the end of last month; the weekly admissions averaged nine, against 30, 16, 15, and 11 in the four preceding months. Erysipelas was proportionally most prevalent in Hammersmith, St. Marylebone, the City of London, Southwark, Bermondsey, and Deptford. The 15 cases of puerperal fever notified during the month included two in Lambeth and two Camberwell.

The mortality statistics in the table relate to the deaths of persons actually belonging to the various metropolitan boroughs, the deaths occurring in public institutions having been distributed among the various boroughs in which the deceased persons had previously resided. During the four weeks ending April 30th the deaths of 5784 persons belonging to London were registered, equal to an annual rate of 16·2 per 1000; in the three preceding months the rates had been 17·2, 18·2, and 16·7 per 1000. The lowest death-rates in London last month were 9·6 in Hampstead, 12·3 in Paddington, 13·0 in Greenwich and in Lewisham, 13·1 in Wandsworth, 13·2 in the City of Westminster and in Battersea; and 13·4 in Stoke Newington; the highest rates were 20·0 in Poplar, 20·7 in Bermondsey, 20·8 in Shoreditch, 21·7 in the City of London, 22·8 in Southwark, and 23·1 in Finsbury. The 5784 deaths from all causes in London last month included 684 which were referred to the principal infectious diseases; of these, seven resulted from small-pox, 308 from measles, 31 from scarlet fever, 53 from diphtheria, 212 from whooping-cough, 13 from enteric fever, one from simple continued fever, and 59 from diarrhœa. The lowest death-rates from these diseases were recorded in Paddington, the City of Westminster, Hampstead, the City of London, Wandsworth, and Lewisham; and the highest rates in Bethnal Green, Stepney, Poplar, Southwark, Bermondsey, Deptford, and Greenwich. Of the seven fatal cases of small-pox registered last month two belonged to Stepney, two to Poplar, and one each to Paddington, Holborn, and Bethnal Green. The 308 deaths from measles were slightly in excess of the average number in the corresponding periods of the ten preceding years; this disease was proportionally most fatal in Hammersmith, St. Marylebone, Stepney, Poplar, Southwark, Bermondsey, and Deptford. The 31 fatal cases of scarlet fever showed a decline of 15 from the corrected average number; among the various metropolitan boroughs the highest proportional fatality from this disease occurred in St. Marylebone, St. Pancras, Islington, Finsbury, and Lambeth. The 53 deaths from diphtheria were less than one-half of the average number in the corresponding periods of the ten preceding years; this disease was proportionally most fatal in Finsbury, Shoreditch, Bethnal Green, Poplar, Southwark, and Wandsworth. The 212 fatal cases of whooping-cough showed a decline of 19 from the corrected average number; among the various metropolitan boroughs the greatest proportional mortality from this disease occurred in Chelsea, Stepney, Southwark, Bermondsey, Camberwell, Deptford, and Greenwich. The deaths from "fever," which had averaged 27 in the corresponding periods of the ten preceding years, numbered only 14 last month; the highest death-rates from "fever" were recorded in Paddington, Hammersmith, Fulham, Islington, Greenwich, Lewisham, and Wandsworth. The 59 fatal cases of diarrhœa were 10 in excess of the corrected average number; among the various metropolitan boroughs this disease was proportionally most fatal in Fulham, the City of Westminster, Finsbury, Deptford, and Greenwich. In conclusion, it may be stated that the aggregate mortality in London last month from the principal infectious diseases was nearly 15 per cent. below the average.

Infant mortality, measured by the proportion of deaths among children under one year of age to registered births, was equal to 118 per 1000. The lowest rates of infant mortality were recorded in Paddington, St. Marylebone, Hampstead, Stoke Newington, and Holborn; and the highest rates in Kensington, Fulham, the City of London, Poplar, Southwark, Camberwell, and Greenwich.

Obituary.

ÉTIENNE J. MAREY,

PROFESSOR IN THE COLLÈGE DE FRANCE, PARIS, AND MEMBER OF THE INSTITUTE.

BY the death of Professor Marey, which took place at Paris on May 16th, the scientific world is the poorer. Physiology has lost one of its brightest ornaments, a worker who did much to extend its boundaries and added much to the means whereby man is enabled to analyse the secrets of nature, and, above all, to investigate the phenomena of motion as manifested in "organised beings." Marey was the occupant of the chair entitled "The Natural History of Organised Beings" in the Collège de France. He was born in 1830 in the department of the Côte d'Or. He, however, pursued his studies in Paris and after competition he became an *interne* in the Paris hospitals. In his thirtieth year in the fiftieth volume of the *Comptes Rendus*, he published a modest but very important paper, entitled "Recherches sur la forme et la fréquence du pouls au moyen d'un nouveau sphygmographe ou appareil enregistreur des pulsations." This same subject formed his graduation thesis. This year marks the invention of Marey's sphygmograph and this invention at once brought his name before the scientific world.

The graphic method was founded before 1850. Ludwig had invented his kymograph. Helmholtz in 1850 had measured the velocity of a nerve impulse in the motor nerve of a frog and previously he had recorded and analysed a muscle curve. Vierordt had made an attempt to record the pulse by means of a complicated heavy instrument constructed of three levers, on the principle, as Marey described it, "of the parallelogram of Watt" which he called a sphygmograph. Vierordt had also tried to estimate the velocity of the blood in the arteries. The kymograph of Ludwig, as Marey pointed out, requires a vivisection. Marey's endeavour was to construct an instrument whereby not only the frequency but also the form of the pulse-wave could be determined. He did so and retained for it the name invented by Vierordt. Vierordt's apparatus on account of its inertia did not follow the changes of form of the pulse-wave at each beat; it gave merely the sequence or frequency of the beats. The use of a light lever applied to an accessible artery and kept applied to it at a given pressure by means of a spring is the principle of the lever of the sphygmograph of Marey who was fortunate in finding in Paris in Breguet, the famous clock-maker, some one to construct the recording apparatus on which the lever made its trace. The graphic method from 1860 onwards was greatly extended by Marey. He applied himself to the study of the phenomena of the circulation and respiratory movements, and invented various forms of cardiograph to record the heart's impulse, manometers to measure the blood pressure, besides pneumographs, stethographs, thermographs, and myographs. By using tambours filled with air which were applied over a moving part—receiving tambours—he was able to transmit movements in tubes filled with air to recording tambours

PROFESSOR E. J. MAREY.

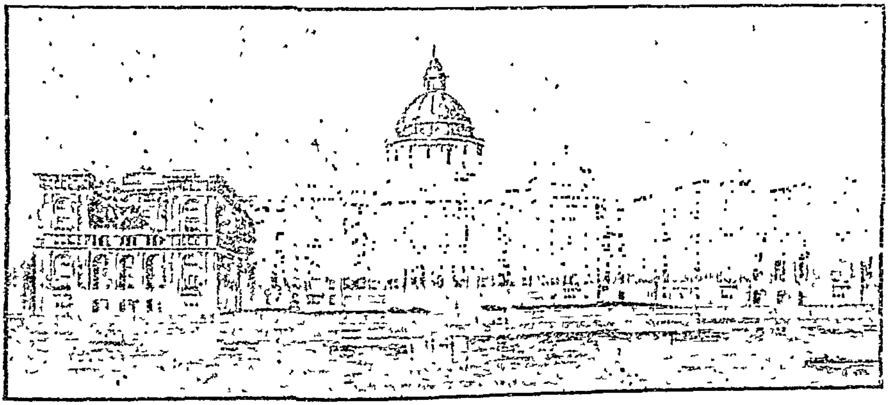
and thus to register movements at a distance. The cardiographic records of the beat of the heart obtained by Marey and Chauveau in 1863 are to be found in every text book of physiology. They introduced a "cardiac sound" through the external jugular vein of a horse and by means of a series of air filled ampullæ were able to record the rate, sequence, force, and duration of the events that make up a cardiac cycle. Thus, as Marey pointed out, movements inaccessible to touch and sight were made visible and could be recorded. Muscular contraction was also studied by means of a simple myograph and so were the movements of man and animals, the mechanism of walking, and all forms of progression; the flight of birds and insects was submitted to accurate scientific analysis by means of this method.

Marey had the great merit of introducing into France the *graphic method in its application to biological problems.* He developed and extended its usefulness and made a method of the laboratory the common property of every clinician and medical practitioner. In 1875 Marey made the important discovery of the refractory period of the heart. Bowditch had shown the phenomenon of the "treppe," or staircase, and had previously defined adequate and inadequate stimuli for the heart by means of a frog manometer. Marey arrived at his results by recording the beat of the frog's heart by means of a special *pince cardiaque.* He published many papers in the various journals and in the *Comptes Rendus.* His works on the "Circulation of the Blood," on "Movement," "Animal Mechanism," and "The Graphic Method" are familiar to every physiologist. He applied the photographic method extensively for the study of movements, as in the flight of birds and progression in man and animals. With him instantaneous photographs became the handmaiden of analytical science.

Marey, although trained as a physician, soon diverted to the study of physiology or at least to that department of it which he cultivated with such success. He was elected to the chair in the Collège de France in 1867 previously held by Flourens, and this enabled him to pursue his studies in his own way. His investigations were made chiefly on physical lines; he left out of count the chemical problems and those of histology. Some years ago he ceased to lecture, though he continued his investigations, his lectures being undertaken by François-Franck. For over a year Marey had but indifferent health; he suffered from gall stones and also from phlebitis. Throughout his illness he, however, still maintained his interest in the affairs of the Collège and in those of the Académie des Sciences. Marey, by his character, by his personal attraction, by his work, by his discoveries, and by his modesty, was a man who was beloved by all who had the pleasure of knowing him. His fame will rest on his successful endeavour to apply the graphic method to the investigation of biological science.

THE PROPOSED NEW BELLEVUE HOSPITAL IN NEW YORK CITY.

BY the courtesy of the editors of the *New York Medical Journal* and of the *Philadelphia Medical Journal* we have been favoured with advance proofs of a description of the proposed new Bellevue Hospital and with an illustration of the same which we reproduce. The following details give the salient points of the proposed building. It is designed to occupy three full city blocks, from Twenty-sixth to Twenty-ninth streets and First Avenue to the East River. It is claimed that it will be the largest, handsomest, and most completely equipped hospital in the world and will accommodate some 2500 patients. Quarters are to be provided for over 100 physicians. The building material is to be Harvard brick with light stone trimmings. The building is to be H-shaped and from the prospectus that has been prepared by the architects is not in general outline unlike the Capitol in Washington. The main part of the building will be 150 feet or more back from the river, and the wings running out on each side will form a large court. The 13 pavilions will be under one roof, but between them will be covered arcades to allow a free circulation of air. Only four of the pavilions will face on First Avenue, and they will be used for the alcoholic, insane, and other psychopathic patients, leaving to the others the benefit of the view and the air on the river. With the exception of the dome over the main part of the building and the curved roofs over four of the pavilions, which the architects, it is said, have added to accentuate the pavilions and to lend architectural support to the dome, all the roofs are flat. Roof gardens will be used by convalescent patients who will be carried directly to the roof in seven elevators. These roof gardens will have temporary wards which will accommodate 100 patients. The roof will be surrounded by a parapet four feet in height. The five upper floors of the south wing will contain the medical wards. The limit of each ward will be 25 patients, but several rooms will be connected with each and may be filled with beds if necessary. The service rooms connected with every ward will be complete and modern in equipment. A pavilion which will be near the present entrance to the hospital will have the three lower floors given over to the ambulance department and carriage house. The upper part will contain the medical amphitheatre with accommodation for 200 students. The five upper floors of the north wing



Eastern front of proposed new Bellevue Hospital.

will contain the surgical wards. The surgical amphitheatre will be equipped with ten small operating rooms all within easy access of the various wards and complete in every detail. The hydropathic department, designed to surpass that of any public or probably even private institution and to contain bathrooms for both employés and patients, will be on the ground floor of the central pavilion. It will be equipped with all modern apparatus for the treatment of disease by water and will be one of the most remarkable new features of the hospital. There will also be an elaborate system of balconies on all sides of the hospital. Each of the 92 wards will have either an open or an inclosed balcony of sufficient size to accommodate all the patients in each ward at one time. Two enormous covered arcades facing the river will accommodate all the patients in the hospital at one time if necessary.

THE SERVICES

Royal Navy Medical Service.

In accordance with the provisions of Her late Majesty's Order in Council of April 1st, 1881, Fleet Surgeon John Dowson has been placed on the Retired List (dated May 14th, 1904) and Fleet Surgeon Henry Harries has been placed on the Retired List at his own request (dated May 21st, 1904).

Royal Naval Volunteer Reserve.

The undermentioned appointments have been made:—Robert Meredith Littler to be Surgeon. Honorary Surgeon Charles O'Brien Harding to be Honorary Staff Surgeon (dated May 17th, 1904).

Royal Army Medical Corps.

Lieutenant N. E. Dunkerton, from the Seconded List, to be Lieutenant (dated May 2nd, 1904). Lieutenant-Colonel R. C. Gunning retires on retired pay (dated May 25th, 1904). Lieutenant-Colonel J. T. Carey retires on retired pay (dated May 25th, 1904). Surgeon-Major W. C. Beevor, C.M.G., from the Scots Guards, to be Major, with seniority next below R J. A. Durant (dated May 25th, 1904).

Indian Medical Service.

The King has approved of the following promotions among officers of the Indian Medical Service made by the Government of India:—Captains to be Majors (dated Jan. 30th, 1904): *Bengal Establishment:* Bruce Gordon Seton. *Madras Establishment:* Robert Henry Elliot, Robert King Mitter, and Wilfred Ernest Arbuthnot Armstrong. Lieutenants to be Captains (dated Jan. 29th, 1904): Charles William Francis Melville, Robert McCarrison, James Masson, Norman Septimus Wells, William Morris Anderson, Edmund Hamilton Blake Stanley, William Hugh Leonard, Andrew Watson Cook Young, James Graham Goodenough Swan, Robert McLauchlan Dalziel, James Jackson Robb, Shaik Abdur Ruzzak, and Robert Basil Boothby Foster.

The King has also approved of the retirement from the service of the undermentioned officers: Colonel Christopher William Carr Calthrop (dated April 2nd, 1904) and Lieutenant-Colonel Thomas Henry Pope (dated March 1st, 1904).

Army Medical Reserve of Officers.

Surgeon-Major J. Adam to be Surgeon-Lieutenant-Colonel (dated May 3rd, 1904). Surgeon-Captain J. H. G. Whiteford to be Surgeon-Major (dated May 7th, 1904).

Volunteer Corps.

Rifle: 2nd Volunteer Battalion the Northumberland Fusiliers: Supernumerary Surgeon-Lieutenant (Honorary Lieutenant in the Army) J. Clay to be Surgeon-Captain (dated May 21st, 1904). 1st Volunteer Battalion, the Northamptonshire Regiment: William Peart Thomas to be Surgeon-Lieutenant (dated May 21st, 1904).

Royal Army Medical Corps (Volunteers).

The Manchester Companies: Lieutenant W. R. Matthews to be Captain (dated May 21st, 1904), and Harry Washington Pritchard to be Lieutenant (dated May 21st, 1904).

The Royal Military Tournament.

The Royal Military Tournament, now being held at the Agricultural Hall, Islington, N., has become one of the events of the London season and this year promises to eclipse all previous exhibitions excellent though they have been. The pageant represents the rise of the Royal Artillery from the days of the Black Prince to the present time, and for novelty there is "push-ball" with mounted players. A very satisfactory feature of the present tournament is the wider scope which has been allowed to the Navy to exhibit its wonderful agility and smartness, qualities which the public are never tired of witnessing. Surgeon-Lieutenant-Colonel W. R Crooke-Lawless of the Coldstream Guards is the Principal Medical Officer.

The War in the Far East.

Amid the various rumours and often conflicting statements that are being published in the press of this and other countries it is extremely difficult, if not altogether impossible, to form any adequate idea of what is actually taking place in the Far East We know little or nothing of the numerical strength of the Russian forces (except that they are big) or of what has become of the vast reinforcements alleged to have been sent east along the Siberian railway; and with regard to the strength and disposition of the Japanese forces in the field we can only form a very rough approximate estimate, while we know next to nothing of their strategical movements. The situation must always be read by the light of accomplished facts in the past and with the aid of maps and the exercise of a good deal of the "scientific imagination." The educated classes in Russia are said to have lost all faith in the official reports from the scene of war, but at the present time we are nevertheless learning more of the whereabouts of the Japanese from Kouropatkin than from Japanese sources. Whatever may have been the losses which the belligerent armies of both sides have suffered up to the present time, it is scarcely conceivable that these should not mount up to a grave total as the war goes on and the heat increases. We must remember possible outbreaks of epidemic sickness, the privations incident to warfare, and the neglect of hygienic precautions or, what amounts to the same thing, the impossibility of carrying them out under the conditions of such a war as that now going on. General Kuroki reports that the exact number of Japanese casualties in the battle of the Yalu was 318 killed, including five officers; and 783 wounded, including 33 officers. The Russian dead buried by the Japanese numbered 1363, whilst there are 613 prisoners. There does not seem to have been any fighting on a big scale since that on the Yalu and to be decisive in character in such a war as this big fighting must occur. Losses in affairs of outposts and reconnaissances are to be expected, but they only serve at best to indicate the preliminary movements of the belligerents and the possible site of a coming battle.

Information is forthcoming from the chief military medical committee that the organisation of measures to combat possible outbreaks of infectious diseases in the Russian army in the Far East is completed. Disinfecting chambers are already at the theatre of war and a large quantity of vaccine lymph has gone forward. Between the outbreak of war and May 1st there have been only three cases of small-pox at Chita, 14 at Verchneudinsk, and 15 at Ailanae. Orders have been issued that all spring waters used by the troops are to be carefully guarded, and if water must be taken from wells such water must first be tested by medical men.

On May 14th a gathering of medical men in St. Petersburg entertained and fêted Dr. M N. Chrabrostina and Dr. M. L. Banschikova of the ill-fated warships *Variag* and *Koreetz* respectively that were destroyed by the Japanese at Chemulpo. Accompanied with appropriate compliments they were presented with gold medals inscribed "To the honoured guest."

The *Novoe Dnya* of Kieff reports that of the 30 medical men of the reserve forces just called up in the Kieff military district 26 were Jews.

On May 14th, according to the *Novosti*, there were in the Red Cross hospitals in the Far East 6200 beds, whilst 2070 were on the way and 2700 were in preparation.

The *Novoe Vremya* reports an outbreak of fire at the headquarters of the Russian Red Cross Society in St. Petersburg on May 16th. The fire, which broke out at 7 P.M., was checked by the firemen on the third floor where it broke out.

A *Times* telegram states that Dr. Hashimoto, the Emperor of Japan's physician, Dr. Sato, and Dr. Kikuchi have been appointed superintendents respectively of the Tokio, Hiroshima, and Matsuyama military hospitals.

The Tibetan Mission.

In the *Times* of May 24th a special correspondent resumes his interesting description of the advance of the Tibetan Mission to Gyargtse and in doing so pays a tribute to the work of the Indian Medical Service. After the recent fight at the Hot Spring General Macdonald remained for three days at Thuna, says the writer, and then moved on to Guru, "passing over the scene of the sudden climax of the previous Thursday. There were, indeed, still some ugly traces of the tragedy, but everything that was possible had been done to restore the quiet shores of the Bam Tso to their usual quiet aspect, and it reflects no small credit upon the management of the Indian Medical Service that the wounded of the enemy were already so well cared for that numbers of wounded Tibetans had of their own motion applied for treatment by ourselves at Guru and the Hot Spring. Only the night before one or two had evidently been unable to drag themselves further and had fallen and died within a few hundred yards of our outposts. Many of the prisoners declined to accept their freedom and have remained at their own urgent request as coolies or dhooly-bearers in our service." Describing Kala Tso, which is the remnant of a vastly greater lake, the *Times* correspondent says: "The most remarkable thing was the evidence of a very large population in earlier days which the almost continuous string of ruined walls and villages supplied. For a space of nearly two miles the hillside of the road—which clings still to the mountains in avoidance of the now vanished lake—is marked by a wilderness of great round building pebbles dropped from the walls and houses of a lost civilisation, and still marked by lines of crumbling structure held together in the semblance of their first shape by dry layers of mud mortar. As with most things in Tibet, there are many reasons suggested for this wholesale desertion. Small-pox, the subsidence of the lake, the Mongol invasion, the ultimate inability of the inhabitants to adjust themselves to so wretched and inhospitable an environment, perhaps also the closing of the trade routes over the Sikkim passes—all may have had their effect."

THE AMIR OF AFGHANISTAN'S LATE INJURY.

The political value and importance attaching to the professional services which medical officers in India have from time to time rendered occupy a place in the past history of that country. The latest instance to be added to the record is that connected with the Amir of Afghanistan. His Highness wounded his left hand last month by the accidental explosion of a firearm and the injury was followed by the formation of an abscess, a process which was naturally attended with considerable pain. The Amir applied for the services of a European surgeon, whereupon Major R. Bird, the surgeon attached to the staff of the Viceroy of India, journeyed to Cabul and did all that was surgically speaking necessary for the rapid relief of the patient, who has expressed the greatest gratification for the services rendered.

THE PRIVATE FEES OF GOVERNMENT MEDICAL OFFICERS IN INDIA.

On page 1538 of our present issue our Special Correspondent in India gives the text of a notification of the Governor General in Council regarding the remuneration of medical officers for attendance on native chiefs, nobles, and native gentlemen of high position in a native State. The notification is one having an important bearing.

The latest report of the Sanitary Commissioner of India states that 29 per cent. of the mortality of the Indian European Army is due to enteric fever.

DEVON AND EXETER BENEVOLENT SOCIETY.—At the annual meeting of this society held at Plymouth on May 12th under the presidency of Dr. E. B. Thomson grants were made to four widows who applied for assistance. This society was founded in 1806 for the benefit of widows and orphans of medical men who have practised in the city of Devon and who have failed to leave adequate provision for their families upon their decease. The annual subscription is small and the benefits are great. Canvassing for votes is not necessary. All urgent cases are immediately relieved. At the next annual meeting such claims are considered and a yearly grant is made which is regulated according to the available funds of the society. There is a

give further information respecting the society upon request.

Correspondence.

"Audi alteram partem."

THE TENURE OF OFFICE OF THE MEDICAL OFFICER OF HEALTH.

To the Editors of THE LANCET.

SIRS,—The letters upon the above subject which have been appearing in recent issues of THE LANCET disclose conditions which ought not to be allowed to continue and I echo the sentiment of one correspondent in hoping that you will assist us in securing reform. As one of the honorary secretaries of the Incorporated Society of Medical Officers of Health I have perhaps exceptional opportunities for knowing how much the public generally suffer in some districts because the medical officer of health has to trim his reports to suit the whims of members of the council which elects him. The President of the Local Government Board is, I believe, in sympathy with us to a certain extent, but I cannot think he is altogether aware how much public health administration in small towns and rural districts is handicapped owing to the ease with which a medical officer of health who is not sufficiently complacent can at present be got rid of. If Mr. Long would institute a confidential inquiry among medical officers of health I am convinced that he would realise that some alteration ought to be made not solely in the interests of the medical officer of health but so that the Public Health Acts may be administered in a less lax manner than is the case now in many parts of England and Wales.

I am, Sirs, yours faithfully,

Hereford, May 24th, 1904. HERBERT JONES.

To the Editors of THE LANCET.

SIRS,—My own experience on this subject may be of interest to your readers. In March, 1901, I was appointed medical officer of health to a large combined district for a period of three years. The area comprises four urban and five rural districts. The appointment was a whole-time one but carried with it the post of medical superintendent to a joint hospital board. My predecessors have been appointed or reappointed for periods of either three or five years. About three weeks before the expiration of my term of office delegates from the various councils met to consider my reappointment. The delegate from *one* of the councils at once informed the committee that the council which he represented would refuse to remain in the combination should the reappointment be made for more than one year. No reason was assigned for this action. The other delegates thought it better to agree rather than run the risk of breaking up the combination. The Local Government Board professed to be unable or unwilling to interfere but expressed the hope that a longer term would be substituted at the next reappointment.

I am, Sirs, yours faithfully,

May 18th, 1904. X. Y. Z.

MEDICAL DEFENCE: A PARALLEL.

To the Editors of THE LANCET.

SIRS,—A parallel occurs to me:—

"A good deal has been said to-day about the man who is not a member of the British Medical Association. I venture to say I have no sympathy with him; he

of the British Medical Association.

Sec. Watch: How if a' will not

together, and thank God you rid of a knave.—*Much Ado ab Nothing*, act iii., scene iii.

I am, Sirs, yours faithfully,

May 23rd, 1904. F. BACON.

A WORD OF THANKS.

To the Editors of THE LANCET.

SIRS,—May I through the medium of THE LANCET thank all those who sent me votes for Mrs. Georgina Skinner for the Royal Masonic Benevolent Institution for the Widows of Freemasons and for their response to the appeal which was published in THE LANCET of April 30th? The election took place on Friday last and our candidate was successful with 3809 votes, being third of the 35 (from a list of 63 candidates) who were elected to receive the benefits of the institution.—I am, Sirs, yours faithfully,

HAROLD S. SINGTON,
Secretary, St. Luke's Medical Lodge of Instruction.
St. Mary's Mansions, W., May 23rd, 1904.

A SLIP.

To the Editors of THE LANCET.

SIRS,—I shall be much obliged if you will kindly insert the following statement in your next issue. In my address to the Royal College of Physicians on March 28th I inadvertently spoke of Dr. George Oliver, who has recently founded and endowed the Oliver-Sharpey lectureship at the Royal College of Physicians of London, as *formerly* of Harrogate, an expression which may, I am afraid, lead the Fellows of the College and others who may see my address to conclude that Dr. Oliver has left Harrogate. He informs me that he has no intention of leaving and that he will in the future, as during the last 15 years, reside and practise as a consulting physician in Harrogate during the summer months from June to October. Regretting the mistake I made and the annoyance I fear it has occasioned to our benefactor,

I am, Sirs, yours faithfully,
Belford, Northumberland, May 24th, 1904. W. S. CHURCH

SEPTIC CONJUNCTIVITIS.

To the Editors of THE LANCET.

SIRS,—In THE LANCET of Nov. 7th, 1903, you published some clinical notes I had made on a condition I described as "septic conjunctivitis." My attention has recently been drawn to an article by Parinaud on Infective Conjunctivitis and a review thereof in the May number of the *Ophthalmic Review*. The description given corresponds exactly with what I gave in my paper—constitutional disturbance, resemblance to trachoma, ptosis, non purulent discharge, affection of the preauricular glands, usually uniocular, therefore probably not very contagious, suggestion of animal infection, and slow complete recovery. No one reading the two accounts could doubt for a moment that the same condition was being described. The point to which I wish now to draw attention is that it is by no means so rare a condition as is suggested by the article in question which states that 20 cases only of this disease have been hitherto recorded, for even in my own practice I have had certainly over 20 cases. The explanation is that this disease is not, as I have before pointed out, differentiated in the English text-books on ophthalmology, so far as I have read, and I venture to suggest that those responsible for future editions would do well to give attention to this point.

I am, Sirs, yours faithfully,
Weymouth-street, W., May 24th, 1904. ROBERT W. DOYNE.

BURNING FROM THE X RAYS.

To the Editors of THE LANCET.

SIRS,—In the recent trial of the case of Smith *v.* Pare it was stated that the burns caused by the x rays are the most intractable known. In my experience at this hospital I have not found it so, although at first I certainly had some difficulty in curing them. But since I have used the following ointment I have found them amenable enough to treatment and the dermatitis soon disappears. Formula: Plumbi oxidum, one drachm; zinci carbonas, two drachms; glycerinum, one drachm; oleum olivæ, half a drachm; adeps benzoatus, to one ounce. The ointment to be applied freely.

I am, Sirs, yours faithfully,
H. LYLE,
Senior Surgeon to the Liverpool Hospital for Cancer and Skin Diseases.
May 24th, 1904.

THE OLD HARDSHIP OF LONDON MEDICAL STUDENTS.

To the Editors of THE LANCET.

SIRS,—In reply to your correspondent "Hard Lines" in THE LANCET of May 21st, I should like to point out that, though everyone will sympathise with him in his inability to pass all the final subjects at one time and more especially on account of the untoward circumstances which prevented him taking the examination at a time when he would perhaps have found it easier to do so, the position really only emphasises the greater amount of sound knowledge required for the degrees of those universities where the system of requiring all the final subjects to be passed at the same time obtains. It is comparatively easy to cram up one subject, to pass in that, and then while partially forgetting this to go on to another. It is surely most important that a man should be able to retain a good knowledge of all the final subjects and those who have shown themselves able to do so, whether from harder work, longer study, or greater ability, have a right to have the fact recognised to some extent

I am, Sirs, yours faithfully,
JUSTICE TO ALL.
May 23rd, 1904.

THE GERMAN CONGRESS OF INTERNAL MEDICINE.[1]

(FROM OUR BERLIN CORRESPONDENT.)

THE German Congress of Internal Medicine met this year at Leipsic from April 18th to 21st, Dr. MERKEL (Nuremberg) being in the chair. The official subject of discussion was

Arterio sclerosis.

Professor MARCHAND (Leipsic) said that arterio-sclerosis was a degenerative process, although inflammation or production of new tissue might sometimes happen. A distinction must be made between arterio-sclerosis, hypertrophy of the media, and syphilitic arteritis. Arterio-sclerosis was caused by functional hyper-exertion of the vessels and by accidental general or local causes, such as general impairment of nutrition, toxic and infectious processes, heredity, and influence of temperature. A certain form of sclerosis of the aorta, especially of the media and intima, was caused by syphilis and in some cases gumma might develop in the walls of the aorta; this form was termed meso-aortitis productiva (Chiari). Superficial atheromatous degeneration of the intima of the aorta in youthful individuals must be regarded as a symptom of the process. The degeneration of the elastic elements produced a more or less diffuse extension of the walls of the artery. Arterio-sclerosis was not seldom associated with hypertrophy of the left ventricle as a sequel to the general increase of resistance in the circulation. The process should be termed athero-sclerosis or sclero-atherosis of the arteries.

Professor ROMBERG (Marburg) said that the most important alteration of sclerosed arteries was the deficient elasticity which was somewhat overcome by aneurysmal dilatation of the lumen; the circulation was also hindered by the narrowing and lengthening of the sclerosed arteries. A slight hypertrophy of the left ventricle was somewhat rare and was present only in marked sclerosis of the aorta and the splanchnic arteries. With regard to the symptoms of arterio-sclerosis he said that sclerosis of the coronary arteries might produce angina pectoris and cardiac asthma; sometimes the disease showed only the uncharacteristic symptoms of chronic cardiac failure. The kidneys were sometimes affected with chronic interstitial inflammation complicated by insufficiency of the hypertrophied heart. The effects produced on the nervous system included neurasthenic troubles which occurred in the primary stage and might eventually lead to insanity. Diseases of the sensory organs and of the gastro-intestinal canal were rare. The resulting disorders of the nerves of the extremities and the general vaso motor neuroses were very interesting; intermittent claudication might be the first symptom of arterio-sclerotic gangrene. For the localisation of the disease in the different parts of the body the functional effects were important and not merely the anatomical lesions. Apart from general bodily over-fatigue substances which acted injuriously on the nervous system might cause the disease; over indulgence in tobacco, spirits, coffee, and tea was especially prejudicial because they produced considerable alterations in the tonicity of the blood vessels. Arterio-sclerosis was not due to senility but to exhaustion. Everything which tended to diminish the strength must therefore be avoided. Sufficient sleep and rest, with limitation of tobacco, spirits, coffee, and tea, should be recommended and residence in the country was desirable. Meat should be eaten sparingly. With regard to spa treatment, alkaline waters and those containing chloride of sodium were the most advisable. The administration of potassium iodide was excellent in the *early stages of the disease, in attacks of angina, and in* cardiac failure. It must, however, be remembered that the drug was unable to cure the anatomical lesions. It should be given in small doses for a somewhat long time. There were no other medicines of much use in arterio-sclerosis. Nitrites and nitro glycerine only relieved symptoms. Digitalis and strophanthus might be given but in small doses only. Bathing in water charged with carbonic acid gas was beneficial in the beginning of cardiac insufficiency or in partial recovery after serious attacks. Gymnastic methods of strengthening the heart were useful only during convalescence or in the case of corpulent patients.

---

[1] For this report we wish to tender our thanks to the editor of the *Deutsche Medicinische Wochenschrift*, through whose courtesy it has been forwarded to us by our correspondent.

Professor KLEMPERER (Berlin) directed attention to the fact that arterio-sclerosis was prevalent in the medical profession because the work of the medical man often prevented him from having sufficient rest and regular meal times.

Professor VON NOORDEN (Frankfort) recommended a 5 per cent. alcoholic solution of nitro-glycerine in cases of arterio-sclerosis with high blood pressure. He saw sometimes the pressure decrease from 200 to 120 millimetres of mercury, the effect lasting for from eight to 14 days. The recommendation made by Dr. Rumpf—namely, the exclusion of calcium salts from the food—was in his opinion unsound when regarded from a therapeutic point of view and hardly possible to carry out in practice.

Dr. SCHOTT (Nauheim) insisted on the coincidence of arterio-sclerosis and insufficiency of the aortic valves. Tobacco, wine, and strong beer were, he said, the principal causes of the disease. He was opposed to the dietetic prescriptions of Dr. Rumpf because they often produced neurasthenia. Temperate habits and a mixed diet of good quality were the best therapeutic agents. Carbonic acid

never injurious. A 1 per

sometimes beneficial.

xpressed the opinion that neurasthenia was not so often a cause of the disease as was believed by Professor Romberg. Neurasthenia was, on the other hand, the first symptom of arterio-sclerosis. Spirit-drinking must be avoided entirely but tobacco-smoking in moderation might be allowed. *Iodine might be prescribed* but digitalis would better be avoided.

Professor FRAENKEL (Berlin) discussed the influence of infectious diseases and especially of their toxins on the genesis of arterio-sclerosis. The thrombosis which occurred in the course of infectious diseases might be a symptom of toxic alterations of the walls of the blood-vessels. He had never observed arterio-sclerosis in children. Referring to the "dysbasia angio sclerotica," described by Professor Erb, he directed attention to the so-called "dysphagia angio-sclerotica" which was characterised by meteorism, severe pains in the abdomen, giddiness, and fœtid stools. In asthma a combination of digitalis and morphine was recommended.

Professor SATTLER (Leipsic) spoke of the localisation of arterio-sclerosis in the retinal arteries. In grave cases hæmorrhages and emboli of the central artery were frequently present.

Dr. ERB, jun. (Heidelberg), said that Dr. Nissel and himself had made experiments on the artificial production of arterio-sclerosis by injections of adrenalin. He found, as had been stated by French authors, that after a few injections white spots in the walls of the vessels, small aneurysms, and real atheromatous ulcers were produced. On microscopical examination hyperplasia of the endothelium, formation of cartilaginous tissue, and rupture of the elastic fibres were found.

Dr. BAHRDT (Leipsic) reported that in a Leipsic life insurance company during the past 11 years the mortality from arterio-sclerosis and its sequelæ (apoplexy, gangrene, &c.) was 22 per cent. of the insured in general, the mortality from tuberculosis being only 7 per cent.; the latter disease was steadily decreasing whilst arterio-sclerosis had a tendency to increase.

Dr. HOPPE SEYLER (Kiel) read a paper on the pathological conditions of the pancreas in arterio sclerosis. He said that the acini of the gland became atrophied by hyperplasia of the connective tissue.

Dr. GRODEL (Nauheim) read a paper on the value of determinations of the blood pressure in the treatment of arterio-sclerosis. In 500 cases of well marked arterio-sclerosis he found that in 35 per cent. there was no increase of the blood pressure and that in 18 per cent. the pressure was very slightly increased. In the cardiac insufficiency of persons suffering from arterio-sclerosis when the blood pressure was normal digitalis and carbonic acid baths might be administered just as to other patients suffering from cardiac diseases. When the blood pressure was increased small doses of digitalis might be given for a somewhat long period. The carbonic acid baths, though not of the same advantage as in cases of normal blood pressure, were nevertheless useful; they must, however, be of short duration. It was only in cases where the cardiac insufficiency was very great and a tendency to apoplexy and embolism was present that they were absolutely contra-indicated.

(To be continued.)

CHOLERA IN MESOPOTAMIA AND PERSIA.

(FROM THE BRITISH DELEGATE TO THE OTTOMAN BOARD OF HEALTH.)

IT is a matter for sincere congratulation that there has been so far no revival in the present year of the outbreak of cholera which was the cause last year of so many deaths in the Syrian and Aleppo vilayets of the Turkish empire. Rumours have been current from time to time of the reappearance, or of the continued existence, of the disease in Aleppo and elsewhere but they have never been substantiated. In Mesopotamia, on the other hand, and in the adjoining portions of Persia there can be no doubt that an epidemic of considerable, though by no means alarming, proportions is in progress.

Since the date of my last letter[1] there has been no diminution of the disease in Basra, while it has made its appearance in several places on the Tigris and Euphrates and has slightly extended its area of prevalence in Persia. In Bagdad there has been no known case of cholera since April 6th and it is believed that the outbreak is truly at an end there. The river quarantine at Garara and the land quarantines imposed by the local authorities at Khan-beni-Said, at Mahmudie, and at Feloudja have been suppressed.

The following statistics for Basra are in continuation of the table in my last letter:—

From April 11th to April 14th ...	13 cases	17 deaths.
„ „ 15th „ „ 23rd ...	34 „	31 „
„ „ 24th „ „ 26th ...	18 „	17 „
„ „ 27th „ May 5th ...	37 „	35 „
On May 6th	7 „	4 „
„ „ 7th	3 „	2 „
„ „ 8th	9 „	9 „
„ „ 9th	11 „	4 „
„ „ 10th	8 „	2 „

The total number of known deaths in one month was consequently 121. The difficulty met with by the local authorities in obtaining knowledge of all the cases which occur is shown by the fact that of this total of 121 deaths no less than 69 only became known to them after death had occurred.

Cholera appeared at Samawa, on the Euphrates (south of Kerbela), on or about April 17th. Between that date and the 23rd 11 cases and eight deaths were reported to have occurred there. No fresh news was received thence until the 29th, when 1 case and 5 deaths were reported; on the 30th there were 4 cases and no deaths; on May 1st 4 cases and 1 death; from May 2nd to 4th one case and three deaths; and from the 5th to the 8th seven cases and ten deaths. The outbreak is apparently increasing rather than decreasing at Samawa. On April 29th the disease appeared at Nasrieh, a place on the Euphrates about half way between Samawa and the junction of the river with the Tigris. Up to May 7th there had been 17 cases and ten deaths there. On May 10th an imported case occurred at Gourna (? Korna, at the junction of the two rivers) in the person of a marine who had come from Basra and died after 14 hours' illness.

Cholera has also been reported from Djivarir, Hamar, and Remineh, places which are not marked on the maps at my disposal but which are certainly in the neighbourhood of the places already mentioned. At Djivarir (also called Ivdjivar) 14 cases and eight deaths occurred between April 28th and May 1st. At Hamar four cases and five deaths were reported between April 30th and May 1st; and at Remineh 11 cases and three deaths on May 2nd and 3rd.

---

[1] THE LANCET, April 23rd, p. 1153.

Unfortunately little is known of the course of the disease on the Persian side of the Turco-Persian frontier. All that is known so far is that it appeared at Kermanshah in the first week of April, that six cases and four deaths had occurred there before the 9th of that month, that one more death was recorded in the week ending on April 19th, and that on the 20th five cases and four deaths were reported. No later news has been received from the sanitary officer there, but on May 2nd the Turkish Consul telegraphed that no further cases had been observed at Kermanshah, but that at Kenadir 19 cases and nine deaths had occurred. The last named place is difficult to identify. Possibly it is the same as Kengover where it was reported on April 26th that up to that date 28 cases and 16 deaths had occurred in the preceding 18 days. At another obscure place called Heyaver in the telegrams five cases with five deaths were said to have occurred on April 20th. It is obvious from these irregular and scanty sources of information that cholera is slowly extending its area of prevalence in Persia, though, as already stated, it has not as yet assumed the proportions of an alarming epidemic.

Constantinople, May 14th.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

Medical Officers and Native Chiefs: Government Order.—The Plague Epidemic.—A New Disinfectant for Plague.—The Accident to the Amir of Afghanistan.

THE following notification is published by the Home Department:—"The Governor-General in Council is pleased to direct that the following shall be substituted for paragraphs 3 and 4 of the Home Department Notification No. 437, dated July 25th, 1893, amended by the Home Department Notifications of 1900 and 1901, regarding the remuneration of medical officers for attendance on native chiefs and nobles and native gentlemen of high position in a Native State. The native chief or gentleman may offer any medical officer of the Government attending him such fee as he thinks fit to make and it will be reported by the medical officer to the political agent or other officer of the Government exercising political functions in the State of which the said chief, noble, or gentleman is a resident for the consideration of the local government within whose jurisdiction the native state is situated. This report will state the period during which he was in attendance and the number of visits paid. The medical officer will at the same time submit to the administrative medical officer or inspector general of hospitals to whom he is subordinate a full medical statement of the case showing the nature and extent of the relief afforded, the importance of the case from a professional point of view, and the circumstances in which he attended the patient. The local government is required to satisfy itself that the fee proposed is not out of proportion to the relief afforded and to the circumstances of the case and has authority to sanction the acceptance of a fee not exceeding Rs.2000. In considering these questions it will if necessary refer to the administrative medical officer or inspector-general of civil hospitals as the case may be. If the proposed fee exceeds this sum the matter will be submitted with a full report by the local government for consideration and orders of the Government. The reports prescribed in the preceding paragraph will not be required from a medical officer when the fee does not exceed Rs.50 a visit or Rs 1000 in the aggregate for repeated visits in the course of a year." It is difficult to see what reasons have determined the Government to exercise this interference with the private practice of civil surgeons. The new order reflects severely upon medical officers of the Government, and no reasons are given for it. It will lower the estimation in which the Indian Medical Service has hitherto been held by the natives of India. The following quotation from an important native paper in Calcutta gives some idea of the views of the natives on this new order. "The recent regulations regarding fees charged by medical officers for attendance upon native chiefs possibly contain more than meets the eye. It is difficult to conceive of the necessity for promulgating such restrictions unless on the assumption that some residency surgeons had taken advantage of their position to charge exorbitant fees for attendance or to take to intriguing under cover of professional visits. In some native States the residency surgeon exercises an influence which is not wholly traceable to his professional skill and we therefore welcome the new regulations which are designed to impose a limit upon the self-seeking of those sons of Æsculapius who are either too extortionate or too intriguing." The base insinuations conveyed in these paragraphs can be ignored but they express an animus against British officials which has been shown far too commonly of late. The profession will undoubtedly regard this new order as the essence of grandmotherly fussiness and when the absurdly small limits for fees are considered there seems to be ample justification for this opinion.

The plague returns for the week ending April 23rd show a satisfactory fall of about 8000 in the plague mortality throughout India. The figures are still very high, the total deaths for last week being 38,748. The principal returns are: Punjab, 24,714 deaths, as against 26,961 for the previous seven days; United Provinces 4279, as against 6197; Bombay *Districts 3723,* as against *5128; Bengal 1439, as against* 1942; Rajputana 1072, as against 1055; Central Provinces 498, as against 704; Central India 732, as against 1288; Bombay city 563, as against 706; Calcutta 440, as against 500; and Karachi 249, as against 294. Kashmir reports 578 deaths. Later reports show that the disease is rapidly declining in Calcutta and Bombay city.

A new form of disinfectant has lately been advocated for plague in a liquid hydrocarbon obtained as a by-product in the manufacture of gas. It can only be used on buildings not easily set on fire. It is a yellow oily-looking fluid, highly combustible, and volatile. In using it all apertures are first closed, then the fluid is sprinkled on the floor and ignited. It blazes up furiously and gives off a thick black smoke. Its virtue is said to be in its destructive power against vermin and obnoxious insects. Rats quit the building and if they cannot escape they die asphyxiated. The great danger attending its use will obviously prohibit its general employment.

For the recent accident to the Amir of Afghanistan the services of the Government surgeon were asked for and Major R. Bird, I.M.S., has proceeded to Cabul. It appears that the Amir had one finger of the left hand severely lacerated by the bursting of his gun. This was the main reason for his asking for surgical assistance from India as the other injuries to his hand were comparatively slight.

May 5th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Hospital Saturday Fund.

THE twenty-fourth annual collection in warehouses, workshops, and other industrial establishments on behalf of the medical charities of the city took place on May 14th. The boxes have not all been sent in yet to the treasurer of the fund, but the amounts received to date (£4416) represent an increase of £800 on the receipts of the same week in last year. Through the agency of the Hospital Saturday Fund the local charities have benefited to the extent of £123,750 during the last 23 years. This sum falls far short of supplying the growing demands of the hospitals and the hope of the committee lies in enlisting widespread sympathy and active coöperation, particularly in organising in each place of employment a regular system of weekly contributions of pence and halfpence. This system has been attended with the most satisfactory results where it has been adopted.

A New Honorary Appointment at the Royal Infirmary.

The committee of the Royal Infirmary has adopted a resolution recommending the appointment of an honorary assistant gynæcologist to the Thornton wards. The post has become a necessity owing to the growth of work in the out-patient department. The election will be made on the same lines as in the other honorary appointments and will be in the hands of the election committee.

The New Chair of Physical Chemistry at the University of Liverpool.

Mr. F. G. Donnan, Ph.D., M.A. Dub., has been appointed to the new chair of physical chemistry at the University of Liverpool.

Health of Liverpool.

During the week ended May 14th 241 deaths were registered, being equivalent to an annual mortality of 17·3 per 1000. There were 472 cases in the city hospitals, including three of small-pox, 315 of scarlet fever, 29 of typhoid fever, 16 of measles, and 49 of diphtheria. In the Brownlow Hill Workhouse Hospital there were 1391 patients.

May 24th.

WALES AND WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENTS.)

Sanitary Inspection in Rural Districts.

Mr. Wyndham Randall, the medical officer of health of the rural district of Penybont in Glamorganshire, has upon several occasions drawn attention to the need of more systematic sanitary inspection in his district. At the end of last year an inquiry was made for the Local Government [illegible] each to be in the charge of an [illegible] as surveyor. The area of the [illegible] acres and the population is over 1[illegible] decided on May 7th to carry out the proposal of the Board, one member only, a clergyman, expressing the opinion that it was not desirable to appoint another inspector. Hitherto the Local Government Board has opposed the combination of the offices of nuisance inspector and surveyor even in country districts where the duties of the latter officer are often merely those of a road foreman, so that the course taken in connexion with the Penybont district may be a precedent to be followed in other districts.

Failure of Proceedings against a Butcher.

A carcass of meat alleged to be tuberculous was recently seized in Cardiff and proceedings were taken against a butcher for exposing the meat for sale. The stipendiary magistrate dismissed the case because he was not satisfied that there was anything more than technical "exposure for sale." It is now reported that the butcher is claiming damages against the corporation under Section 308 of the Public Health Act, 1875. In the event of arbitration following the result will be of interest if only because a different decision has been arrived at in each of the principal cases which have hitherto been the subject of similar proceedings—those at Birkenhead, Brighouse, and Rhondda.

Winsley Sanatorium.

A meeting of the West of England and South Wales branch of the Incorporated Society of Medical Officers of Health, under the presidency of Mr. J. Tubb-Thomas, medical officer of health of the county of Wiltshire, was held on May 19th at the Winsley Sanatorium near Bath. Dr. L. A. Weatherley described the buildings which contain accommodation for 60 patients. The site of the institution is 600 feet above sea level and commands a magnificent view over Salisbury plain with the Westbury white horse clearly visible 15 miles distant. The buildings are constructed of Bath stone quarried from the estate. Each patient is to have a separate bedroom, which is heated with hot-water pipes on the low-pressure system. The aim of the designers to avoid all angles and ledges has been very well carried out and the sloping of the window-sills and bevelling of the sides of the windows are distinct features in all the rooms. Where so much care has been exercised in connexion with details it is disappointing to find that no cross ventilation has been provided for the water-closets and lavatories; even in modern hotels this very necessary precaution is taken. The cost of the buildings is not by any means excessive; it works out at a little over 6*d.* per cubic foot.

Scarlet Fever Isolation in Cardiff.

At the same meeting Dr. Edward Walford contributed to the discussion which is now going on with regard to the desirability of isolating cases of scarlet fever. He gave the experience of Cardiff and contended that if the question was to be considered from a statistical standpoint it would be safer to rely upon the statistics of one town, comparing the results in that town at different periods according to the amount of hospital isolation carried out. As illustrating the fallacy of comparing one town with another he cited the experience of Swansea, which town has been held up as an instance where very little scarlet fever accompanied little or no isolation and he compared it with the Rhondda urban district where there was also no isolation but where there was an attack rate of 8·7 per 1000 in the five years 1897–1901 and of 16 3 per 1000 and 12·1 per 1000 in 1900 and 1901 respectively. The experience of Cardiff during three epidemics showed that in 1884, when there were no patients isolated, the attack rate was 28 per 1000; in 1892 there were isolated 13 per cent. of the cases and the attack rate fell to 13 per 1000; while in 1902, with 48 per cent. isolated, there was a still further fall in the attack rate to 8 per 1000. The same diminution in the death-rate from the disease occurred in the three periods specified—namely, 1·36 per 1000, 0·65 per 1000, and 0·21 per 1000 respectively. Dr. Walford deprecated the aggregation of acute and convalescent cases in the same ward and for the latter he advocated the provision of separate wards.

"Westrumite" in Swansea.

Swansea is the first place in South Wales where "westrumite" has been used for laying the dust upon roadways. The portion of the Mumbles road which was selected for treatment has been noticeably free from dust and when a motor-car passes along the road the portion untreated can be only too readily distinguished.

Small-pox.

There is one case of small-pox in the Barry Hospital and there are four cases in the Cardiff Hospital from two houses. The last patient to be attacked in Cardiff was infected from a house in which there were four unrecognised cases. The youngest patient from this house was an unvaccinated baby who died in the hospital.

Diphtheria in Bristol.

A systematic search for "carrier" cases is now a part of the routine work of the Bristol health department whenever a particular district of the city is threatened with diphtheria. But as the medical officer of health (Dr. D. S. Davies) has pointed out, the first effect of the house to-house visitation is apparently to magnify the extent of the epidemic, for cases come to his knowledge which he would not otherwise hear of; the ultimate result, however, is a considerable shortening of the epidemic. An outbreak of the disease occurred in Fishponds early in May and 20 unsuspected cases which would probably have been "carriers" followed the investigations made by Mr. J. C. Heaven, the deputy medical officer of health. Some of the local practitioners and others advocate the closing of the schools attended by the children affected, but Dr. Davies's method is distinctly more scientific and he declares it to be more effectual.

Memorial to the late Mr. Joseph Harper of Barnstaple.

The Bishop of Crediton on May 16th dedicated a new choir vestry at St Mary Magdalene's Church, Barnstaple, which has been erected by public subscriptions as a memorial to the late Mr Joseph Harper, L.R C.P. Lond., M R C S. Eng., who for 16 years served as churchwarden.

May 23rd.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

The University of Glasgow and the Thomson Bequest.

AN interesting ceremony took place in the anatomical department of the University of Glasgow during the afternoon of May 18th when a tablet in brass repoussé work was unveiled in commemoration of the grant made by the trustees of the J. B. Thomson bequest which had enabled the University Court to build and to equip the new anatomical department. [illegible] ledged the [illegible] the Thomson [illegible] enabled the [illegible] way an impo[illegible]

[illegible] Bellefield Sanatorium, Lanark.

It has now been definitely arranged that the new sanatorium erected in the Bellefield estate near Lanark by the

Glasgow and District branch of the National Association for the Prevention of Consumption and other Forms of Tuberculosis will be formally opened on June 7th. A special train will convey the guests to Cleghorn from which station they will drive to Bellefield. At the conclusion of the opening ceremony a reception will be held, after which the company will have an opportunity of inspecting the grounds and buildings of the sanatorium.

British Medical Association: Annual Dinner of the Glasgow Branch.

The annual dinner of the Glasgow and West of Scotland branch of the British Medical Association was held on the evening of May 20th in St Enoch's Station Hotel, under the presidency of Dr. J C. McVail, the guest of the evening being Mr. Andrew Clark, F.R.C S. Eng., chairman of the Council of the Association. In replying to the toast of "The British Medical Association," proposed by Dr. Ebenezer Duncan, Mr. Clark pointed out that when the Association was founded in 1832, under the name of "The Provincial Medical Association," there were only 50 members on the roll. Now the membership numbered 19,000. There were 37 branches in the United Kingdom and 26 in the colonies and he believed that before long they would have branches in the Orange River State and in the Transvaal. Dr. D C. McVail, in replying to the toast "Other Scottish Branches," proposed by Professor McCall Anderson, referred to the prevalence of quackery and stated that last year the Government pocketed £330,000 for "quack" medicine stamps and that next year the sum would be greatly increased on account of many wholesale makers of medicines being compelled to put stamps on preparations hitherto unstamped. This was a serious question and indicative of the condition of the public mind who were nevertheless kept in ignorance of the progress of medicine and surgery. With the exceptions of the meetings of the British Medical Association medical bodies did not permit reports of their doings to be inserted in the daily press How, therefore, could the public be educated and how were they to know the difference between true medicine and quackery? That was a question for the Association to consider.

Opening of Kingseat Asylum.

Kingseat Asylum, Aberdeen, having been duly licensed by the General Board of Lunacy for the accommodation of patients, was formally declared open on May 14th. Mr. George Murray, chairman of the Aberdeen City District Lunacy Board, performed the ceremony at the close of an inspection of the buildings by the asylum committee of the board. Mr. Murray, in declaring the institution open, said that the cost of the new asylum had frequently been commented upon but it had to be borne in mind that whether the Royal Asylum directors, or the Lunacy Board, or the parish council had to provide accommodation for lunatics the cost had to be met and money had to be expended. The Lunacy Board had decided wisely in advising the construction of an asylum on the newest principles and on the most approved methods, the number of patients being limited to 500 or 700 From Mr. Spence, the secretary of the General Board of Lunacy for Scotland, the following congratulatory letter had been received:—

> I am directed by the board to inform you that on the 11th inst. they made [illegible] the asylum at Kingseat and found that the [illegible] that they were of substantial and econ[illegible] re admirably adapted to their purpose, that they were provided with suitable and comfortable furniture, that the arrangements for heating, lighting, and generally for carrying on the work of the asylum were efficient, that the arrangements for a water-supply, for the extinction of fire, and for the disposal of sewage were satisfactory, and that the asylum was provided with a suitable and adequate staff. The board accordingly resolved at a meeting subsequently held to approve of and adopt the asylum as a district asylum for the Aberdeen city lunacy district.

On May 16th 50 male and 50 female patients were despatched to Kingseat from Aberdeen Royal Lunatic Asylum, 32 male and 34 female patients from the West Poorhouse, and 45 male and 50 female patients from the East Poorhouse.

The late Mr. William Heathe Ferrier.

Mr. William H. Ferrier of Kyle, Ross shire, whose death from a very acute illness is announced, commenced medical study somewhat later in life than is customary, having previously been for ten years engaged in the scholastic profession. It is stated that he was at one time offered, but did not accept, an appointment as private secretary to a nobleman well known as a colonial governor. Mr. Ferrier's medical education was partly received in Glasgow, and in 1895 he became qualified as L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg. He has left a widow and one child.

May 24th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Sir Charles Ball, M.D. Dub., F.R.C.S. Irel.

THE King has been pleased to appoint Sir Charles Bent Ball, Regius professor of surgery, University of Dublin, to be one of His Majesty's honorary surgeons in Ireland in the room of Sir Philip Crampton Smyly, deceased.

The Poor-law Dispensary System in Ireland

The annual general meeting of the Leinster branch of the British Medical Association was held in the Royal College of Physicians of Ireland, Kildare-street, Dublin, on May 19th, when the outgoing president, Dr. J. Magee Finny, delivered an address dealing with the Poor-law dispensary system. He referred to the short-sighted political economy which induced the conclusion of the Local Government Board that the greater the reduction in the population the fewer should be the number of the medical officers. As to the necessity for some form of promotion within the service, he said that two forms appeared to be feasible and desirable, first the natural movement from less lucrative districts to those with richer populations or easier work, and, secondly, a movement from executive to administrative positions. But he entirely disagreed with the idea of making the Poor-law medical service practically a Government department as had been suggested. He was of opinion that the highest administrative posts in the service should be open to the Poor-law officers of Ireland and to a larger extent than at present, and that the system of inspectors of the Local Government Board as now existing is not the best for the service or for the country.

Irish Medical Association.

The annual meeting of the Belfast and District branch of the Irish Medical Association was held in the Medical Institute, Belfast, on May 20th. After the transaction of the ordinary business the following were elected office-bearers for the year 1904-5:—President: Professor J. W. Byers Vice Presidents: Mr. S. B. Coates and Mr. H C. Manley. Secretary and treasurer: Dr. A. G. Robb. Council: Mr. H. D. Osborne, Mr. R Hall, Dr. J. St. C. Boyd, Dr. J. C. Ferguson, Dr. R J. Munn, Dr. W. R. Davison, Dr. A. Mussen, Dr. D. P. Gaussen, and Mr. J. G. Jefferson.

Monaghan and Cavan Asylum.

At a meeting of the Monaghan and Cavan Asylum board on May 19th the resident medical superintendent (Mr. E. Taylor) submitted the thirty-fifth annual report. 1001 patients had been under treatment during the year 1903 82 had been discharged, 61 died (7 1 per cent. of the average number in residence), and there was a high percentage of 34 caused by pulmonary tuberculosis. At the close of the year there were ten patients less than at the beginning. The expenditure had been £22,213 16*s*. (£19,203 12*s*. 10*d*. for maintenance and £3010 3*s*. 2*d*. in repayment of loans). The net cost per head for maintenance had been £21, which was £1 7*s*. 11*d*. less than for the previous year.

May 24th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Nascent State and the Properties of Drugs.

AT the meeting of the Academy of Medicine held on May 9th M. Albert Robin read a most interesting paper. He stated that the therapeutical action of certain synthetic remedies and the special properties of chemical bodies when set free by contact with the tissues are greatly exalted, as indeed are those of all bodies in the nascent state. Solution of hydrogen peroxide is a typical example and has a marked action by means of the oxygen which it gives off. Willstätter has stated that solution of hydrogen peroxide acts like water of crystallisation and forms combinations which will break up into oxygen on the one hand and the crystalline body on the other. Thus it is possible to combine with acetate of sodium 23 parts per 100 of its weight of oxygen, and even alum will combine with solution of hydrogen peroxide. The peroxides are specially interesting as regards the subject of the paper; for instance, the peroxides of calcium or of magnesium set their oxygen free on coming into contact with the gastric juice, or if administered in a keratin capsule the decomposition will be delayed until the intestine is reached. The antiseptic action on the intestinal contents is very marked, especially upon fermentation, and in this way the drug is useful in certain forms of diarrhœa. Unna has employed sodium peroxide in affections of the skin in the form of an ointment of from 3 to 5 per cent. strength. Peroxide of zinc acts in the same way, the action of the nascent oxygen and the nascent zinc being mutually increased. Of other combinations, hypnol or mono-chloral antipyrin containing 45 per cent. of chloral and 55 per cent. of antipyrin acts well in doses of one gramme. Aspirin or aceto acetyl salicylic acid has an analgesic effect much more powerful than either of its two constituents. Quinofortine or quinate of urotropine and sudoral or quinate of piperazine act, on the one hand, by giving up benzoic acid which is changed into hippurate and, on the other, urate of piperazine which is formed in the body and is extremely soluble. These drugs when given so as to be absorbed in the nascent state act very well and it is quite unnecessary to give big doses as is the custom in Germany; small quantities are quite sufficient. Iodide of sulphur has an analogous action. M. Prunier has shown that sulphur and iodide will combine according to the formula $S_{18}I$ and that this drug when administered sets free its iodine by contact with the gastric juice so slowly that no toxic effects are produced. It may be given so as to act in the intestines by being admininistered in keratin capsules. Very small doses, such as from 10 to 30 centigrammes, will lessen gastric fermentation and fœtor of the breath. The acids due to fermentation are markedly reduced Iodide of sulphur acts well in gaseous fermentation but not in cases of butyric fermentation, while in surgery it is useful in the treatment of ulcers of the leg. The double iodide of bismuth and cinchonidine, known under the name of "erythrol," if applied to a wound decomposes into iodine and cinchonidine. It is an admirable disinfectant of putrid wounds, especially such as are cancerous, or in cases of wounds of the mouth. Again, by combining alkaloids such as morphine or cinchonidine with various substances different medicaments may be obtained suitable for varying conditions which will act excellently well owing to the nascent state in which their constituents are given off when they are decomposed.

Occupation Neuritis in a Coachman.

At the meeting of the Neurological Society held on May 5th M. Raymond and M. Courtellemont showed a patient suffering from Polyneuritis of both Hands and Synovitis of the Wrist-joints. There were present among [illegible] ypo-æsthesia, [illegible] were painful [illegible] owing to his occupation as coachman to keep the reins tightly stretched for many hours a day and the paralysis was due to fatigue. The injury was caused in two ways—one by pressure on the nerves from the muscles of the hand and forearm and two by compression of the nerve twigs by the synovitis. M. Raymond and M. Courtellemont concluded their demonstration by pointing out that the signs in this case enabled a diagnosis to be made between a true acroparæsthesia and the symptomatic or false acroparæsthesia which is so often present in cases of peripheral neuritis.

Medical Cases in the Law Courts.

Three cases of medical interest have recently been decided by the courts. The first case which came before the Third Chamber of the Civil Tribunal was shortly as follows. The Baroness de H. engaged Dr. N. as body physician in June, 1902 An agreement was signed for one year, Dr. N. receiving 750 francs per mensem, exclusive of board, lodging, and incidental expenses. After seven months had expired the baroness suddenly dismissed Dr. N. in Paris, through which town she happened to be passing. Dr. N., therefore, promptly summoned the baroness before the court for breach of contract and for summary dismissal, claiming damages to the amount of 5130 francs. The court reduced the damages to 1748 francs, holding that the baroness had a right to dismiss Dr. N. even according to the contract but that the summary manner in which she had chosen to dismiss him was prejudicial to his career as a medical man. The second case which came before the Tenth Chamber was concerned with a medical man who was helped in his consultations by a somnambulist. The point was whether both he and the somnambulist were guilty of the illegal practice of medicine. The Syndicate of Medical Men of the Seine decided that both were guilty and prosecuted Dr. L. and the somnambulist. The court, however, took a different view. Dr. L., they argued, was properly qualified and as he alone was consulted he had committed no offence. But Madame E., the somnambulist, had no right to prescribe and had thus committed an offence. The question then came up, as the [illegible] were they both innocent or both [illegible] came to see Dr. L. he put the [illegible] she dictated a prescription which Dr. L. read over and signed. The patient then took the prescription to the dispensing druggist in the usual way. The accused were fined 200 francs respectively and the court in addition allowed the Syndicate of Medical Men of the Seine 200 francs costs. In the third case a medical man sued a patient for the amount of his bill. The patient replied that on account of the bill having run for two years the debt was statute barred. The court, however, decided that each visit constituted a separate debt and that although some of the visits were statute barred yet some were not. The patient, therefore, was ordered to pay what he owed for such of the visits as were within the period of two years.

May 22nd.

THE GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

THE seventy-ninth session of the General Medical Council was opened on Wednesday, May 25th.

The regular day for the summer meeting of the Council is the fourth Tuesday in May but owing to the fact that this year that day directly followed Whitsun Monday the opening of the meeting was postponed until the Wednesday.

The changes in the *personnel* of the Council are due to the retirement of Mr. Bryant and to the appearance for the first time of a representative of the University of Liverpool. Mr. Bryant is succeeded by Mr. Henry Morris as the representative of the Royal College of Surgeons of England, and Dr. Richard Caton of Liverpool is the representative of the University of that city.

Mr. Bryant's period of office as representative of the Royal College of Surgeons of England upon the Council expired last March and he decided not to seek re-election. For many years Mr. Bryant has been one of the most persistent workers on the Council. He has been joint-treasurer, chairman of the Examination Committee, and member of the Executive Committee, and in the discharge of the duties involved he has displayed administrative energy and an unfailing genial courtesy. The medical profession will be glad to learn that Mr. Bryant's connexion with the Council has not quite ceased as he has consented to act as inspector of examinations for the Council during the present year. On personal and on professional grounds, as well as because of his close familiarity with the subject, Mr. Bryant, who will be accompanied by a Fellow of the Royal College of Physicians of London as a visitor, will fill the post admirably and we confess that we are a little astonished to find Sir Victor Horsley objecting to his appointment as he is understood to have done.

WEDNESDAY, MAY 25TH.

The seventy-ninth session of the General Council of Medical Education and Registration opened in the Council

Chambers, 299, Oxford-street, London, W., to-day, Sir WILLIAM TURNER, the President, being in the chair.

An Absent Member.

While the roll was being called the PRESIDENT said he was sorry to intimate that he had had a letter from Mr. Tomes who was so ill that he was not able to attend the meeting of the Council. He thought that they should express their regret.

This was agreed to.

New Members.

Official notification was made of the appointment of Mr. Henry Morris and Dr. Richard Caton as members of the Council, the former by the Royal College of Surgeons of England, in place of Mr. Bryant, retired, and the latter by the council of the University of Liverpool. Mr. Morris was introduced by Dr. Norman Moore and Dr. Caton by Mr. Young.

The President's Address.

[The PRESIDENT commenced his address by welcoming Mr. Morris and Dr. Caton to the Council and by expressing his warm appreciation of the work done by the retiring member, Mr. Bryant, as one of the treasurers, as chairman of the Examination Committee, and as a member of the Executive Committee. He also announced that Mr. Bryant had most kindly consented to undertake the duties during the present year as inspector of examinations in the place of the late Sir George Duffey. He continued :]

At the meeting of the Council on Nov. 27th a committee was appointed to consider the report of the Examination Committee on the questions raised in the reports of the inspector and visitor of the preliminary scientific examinations of the three Conjoint Boards and the Apothecaries' Society of London. Before the termination of that session the committee adjusted the terms of a letter which I addressed to all the licensing bodies in the United Kingdom and to the scientific teaching institutions recognised by them and approved by the Council. During the winter replies were received from the great majority of the bodies and institutions. These replies were summarised in the office by the Registrar, assisted by two of the clerks, and a proof in type was submitted to me early in April. It was obvious, if a report were to be drawn up by the committee, circulated amongst members of Council, and properly considered during the present session, that it would be necessary to call the committee together before the meeting of the Council and to frame a report in which should be embodied the recommendations to be submitted to the Council. This was accordingly done and the report has been for some days in your possession. As two or three additional replies have been received since the report was circulated I propose to hold a meeting of the committee this afternoon, when the Council rises, to make a final adjustment, but I do not think that any material change will be made in the character of our recommendations. All the licensing bodies have now sent in answers to questions. Having an intimate bearing on this report is the amended scheme of professional study for students of the first year and the subjects of and mode of conducting the first professional examination of the Conjoint Board in England which has been adopted by the Royal Colleges of Physicians and Surgeons in London and was intimated to the Council three weeks ago. I do not propose to anticipate the statement which the representatives of the two Colleges intend doubtless to make on the amended scheme further than to say that the report of the Council's visitors to the first professional examination of the Conjoint Board has obviously been carefully considered by the Colleges, and that the suggestions made therein have been in several particulars adopted.

Certain Bills have been introduced into Parliament which bear on the Medical Acts. General Laurie has this session introduced into the House of Commons a Bill to meet the difficulty occasioned by one of the provincial Legislatures in Canada declining to renounce its present power of independent legislation and to consent to the formation of a Register for the whole Dominion, as is provided for, subject to the consent of the local legislatures, in the Canada Medical Act, 1902. This Bill provides that His Majesty may, if he thinks fit, declare by Order in Council that where any part of a British possession is under a central any somew al legislature, as is the case in Canada and previously been fees, the part under the local legislature shall fession. It is stat f the Medical Act, 1886, be deemed a did not accept an session. Should General Laurie's Bill nobleman well known of the Medical Act, 1886, could be medical education wa. applied to any province in Canada which, in the opinion of His Majesty, should afford to registered medical practitioners of the United Kingdom such privilege of practising in the province as to His Majesty might seem just. Bills have also been introduced during the present session of Parliament to facilitate the adoption of metric weights and measures in this country in substitution for our present methods. The interest which as a Council we have in such Bills is in connexion with the British Pharmacopœia and it is not unlikely that the Pharmacopœia Committee may refer to the subject in its report. Mr. Jackson has also given notice of a motion calling the attention of the Council to this matter.

[The PRESIDENT then referred to a statement privately circulated by him concerning the financial position of the Council, and also to certain offers to purchase the Oxford-street property of the Council which are to be considered *in camerâ*. He continued :]

Copies of a decision of the High Court of Justice in Ireland on a question submitted to the Court, whether the word "person" in Section 3 of the Dentists Act, 1878, means exclusively natural person or includes an artificial person, such as a corporation or company have, I understand, been sent to each member of the Council. The question arose in connexion with the case of O'Duffy *v.* Jaffe, when it was contended that the practice of dentistry could not be pursued by a company entitled *Jaffe, Surgeon Dentists, Limited.* The court decided that the Dentists Act as worded is directed against a natural person only and not against a company. The effect of this judgment is to show that a company practising dentistry cannot be prosecuted under the Dentists Act. Since the judgment in the case of O'Duffy *v.* Jaffe was given another case relating to the practice of dentistry by companies has been before the High Court of Justice in Ireland. The case arose on an application for the issue of a mandamus to compel in Ireland the Registrar of Joint Stock Companies to register under the Companies Act, 1862, the memorandum of a company to be styled "S. G. Rowell, Dentist, Limited." An elaborate judgment on the case was delivered by Chief Baron Palles who, with his colleagues, declined to grant the *mandamus*. The questions involved in these cases before the High Court of Justice in Ireland will be brought before the Council by Sir Charles Ball, who will move that the Council take action in terms of his motion. The Council will receive during the session reports from the Executive, Education, Finance, Public Health, Pharmacopœia, and other Committees. Thursday, May 26th, is set aside for the consideration of cases which have been under the consideration of the Penal Cases Committee, and it is satisfactory to note that in all probability they will not occupy more than one day of our sitting.

The President having been formally thanked for his address the Council proceeded with the business of the session.

Medical News.

SOCIETY OF APOTHECARIES OF LONDON.—At the examinations held in May the following candidates passed in the subjects indicated :—

Surgery.—C. W. S. Boggs (Section I.), Leeds; E. Morris, St. Bartholomew's Hospital; M. B. Potts (Sections I. and II.), Leeds; F. P. Rose, London and St. Mary's Hospitals; J. P. B. Snell (Section I.), Middlesex Hospital; M. C. Vivian (Sections I. and II.), Royal Free Hospital; and P. B. Whitington (Sections I. and II.), London Hospital.

Medicine.—A. J. Ambrose (Sections I. and II.), Westminster Hospital; W. S. Gibson (Sections I. and II.), Manchester and Middlesex Hospital; F. W. Higgs (Sections I. and II.), St. George's Hospital; M. B. Potts (Sections I. and II.), Leeds; G. W. Rogers (Sections I. and II.), Cardiff and St. George's Hospital; and A. B. S. Todd (Section I.), Leeds.

Forensic Medicine.—A. J. Ambrose, Westminster Hospital; J. B. Barnes, Manchester; L. F. Cope, St. George's Hospital; A. Lazar, Vienna and St. Mary's Hospital; M. B. Potts, Leeds; G. W. Rogers, Cardiff and St. George's Hospital; H. P. Shanks, St. Bartholomew's Hospital; A. B. S. Todd, Leeds; and S. H. R. Welch, Charing Cross Hospital.

Midwifery.—T. R. Roberts, London Hospital; and L. Sells, St. Thomas's Hospital.

The diploma of the Society was granted to the following candidates entitling them to practise medicine, surgery, and midwifery: W. S. Gibson, F. W. Higgs, and F. P. Rose.

TRINITY COLLEGE, DUBLIN.—At the final examination in surgery held at Trinity term the following candidates were successful :—

James G. Wallis, Herbert St. M. Carter, Henry M. Crawford, Wright Mitchell, Arthur W. Goldsmith, Charles J. Coppinger, David Gray, [illegible] ompson, Frederick W. Bury, John Harold T. Marrable, Wilfred L. [illegible]

Royal College of Surgeons in Ireland.—Fellowship Examination.—The following candidates having passed the necessary examination have been admitted Fellows of the College:—

L. E. Hardy, M.S. Edin.; J. P. L. Keegan, L.R.C.S. Irel.; R. H. Keenan, M.Ch. Dub.; J. C. Lavertine, L.R.C.S. Irel.; J. M. S. Lewis, L.R.C.S. Irel.; J. J. O'Hagan, L.R.C.S. Irel.; and H. Stevenson, B.Ch. R.U.I.

The following candidates passed the primary part of the examination.

E. H. F. Gilligan, H. M. Harrison, T. T. O'Farrell, G. Petit, and G. Sheppard.

Remarkable Vital Statistics of St. Petersburg.—An examination of the hygienic statistics affecting the city of St Petersburg discloses a most striking feature. Russia's capital from its rise down to the year 1884 appears as an "expiring community" and it is only since that happy year that the mortality became less than the births, which improvement has continued up to now. For the year 1903 the births of the St. Petersburg population amounted to 45,657 as against deaths 38,537. Since the filtering of the water-supply typhoid fever has attacked a much smaller number of people.

Sewage Purification Works at Davyhulme.—A report showing the progress made by the Manchester corporation at the works in connexion with sewage purification at Davyhulme was presented at the last monthly meeting of the Mersey and Irwell Joint Committee. The corporation desires to place second contact beds at Davyhulme and land which has been purchased at Flixton will be retained in order to carry out extensions if required. The corporation claims, moreover, that the volume of sewage per head of the population is much higher than in other towns, owing to water which has been used at works for cooling purposes getting into the sewers. Steps are now being taken to keep it out and so to lessen the volume of sewage. Manchester has had to bear much strong language and many fines for her delinquencies or *shortcomings as regards the purification of her sewage*, but she has done much with persistent perseverance towards removing this cause of reproach. This is agreeably shown by the change in the attitude of the joint committee towards the corporation, for it was unanimously decided to instruct the clerk to inform the corporation "that the joint committee are prepared to refrain from applying to the court for a period of six months if the corporation of Manchester will continue to make satisfactory progress in carrying out the scheme." It is also evidenced by the fact that the two bodies are now on visiting terms. The clerk of the joint committee said that he had received from Sir Bosdin Leach, chairman of the Manchester rivers committee, an invitation to the joint committee to inspect the works at Davyhulme, "which are by far the largest of the kind in the world," and it was arranged that the visit should be made early in June.

University of Oxford.—The Reader in Pathology gives notice that an election to a Philip Walker studentship in pathology will take place in the end of June next. The studentship has been founded "for the furtherance of original research in pathology." It is of the annual value of £200 (payable quarterly in advance) and is tenable for three years. The student may be of either sex and need not necessarily be a member of the University of Oxford nor be legally qualified to practise the profession of medicine. [illegible] of the student must be devoted [illegible] rch; no business or profession [illegible] d nor any educational or other work engaged in which in the opinion of the Reader in [illegible] Reader in Pathology but the student is bound to pursue these [illegible] least three terms of his [illegible] irement may, however, [illegible] If the work done by any student be of exceptional promise the studentship may be extended for a second period not exceeding two years. Intending candidates are requested to send letters of application, along with three testimonials (one of which should vouch for the candidate's personal character and general education), so that these shall be delivered to "The Reader in Pathology, University Museum, Oxford," on or before June 20th; ten copies of these papers must be submitted. Testimonials should be framed with a view to setting forth the candidate's capacity for undertaking research work. In the letter of application the candidate should state age, training, and particulars of any posts already held. Published records of work done may be submitted, but the previous prosecution of original research by a candidate is not essential to success. The full text of the regulations relating to the studentship will be found in the *Oxford University Gazette* of Feb. 2nd, 1904, and copies of these regulations can be had on application to the Reader in Pathology.

Association for Promoting the Training and Supply of Midwives.—A meeting of the council of this association was held by kind permission of Mrs. Charles Schwann at 4, Princes-gardens, London, S.W., on May 17th. The chair was taken by Miss Wilson, president of the Midwives Institute and member of the Central Midwives Board. Several well-known ladies and gentlemen were present. Mrs. Wallace Bruce, the chairman of the executive committee, stated in her report that Mr. Arthur A. Leon, L.C.C., had consented to become treasurer of the association and that Mr Cosmo Bonsor (treasurer of Guy's [illegible] r. R. N. Salaman [illegible] ance committee. [illegible] had been drawn up to secure midwives for nursing among the poor. Free or assisted training was given by the association to candidates willing to bind themselves to district midwifery for a definite period. Training vacancies [illegible] mittee at Queen Charlotte's [illegible] York road, the East End [illegible] Maternity Hospital, and the [illegible] Home. Reference was made [illegible] Ham in connexion with th [illegible] started by the association last year. Since the opening of the home in November, 1903, 189 infants had been under the care of the midwife-in charge and the pupils under training and more than 4000 visits had been paid. An immense *amount of good* had been done to many mothers and infants and it had proved an excellent training ground for the pupils. The cost of 16 weeks' training, with board and lodging, is £19 6*s*. 8*d*. It was stated that the question of finance was one of great anxiety to the executive committee. The sum of £1000 would train 50 midwives and it was felt that a direct appeal must be mad [illegible] nucleus of a training fund. [illegible] encouraged by some generou [illegible] had been [illegible] with local authorities various m [illegible] and other [illegible] nd it was resolved, on the motion of Lady Balfour of Burleigh, "that a large public meeting be held in the autumn." This was seconded by Dr. Salaman, who considered that healthy infants were the mainstay of the nation and as needful as an efficient army. The annual meeting of subscribers and friends of the association will take place early in 1905. The office of the association is at 12, Buckingham-street, Strand, W.C.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Manufacture of Serum.

When the House of Commons reassembles after the Whitsuntide recess Mr. Robert Cameron will ask the Home Secretary whether his attention has been called to the report of the Lister Institute of Preventive Medicine, in which it is admitted that the injection of antitoxin causes a large number of rashes, inflammation of joints (ascribed to something inherent in the serum of the horses or other animals), and also an increased number of cases of paralysis; and whether, in view of this statement, he will consider the advisability of taking steps to prohibit the manufacture of serum in laboratories licensed under the Vivisection Acts.

Medical Examination of School Children.

Sir Hugh Shaw Stewart proposes to move the insertion of a new clause in the Education (Scotland) Bill when that measure gets into committee, giving power for the public health inspection and supervision of schools and the medical examination and supervision of school children. The proposed clause reads as follows: "It shall be the duty of each local authority acting within a school board area to cause a systematic supervision to be exercised over the health conditions of the schools within their district which are under the jurisdiction of the school board, and it shall be the duty of the medical officer of the local authority, in addition to any special reports which may be required, to report in the month of January in each year to the local authority as to the health conditions of the schools within their district, and particularly as to (*a*) the lighting; (*b*) the heating and ventilation; (*c*) the condition as to cleanliness; (*d*) the sanitary conveniences; and (*e*) any action which he has taken in the course of the preceding 12 months with respect to infectious disease in connexion with schools. The local authority shall forthwith transmit to the school board and to the Education Department a copy of this report. It shall be the duty of the local authority to carry out a system of medical examination and supervision of the children on the registers of the schools within their district upon such lines and in such a manner as the Education Department may prescribe, and to supervise the health conditions of the schools, and it shall be the duty of the local authority to appoint such medical inspectors as may be necessary for the proper medical examination, inspection, and supervision of the children and schools, and such examination, inspection, and supervision shall be carried out under the supervision of the medical officer of health. The local authority shall forthwith transmit the reports of the medical inspectors to the school board. In consideration of the inspection and supervision of the health conditions of schools and of the medical examination and supervision of school children thus devolving upon the local authority, the Education Department shall each year pay to the local authority out of the education fund such sum as shall adequately meet the cost involved, upon a scale to be fixed by the Secretary for Scotland, having regard to the particularity of the medical examination required and the amount of work involved, on the basis of a payment per pupil upon the registers of the schools within the district of the local authority, always provided that the Education Department may withhold such payment if the department is of opinion that the inspection and supervision of the schools and school children within the district of any local authority has been inefficient. It shall be the duty of the school board to report forthwith to the local authority all cases in which the reason assigned for the absence from school of a child is the existence of infectious disease in the household."

The New Lunacy Bill.

As stated in THE LANCET of May 21st the Attorney-General was prevented from explaining the provisions of the Lunacy Bill which he introduced on Wednesday, May 18th, owing to the operation of one of the new rules of procedure. On Thursday Dr. FARQUHARSON drew the attention of the House to the inconvenience thereby caused. He remarked that he had never known legislation to follow so quickly on a debate in the House, but the Attorney-General could not "condescend to particulars," as they said in Scotland. The Bill provided a great improvement in the treatment of lunacy, its object being to assimilate the English law to the Scottish, to enable patients to be treated in a better way and to give them a chance to return to sanity. The Attorney-General—who, Dr. Farquharson reminded the House, is a graduate in medicine of Edinburgh as well as a lawyer—afterwards told the honourable Member that he regretted he had not had an opportunity of describing the Bill, which "would create almost a beneficent revolution."

HOUSE OF COMMONS.

WEDNESDAY, MAY 18TH.

Alleged Violation of the Lunacy Act.

Mr. CORRIE GRANT asked the Home Secretary whether he was aware that Mrs. Helen Meredith was detained in Bethlehem Royal Hospital from August 17th to Sept. 25th, 1903, without being taken before or visited by a judicial authority as prescribed by Section 8 of the Lunacy Act, 1890, although she signed immediately on her admission on August 17th, 1903, a notice of her desire to be taken before or visited by a justice, judge, or magistrate having jurisdiction in the district within which she was detained; and, if so, whether he would say who was responsible for this violation of the Lunacy Act [illegible] take to prevent a repetition of it.—Mr. [illegible] I understand on inquiry that the facts are [illegible] but the delay was due to a cause for which the hospital authorities were not responsible. They forwarded the notice given by the lady in question without delay to the clerk to the justices and it was in his proceedings for procuring the attendance of a justice that the difficulty and delay occurred. I am making further inquiries with the view of ascertaining whether any steps can be taken to prevent the recurrence of such a case.

THURSDAY, MAY 19TH.

The Case of Dr. Kirwan.

Mr. SLOAN asked the Chief Secretary to the Lord Lieutenant of Ireland whether his attention had been called to the fact that, at a meeting of the committee of management of the Ballinasloe District Asylum, held on May 9th, a letter was read from the Lord Lieutenant asking to be informed why, in electing Dr. J. St. L. Kirwan to the vacant office of resident medical superintendent, they had passed over the senior assistant medical officer of the asylum; whether information was refused to the Lord Lieutenant; and if so, what action, if any, he intended to take in the matter.—Mr. WYNDHAM replied: The effect of the Lord Lieutenant's letter is correctly stated in the first part of the question. The request for information was not refused. The committee of [illegible] the right of the Lord Lieutenant to invite it [illegible] ated that Dr. Kirwan, the junior assistant, b[illegible] ted by it. Section 84 (4) of the Local Govern[illegible] provides that the resident medical superintendent shall not be appointed without the concurrence of the Lord Lieutenant. The statement that Dr. Kirwan was duly appointed by the committee is, therefore, inaccurate inasmuch as it is incomplete. The right vested in the Lord Lieutenant of granting or withholding his concurrence is unconditional. In exercising that right his Excellency discharges a duty imposed upon him by statute and that duty is not limited to ascertaining whether the candidate whose appointment is submitted is possessed of the statutory qualifications for the post. The circumstances of each case must be considered. The committee has declared that Dr. Kirwan was elected because, in its judgment, he was considered to be the fittest for the position. The selection of a junior officer, however well qualified, is of doubtful expediency, but in view of the fact that promotion by seniority is not laid down in the Act, and though of general is not of universal advantage, his Excellency does not feel called upon to express an opinion on the view put forward by the committee which is primarily responsible. In these circumstances his Excellency is not prepared to withhold his statutory concurrence in the appointment and the committee has been informed accordingly.

Advice as to Vaccination.

Mr. WEIR asked the President of the Local Government Board whether he was aware that, although forms were framed by the Local Government Board for distribution to the parents of newly born infants, the vaccination officer of Brighton had induced the superintendent registrar to issue a form in which the vaccination officer gave his private advice in regard to vaccination; and, if so, whether steps would be taken by the Local Government Board to insure its forms being issued intact.—Mr. LONG replied: I understand that the guardians of the parish of Brighton recently had this subject before them and resolved that the vaccination notice should be issued in the form previously in use in the parish with the omission of a notice printed on it to the effect of its being advisable that children should be vaccinated between the second and third months after birth. I am not aware of any sufficient reason for objecting to the document as altered and I do not propose to interfere in the matter.

Vivisection.

Mr. WEIR asked the Home Secretary whether he had yet received the report of the committee appointed by the Royal College of Physicians to ascertain whether, in its judgment, experiments on living animals before classes were necessary for the education of medical students; and, if so, whether he would state the nature of the opinion expressed.—Mr. AKERS-DOUGLAS replied: I presume the honourable Member refers to the special consideration which the Royal College of [illegible] to the question whether experime[illegible] anæsthetics) were necessary for the [illegible] I have received the opinion of the [illegible] to the effect that science can only be adequately taught with the aid of demonstrations which involve, in the case of physiology and pharmacology, experiments on living animals.

Uncertified Deaths in Scotland.

In the general discussion that arose [illegible] adjournment Mr. WEIR called attention [illegible] tified deaths in Scotland.—Mr. GRAHAM MURRAY [illegible] be a useless expenditure of money to insist by law that every death should be certified by a medical man. There was ample protection against crime in the inquiries of the procurator-fiscal.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

BRUNTON, Sir LAUDER, F.R.S., has been elected Consulting Physician to the Infants' Hospital, London, N.W.

CHASTEL DE BOINVILLE, VIVIAN, M.B., Ch.B. Edin., has been appointed Assistant Director of Cancer Research, Liverpool University.

CLARKE, J. JACKSON, M.B. Lond., F.R.C.S. Eng., has been appointed Surgeon to the North-West London Hospital.

MACKENZIE, JOHN ALEXANDER, M.A., M.B., Ch.B. Aberd., has been appointed Resident Medical Officer at the General Infirmary, Oldham.

SIBLEY, W. KNOWSLEY, M.D. Camb., M.R.C.P., has been appointed Physician to the North-West London Hospital.

SUTHERLAND, G. A., M.D. Edin., F.R.C.P. Lond., has been appointed Physician to the North-West London Hospital.

TE[illegible] F.R.C.S. Eng., has been appointed [illegible] don Hospital.

WA[illegible] been appointed Clinical Assistant to [illegible] n.

WIL[illegible] B.S. Lond., M.R.C.S. Eng., L.R.C.P. Lond., has been appointed District Medical Officer and Public Vaccinator to the Walsham-le-Willows District of the Stow Union.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

Notes, Short Comments, and Answers to Correspondents.

THE "OPHTHALMIC OPTICIAN."

WE have received a little leaflet sent out by that enterprising advertiser Chas. F. Forshaw, M.S.A., or Forshaw and Co., or Dr. Forshaw, for he gives himself all three titles. From it we learn that "Dr. Forshaw has absolutely nothing antagonistic to say against the qualifications of Country Opticians generally but he desires to point out...... that ours is an extensive and up-to-date Optical practice and we mean to keep it so." Forshaw is an amusing quack and has managed to get a testimonial from four Bradford medical men. Three of these—namely, Mr. A. Ramage, Mr. W. J. Mullany, and Mr. J. Bradley—we have been able to find in the Medical Directory and in the Register, but the fourth, Dr. C. McDowell, is neither to be found in the Directory nor the *Register*. Forshaw was dispenser at the Bradford Eye and Ear Hospital for some 16 months and the four medical men *imply* that this appointment gave "Dr. Charles Forshaw great experience in diseases of the eyes," while another testimonial from the Hon. F. H. Pollexfen, who states that he is a notary public and a master *extraordinary in the High Courts of Chancery*, besides being a member of the Spectacle Makers' Company, mentions that Forshaw's "experience as dispenser at the Bradford Eye Hospital is unique in the annals of optics." We cannot find Mr. Pollexfen's name in the Law List, but then he may be a colonial notary. His Grace the Archbishop of Armagh also gives a testimonial, but whether this confiding cleric is the prelate of the Church of Ireland or the Roman Catholic Archbishop there is nothing to show. Finally, Forshaw states with pride that he is ophthalmic optician to his Lordship the Marquis de Leuville. Forshaw has learned wisdom in one point. He does not put drops into the eye. But why he should be allowed to call himself doctor and why any medical man should give him a testimonial we cannot understand.

A CHINESE PHYSICIAN.

THE contrast between precept and practice in the Far East is sometimes puzzling to the Western mind. We have heard much of late

physicians to be little better than savage medicine men. Our quotation is from Colonel Yule's notes on Marco Polo's "Voyages":—"In my own town," says the Buddhist writer cited by Colonel Yule, "there lived a physician by name Chang-yang-ming. He was a man who never took payment for his treatment from anyone who was poor; nay, he would often make presents to such persons of money or corn to lighten their lot. If a rich man would have his advice, and paid him a fee, he never looked to see whether it was much or little. If a patient lay so dangerously ill that Yang-ming despaired of his recovery, he would still give him good medicine to comfort his heart, but never took payment for it. I knew this man for many a year, and I never heard the word *money* pass his lips! One day a fire broke out in the town and laid the whole of the houses in ashes, only the house of the physician was spared." Colonel Yule comments thus on this passage: "Of such as this physician the apostle said: 'Of a truth I perceive that God is no respecter of persons, but in every nation he that feareth Him and worketh righteousness, is accepted with Him.'"

ENTERPRISE.

To the Editors of THE LANCET.

SIRS,—As the writer of the letter in THE LANCET of May 7th headed "Enterprise" my inquiry was directed to a point of professional etiquette only. I had no desire to question the qualifications and *professional status of the specialist referred to*, and if any words of mine have caused annoyance or injury to this gentleman I regret them and apologise

I am, Sirs, yours faithfully,
H. I. L.

May 21st, 1904.

THE "METBAIN" COVER.

WE have received from the "Metbain" Cover Company of Accrington a specimen of a contrivance invented by them which they are putting on the market and which would enable each user of a public water-closet to place a fresh sheet of tissue paper on the seat as a seat cover. A number of sheets of tissue paper cut in crescented form with the horns of the crescent folded the one over the other are inclosed in a U-shaped metal cover, to one end of which the papers are fastened in the centre by a flap, thus securing them firmly in the centre to the cover. This metal cover with its contents is to be suspended by a metal bracket or handle, to be screwed to the under and front side of the wooden seat of a pedestal closet in such a way that the case in no way projects beyond the front edge of the closet seat. At the back of the cover there is a spring clip which engages the bracket and from which it may be detached with a slight effort and the cover removed if necessary. When the seat is required for use one of the papers is eased out of the case and the horns of the crescent unfolded and placed *on* the seat. The paper is kept from being dislodged by being gripped in the centre by the metal cover, as explained above. After use the paper is torn off. The contrivance seems to us likely to be useful and may supplant the daily newspaper which is used by some people for the purpose. The only objections to it that we can see are that tissue paper soon becomes wet and that for wooden seats of pedestal closets which are raised and thrown back it might be rather inconvenient to have the metal cover fixed to the seat.

ANKYLOSTOMIASIS IN CENTRAL AMERICA.

Dr. Joseph A. Capps of the Rush Medical College, Chicago, has published what he believes to be the first recorded case of ankylostomiasis occurring in the neighbourhood of the Panama Canal. The disease is well known to be far from uncommon in the West Indies and in the southern States of the American Union. In Great Britain the usually accepted name of the parasite is ankylostomum but in America uncinaria—i.e., hook-worm—is more in favour. Following the latter nomenclature Dr. Capps says that the two species of hook-worm which infect man are uncinaria duodenalis, or the old-world hook-worm discovered by Dubini of Milan in 1838, and uncinaria Americana, recently identified by Stiles as a new-world species and described by him in *American Medicine* of May 10th, 1902. Dr. Capps's patient was a man, 52 years of age, and a native of the United States. He enjoyed excellent health until 1879, when he went to Panama to work as a carpenter. In 1900 he was first taken ill with sudden gastro enteric symptoms. At that time he was employed on the Chagres river (on the Isthmus), where he handled logs that were often covered with mud and he frequently took food without previously washing his hands. From January, 1901, to April, 1902, he was in a hospital in New Orleans where his illness was considered to be pernicious anæmia On Sept. 9th, 1902, he was admitted into the Cook County Hospital where Dr. Capps had opportunities of observing him and the diagnosis of uncinariasis which was suspected from the existence of eosinophilia in the blood was confirmed by the discovery of *ova* in the *fæces*. At the necropsy about 150 specimens of uncinaria duodenalis were found in the small intestine.

HOLMAN TESTIMONIAL FUND.

THE following additional subscriptions to the above fund have been received:—

	£	s.	d.		£	s.	d.
Dr. F. Taylor	3	3	0	Mr. G. Stawell (O.E.) ...	1	1	0
Mr. J. W. Lowder Cooper (O E)	0	10	6	Dr. C. M. Chadwick (O.E.)	1	1	0
Dr. A. B. McCarthy (O.E.)	0	10	6	Mr. G. H. Makins, C.B.	2	2	0
Mr. Harold Lawton (O.E.)	1	1	0	Mr. Stamford Felce ...	1	1	0
Mr. H. Martin Francis (O.E)	0	10	6	Balance of Council's testimonial to Dr. Holman (1903), per Mr. Stamford Felce	6	9	0
Mr. Percival E. Francis (O.E.)	0	10	6	Mr. A. Kelsey	2	2	0
				Dr. A. P. Hillier	1	1	0

Further subscriptions will be received by Dr. John H. Galton, Chunam, Sylvan-road, Norwood, S.E., or by Mr. W. A. Berridge, Oakfield, Redhill, Surrey, and a further list will be published in a month. The amount at present subscribed is £353 3*s.* 6*d.*

INCOME-TAX ASSESSMENT.

To the Editors of THE LANCET.

SIRS,—A and B are in partnership but are assessed separately for income-tax purposes. They take into the business a third partner, C, with the understanding that C shall leave them at the end of the first year if the arrangement does not prove satisfactory to all parties and that any moneys which C may have drawn shall be made up to a certain sum by A and B in return for his services during the year of trial. C retires at the end of the year. Are A and B entitled to deduct the sum paid to C during the year he assisted them in estimating the profits derived from the business for income-tax purposes?

I am, Sirs, yours faithfully,

Y. Z.

⁂ C being a partner, though only for the year, should be separately assessed, as A and B are. The sum paid to C may not be deducted from the business account in estimating the profits, as C was a partner.—ED. L.

AN IMPROVED TEA AND COFFEE INFUSER.

THE preparation of tea in large quantities for use in hospitals, asylums, schools, and other institutions is often a matter of considerable difficulty. The practice of infusing the tea in a large boiler and then adding milk and sugar saves time but the liquid thus produced is not at all agreeable to the palate and is far from being conducive to health. On the other hand, the use of a number of small pots means increased expense, loss of time, and a certain amount of waste. Dr. W. Reid, the medical superintendent of the Royal Asylum, Aberdeen, has sent us a description of an infuser for tea and coffee which he has had made for the institution with which he is connected and the apparatus would appear to answer admirably the purpose for which it is intended to serve. It has already been favourably commented upon by the Commissioner in Lunacy. This infuser consists of an earthenware vessel contracted at the top and having a dome-shaped lid. At the bottom of the vessel there is a tap for drawing off the contents. Provision is made within the lid for suspending a muslin bag containing the tea leaves or coffee. This bag is removed when the tea or coffee is sufficiently infused. Outside the earthenware vessel is a metal case of the usual urn-shape and between the vessel and its outer case a layer of cork dust is put to act as a non-conductor of heat. The infusion can thus be kept hot for some time. If it is required to keep the tea or coffee hot for a longer time a spirit lamp can be placed under the urn. Messrs. Marshall and Philip of 125, Union-street, Aberdeen, are the makers of this urn which has been named the "Balmoral." The price of an apparatus holding about one and a half gallons is 30*s.*

AN UNFORTUNATE TESTIMONIAL.

WE have received a copy of the *Birmingham Express* in which Messrs. H. Andiamio and Co., a firm of tobacconists carrying on business near Congleton in Cheshire, advertise their "Marsūma" products and, moreover, publish a most eulogistic testimonial from a medical man in Herefordshire (name and address, of course, given in full). This gentleman says: "I advise mankind to smoke one brand only—that brand, 'Marsūma.'" We think he would be well advised to insist on the withdrawal of this announcement.

A COOLING CUSHION.

Messrs. L. Paechtner and Co., of 40, Queen-street, Cheapside, London, E.C., desire us to say that they are now the sole agents for Great Britain and the Colonies for the "Cooling Cushion" referred to in THE LANCET of April 16th last.

◆

Schoolmaster.—Provided that the "covered way" has only a roof and no sides and that the sick house is *not less* than 30 feet away from the main buildings we think that in view of the conveniences obtained with regard to ease of transport and facilities for water- and gas-supply the connected sick house would be quite as hygienic as the totally separate one. Our correspondent may use the answers in the way in which he suggests. He will find a supply of useful information in two pamphlets published by the Medical Officers of Schools Association: (1) "The Arrangement and Construction of School Sanatoria," by Charles E. Paget (London: J. and A. Churchill); (2) "The Construction and Maintenance of School Infirmaries and Sanatoria," by the Council of the Medical Officers of Schools Association (London: J. and A. Churchill).

Justitia.—Upon the law of the matter our correspondent must consult a solicitor. His position is regulated by the conditions upon which he sold his practice. From the ethical point of view we cannot advise his return to the place.

Ferratus.—It seems that medical men, wanting certain facilities in electrical treatment, have employed the institute in question. Usually the patient has gone there on his or her own initiative.

Consistent does not inclose his name or address. He will find the subject to which he refers fully dealt with in the columns of THE LANCET of April 9th.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (30th).—London (2 P.M.), St. Bartholomew's (1.30 P.M., St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private informa-
d addresses of
s.
e.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

Will Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, MR. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Sons and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 31 Rue Bapts Asnières, Paris.

The Hunterian Lecture

ON

INTERMITTENT HYDROPS OF THE JOINTS: AND THE INFLUENCE OF GROWTH ON DEFORMITIES.

Delivered at St. George's Hospital on May 25th, 1904,

BY HOWARD MARSH, M.A., F.R.C.S. ENG.,
PROFESSOR OF SURGERY IN THE UNIVERSITY OF CAMBRIDGE.

MR. CHAIRMAN AND GENTLEMEN,—When your Dean conveyed to me the wish of your council that I should deliver the Hunterian lecture this year he informed me that there were no conditions necessary to be observed and that the matter was entirely in my own hands. In these circumstances it devolved upon me to select some material which might be worthy of your attention. But, further, I had to remember that the name of Hunter would stand inscribed before me, so that I must, in however small a degree, yet as far as possible, show myself one of his disciples by endeavouring to contribute something to our knowledge in the field of surgery. There are two subjects which have lately attracted my attention and a discussion of which, I hope, you may find of sufficient interest to justify me in having chosen them. I have taken (*a*) intermittent hydrops of the joints; and (*b*) the influence of growth on deformities.

Intermittent hydrops of the joints is certainly a remarkable affection. By way of introduction I will read two examples of it which have come under my own personal notice.

CASE 1.—A man, aged 38 years, a patient of Dr. E. J. Tatham of Cheltenham, was kicked on the knee by a horse in December, 1902. Some effusion followed, but under treatment the joint soon apparently recovered. In April, 1903, while the patient was in Scotland the knee became so painful that he could get very little sleep. There was no marked swelling or other objective symptom. Pain shortly afterwards subsided, but when he was at Henley a few months later it returned and was so severe that hypodermic injections of morphine were used. Swelling was slight and there was no heat of the surface. As the condition was supposed to be due to rheumatism blisters were used but without benefit. Later, the joint was stiff and more swollen. It was put into a splint and he went about on crutches. Improvement slowly followed and in a month he could walk a little on the limb. In September he had hot-air baths and some massage, but the joint became extremely painful and so much swollen that it measured two inches in circumference more than the other knee. This swelling, however, soon subsided and when I first saw him early in October, 1903, he stated that three weeks before the joint was quite well, though the limb was weak and painful. On inspection the joint appeared natural. It was free from heat and there was then no swelling. Passive movements were perfectly free and smooth, but the muscles were considerably wasted and so powerless that when he was lying he could not raise his heel off the surface of the bed, and he carried a crooked stick to lift his foot when he was sitting and wished to change its position. He said that at night he had such agonising pain in the limb from the hip to the ankle that it was like being on the rack, and I entered in my notes that his complaints of pain in their apparent extravagance resembled those of a hysterical woman. As the case was one of unusual character he came to London for further observation. On the morning of the day after his arrival the sister of the surgical home reported that all through the night he had been in very severe pain and had scarcely slept at all. I found the knee only slightly swollen, free from heat, and as before readily allowing passive movement from very nearly full extension to almost complete flexion. He was himself unable to move it. He looked worried and depressed, complained bitterly of pain, and said that something must be done for his relief. He was even ready to submit to amputation. During our conversation he remarked that swelling became much more marked *every night* and he asked me to see him on that evening at six o'clock. On doing so I at once found that the knee had undergone a remarkable change since the morning, for it was now so considerably swollen that it was an inch and a half larger than its fellow and the swelling was such as I had never before met with. It followed exactly the outline of the synovial membrane, and within this area it was so abrupt and prominent that the knee had a remarkable globular appearance and the patella was pushed forwards in a very unusual manner. There was no fluid in the cavity of the joint and the swelling seemed to be due to mere vascular turgescence and engorgement of the synovial membrane, which appeared at least half an inch thick. The surface was a little over-warm and slightly dusky. He now repeated his statement that the joint swelled up in this way regularly every evening and then gradually reassumed a natural appearance. Hearing of this quite definite periodicity I was reminded of ague and I asked him if he had been abroad. I found that he had been, that he had often had malaria, and that he had taken large quantities of quinine, but none since the knee had been in its present state. In these circumstances I ordered him ten grains of quinine twice a day. On the next morning I was told that he had lost his pain and had slept all through the night and until 10 A.M. He looked like another man; he was fresh and bright, and said it was the first night of freedom from pain he had had for eight months. He continued the quinine. His pain did not recur and the attacks of swelling diminished, and in four days, as there seemed no reason for keeping him in town, he returned home to be under Dr. Tatham's care. He soon regained some power in the extensor muscles and could raise the limb by a voluntary effort. The joint remained about half an inch larger than the other. Three weeks later the patient wrote: "The knee is progressing very satisfactorily. I have no sign of puffing towards evening and am able to bend it almost as easily as the other. I went a three mile walk last week without inconvenience. I am still quite free from pain, except a little down my leg and in my ankle. I feel so strong on my knee that I think I could walk on the hills, but Dr. Tatham thinks I had better defer that pleasure for a little." Shortly after this Dr. Tatham wrote that "the patient is able to be about practically all day without bad results. The joint is only three-eighths of an inch larger than the other and even after exercise there is no increase of size. He has *no* pain. There is more tone in the thigh muscles and less wasting, although the thigh is still markedly smaller than the other." Three months later Dr. Tatham wrote: "There have been some fresh developments in the case since I last reported. The patient managed to get influenza about a month ago. Simultaneously the knee-joint increased somewhat in size but in itself was not painful. However, there was shooting and burning pain, coming on especially at night, above and in front of the internal malleolus, accompanied by distinct swelling, the skin itself being exceedingly hyper-sensitive. Also there was pain which started just behind the great trochanter and extended upwards to the posterior part of the iliac crest. These pains were described as intense. They gave way to five grain doses of phenacetin. The knee remains three-eighths of an inch larger than the other. The pain in the region of the inner ankle is better, but not gone, and the patient has to lace that boot more loosely than the other. The swelling there has gone. The pain at the back of the hip has gone. He is able to walk six or eight miles without subsequent swelling of the knee. The thigh muscles are still very wasted." Writing a few days ago Dr. Tatham reports that the knee is as good as the other and muscular wasting is only very slight.

CASE 2.—A young woman, aged 28 years, who looked well and robust, was admitted into St. Bartholomew's Hospital in March, 1903, for advice about her right knee-joint. She stated that for the last 18 months the knee every 14 days became swollen and somewhat painful. These symptoms, with the most marked regularity or periodicity, lasted three days and then disappeared, leaving the joint in a perfectly normal condition. The attacks corresponded with the menstrual periods and with the mid-periods between them. The patient's statements were fully borne out by what was observed while she was in the hospital, where she remained six weeks. During this time two attacks showed exact periodicity; the third, however, was one day late, that is, it occurred not on the Saturday when it was due but on the Sunday. The attacks were exact repetitions of each other. The joint became stiff and uncomfortable and the seat of effusion, so that the synovial cavity was uniformly and somewhat tensely distended. The joint was tender and the temperature of the skin over it was slightly raised. The patient was kept in bed, but the attacks still recurred as regularly as before, though they were rather less marked and of rather shorter duration. Some fluid was removed from the joint and examined. It was merely synovia diluted with serum. There was no blood and no micro organisms were present. Quinine had no effect. Various forms of local treatment were tried but were useless. On leaving the hospital the patient went to Lowestoft and was treated with arsenical solution. The attacks gradually declined in severity and at length ceased and she returned to her employment in London. At present, after the lapse of eight months, there has been no return.

These two are the only examples of periodic swelling of joints that I have met with or, at all events, recognised. Yet many cases are to be found in surgical literature which present the same feature of attacks which are periodic in their occurrence and which generally consist of a considerable effusion into the cavity of the synovial membrane; but sometimes, as in Case 1, of swelling not dependent on effusion but on turgescence of the synovial membrane sometimes combined with œdema of the neighbouring structures; while between the attacks the joints are in a normal condition or only weak. In the *Boston Medical and Surgical Journal* for 1901, vol. cxlv., p. 484, Dr. Brackett and Dr. Cotton have collected all the cases they have been able to find and have discussed them in a valuable and very instructive paper under the title of "Intermittent Hydrops." They found in all 68 cases but some of these were doubtful. When the doubtful examples were excluded there remained 43 clear instances, which, though differing in detail as to the particular joints or the number of joints involved, the period of return, and collateral symptoms—pain, heat, &c.—yet showed the distinctive feature of periodic attacks alternating with clear intervals Many of the following particulars in regard to this group of cases are taken from the paper of Dr Brackett and Dr. Cotton.

As to the local condition, this usually consists of an effusion into the cavity of the joint concerned. This may be small in amount but in some cases the cavity is tensely distended so that there is considerable pain. The fluid removed from the knee-joint in one of my cases was sterile and apparently merely diluted synovia. In a few instances, as in my first case, while there has been little or no effusion into the joint concerned, the synovial membrane has been swollen and the surrounding tissues have been œdematous. No case of suppuration or the formation of adhesions suggesting any inflammatory changes has, so far as I know, been recorded In my first case there was a patch of œdema of the skin in the lower part of the leg.

The joint most frequently involved is the knee Often both knees are affected and are the only joints attacked. But all the large joints—the hip, the ankle, the shoulder, the elbow, and the wrist, and even, Dr. Brackett and Dr. Cotton state, the lower jaw joint and the joints of the spine—may be concerned. The condition may be limited for some years to one particular joint, or several joints may be attacked simultaneously or alternately, or many joints may be attacked in succession. The attacks reach their height in the majority of cases in two days and then subside in two days, so that they extend in all over four days. Yet the attacks may be much shorter. In my first case swelling began at about 4 P.M. and passed off again by about 6 A.M., thus lasting in all about 14 or 15 hours. The time of recurrence of the attacks varies widely in different cases. In Case 1 the attacks recurred every evening. In some an attack takes place every third or fourth day; in some only once every month. In Pletzer's and Seeligmüller's cases there was an interval of three months. The period of recurrence most commonly observed is between the ninth and the fifteenth day. In some cases the period changes. In one it changed from the thirtieth to the ninth day. In another from three months to 11 days. The affection is slightly more common in the female sex As to age, although a doubtful case has been reported in a girl aged nine years, only three cases began as early as the fifteenth year. One patient was 64 years old. The affection most commonly begins about the twenty-sixth year. Although in some instances the attacks have corresponded with the menstrual periods in many others there has been no such coincidence. In reference to this point it seems interesting to recall the circumstance that the late Dr. W. M. Ord recorded some cases in which patients had somewhat painful swellings of the joints at each menstrual period. I have for many years watched for similar cases but I have never met with them. May it not be that Dr. Ord's cases were examples of intermittent hydrops the recurrence of which and of the menstrual periods were the same?

Although it will involve some repetition I shall now venture on a few additional remarks on my first case because, while its accurate periodicity stamped it as belonging to the group under discussion, the character of the swelling of the knee differed from that which is usually observed and also because the case presented several features beyond the condition of the joint which, although absent in many instances, must yet be borne in mind as parts of the general picture. Unless they are remembered the more rare forms of the affection are apt to be overlooked. The enlargement of the knee was not due to effusion into the joint; no fluid was present It was the result of engorgement of the synovial membrane while a similar disturbance of the circulation in the subcutaneous tissue of the lower part of the leg, adjacent to but not involving the ankle-joint, was observed by Dr. Tatham. Not having met with these periodic joint cases before and as the patient in Case 1 had often had severe malaria I at first supposed that his case was an instance of malaria involving a joint, and this impression seemed to gain ground when quinine was found to produce so immediate and powerful an effect. There were two further points which turned my thoughts to malaria.

First, many years ago I read of the following remarkable cases I can mention only the main facts, for I have no recollection as to where they were recorded and I regret that I have not been able to find them. In a malarial district two soldiers underwent amputation through the thigh. In both for several days the stump each day became dusky, painful, and engorged and then dripped blood freely. The patients became so exsanguine and exhausted that their lives were in great danger. Then, because they were so prostrated and were known to be the subjects of malaria they were treated with full doses of quinine. The result in both cases was immediate The vascular disturbance of the stump ceased, hæmorrhage was arrested, and both patients recovered. The local disturbance of the circulation which occurred in these instances is perhaps similar to that in some cases referred to by Dr. Hilton Fagge[1] in which patients suffering from malaria have been attacked with coma. "Hertz says"—I am quoting from Fagge—"that instances of this are from time to time sent into the hospital under his care for apoplexy and Graves placed on record a case in which he made this mistake. A gentleman awoke about 4 A M with sensations of malaise, chilliness, nausea, and headache. After an hour he became extremely hot, the pain in the head was intense, and he passed from a drowsy condition into one of complete coma with deep snoring, so that he appeared to be labouring under a severe apoplectic fit. He seemed to derive much advantage from bleeding and other remedies and in the evening he was perfectly well. The day but one after the same symptoms returned and were removed by the same treatment, but when a third attack came on Graves saw that it was an example of *tertiana soporosa* and cut it short by large doses of quinine."

Secondly, the presence in my case of severe neuralgia could, I thought, reasonably be regarded as suggestive of malaria, for in cases of what has been termed masked ague the paroxysms may be, as Fagge states, "of the most diverse description and attended with scarcely any febrile disturbance, or even with none at all. The most important of these paroxysms is neuralgia, occurring especially in the region supplied by the first division of the fifth nerve, and thus often called brow ague, ... while cases of sciatica and other neuralgic affections of the limbs have been attributed to ague." In my case pain was intense. Nor was it confined to the knee or primarily dependent on the joint affection. At one time it involved the lower part of the leg, where it was associated with swelling of the skin and subcutaneous tissue—a distinct local vascular disturbance—and with hyperæsthesia of the surface. At another time it extended from the iliac crest to the great trochanter. Thus the pain (in Case 1) was similar to that which has often been met with in malaria. I found, however, when I consulted Sir Patrick Manson that he knew nothing of any affection of

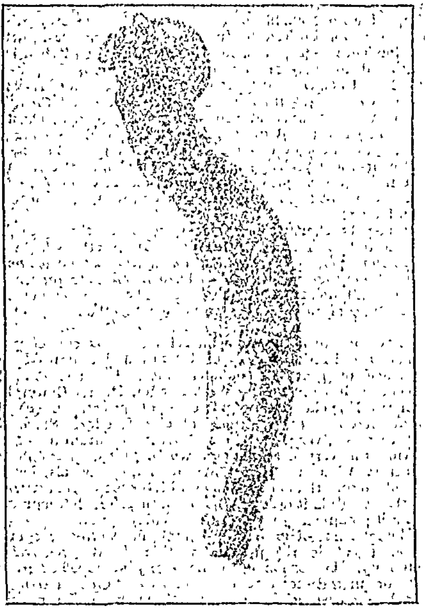
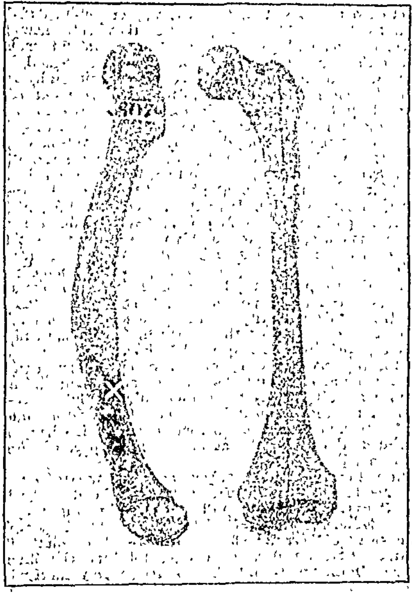
FIG. 1.



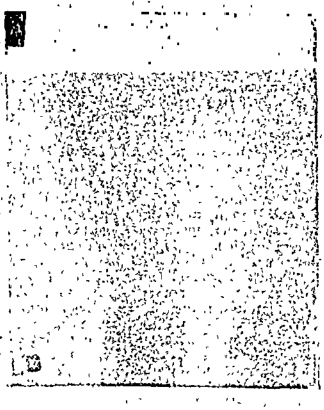
A rickety femur showing a strong buttress of compact bone in the concavity of the curve.

FIG. 2.



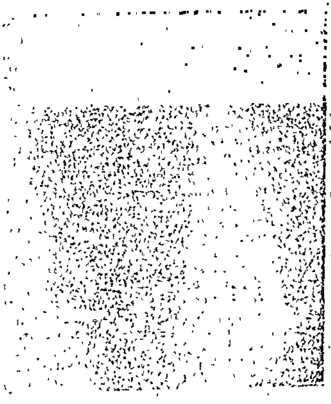
Photographed from specimen in the Museum of St. Bartholomew's Hospital. Left femur of a child, aged seven years, in whom Macewen's operation for genu valgum had been performed three years previously. A slight heaping up of cancellous tissue at the point marked × indicates the site of operation.

FIG. 3.



Skiagram from a case of osteotomy for genu valgum performed three and a half years previously. The femur shows no trace of bony thickening at site of operation. The boy was aged eight years.

FIG. 4.



Skiagram of the femur of a boy, aged six years, in whom a fracture of the middle of the shaft occurred when he was two years old. No trace whatever of injury remains.

The Lumleian Lectures

ON

SOME DISORDERS OF THE SPLEEN.

Delivered before the Royal College of Physicians of London on March 17th, 22nd, and 24th,

By FREDERICK TAYLOR, M.D.,
F.R.C.P. Lond.,
SENIOR PHYSICIAN TO, AND LECTURER ON MEDICINE AT, GUY'S HOSPITAL.

LECTURE II.[1]

Delivered on March 22nd.

Mr. President and Gentlemen,—At the last lecture I was recording some cases of enlarged spleen in which the diagnosis had presented difficulties and I concluded with the remark that the recognition of the cause of enlargement depends less on the characters of the organ itself than on the associated conditions—except in respect of its size. I propose now to say something of the condition known as splenic anæmia, but before doing so must refer again to those cases in which a splenic enlargement may exist with comparatively good health and without an entirely satisfactory explanation of its occurrence.

Case 14.—The patient was a woman whose age was unrecorded. She had had pleuritic effusion, was tapped, and then became anæmic. Her periods were irregular and scanty. She had had influenza six months previously. A hæmic murmur could be heard at the base. The liver could not be felt. The spleen was two inches below the ribs. On a blood count being made the red corpuscles were 40 per cent. and the hæmoglobin was 20 per cent. Two weeks later the red corpuscles were 39 per cent., the hæmoglobin was from 15 to 20 per cent., and the leucocytes were 7000 per cubic millimetre. She was treated as a case of chlorosis. Nine days later the red corpuscles were 53 per cent., the hæmoglobin was 40 per cent., and the leucocytes numbered 7700 per cubic millimetre. 13 days later the red corpuscles were 80 per cent., the hæmoglobin was 50 per cent., and the leucocytes were 8000 per cubic millimetre. A week after this she went out looking very much better. This was apparently a case of chlorosis, but the enlargement of the spleen, which after all was slight, is unexplained. It is an interesting fact that the spleen is not commonly enlarged in chlorosis. Now, four years later we understand that she recovered sufficiently to become a hospital nurse, but her present condition is unknown.

Case 15.—A patient, aged 33 years, was seen by me in 1900. He had had influenza 15 months previously and another attack recently. Ten days previously there were sleeplessness, cough, anorexia, and a slight rise of temperature. Great enlargement of the liver was present. The spleen was within three inches of the middle line and three inches below the horizontal level of the umbilicus. A blood film showed normal red corpuscles and no excess of leucocytes. Two months later he was better and had been at work for three weeks. He thought himself quite well. The spleen was larger than it previously was. The red corpuscles numbered 5,000,000 per cubic millimetre and the hæmoglobin was 90 per cent. A leucocyte count was doubtful, but a film showed absolutely no excess, mainly small uninuclears with a few polymorphonuclears; no myelocytes were present. Recently after an interval of three years the patient was in almost exactly the same condition. He was at work, called himself well, but was probably not really vigorous. The liver reached four and a half inches below the ribs. The spleen was only two inches from the middle line and five inches below the level of the umbilicus; vertically it extended fully ten inches. It felt rough on the surface; it was not very firm or hard and gave the impression that it could be bent transversely; it was painless and not tender. The red corpuscles numbered 4,600,000 and the leucocytes 8000 per cubic millimetre; the hæmoglobin was 85 per cent. The heart and the urine were normal. This is a difficult case to classify. The patient was born in London and had never had ague. He had not any valvular disease or cirrhosis, and though his liver is enlarged it is distinctly not hard and it is clinically quite unlike a cirrhotic liver. He had not pernicious anæmia or Hodgkin's disease, and there is no pigmentation or hæmorrhage. Is it possible that this will ultimately develop into splenic anæmia, that he will lose more and more hæmoglobin and corpuscles?

Splenic Anæmia.

We may take as our guide the criteria last formulated by Dr. H. D. Rolleston—viz., (1) splenic enlargement; (2) no enlargement of glands; (3) anæmia of chlorotic type; (4) leucopenia; (5) a long course; and (6) tendency to hæmorrhage, especially of the gastro-intestinal tract; to which Professor W. Osler would add, (7) pigmentation of the skin; and (8) secondary enlargement of the liver. As I said in my last lecture, the criteria of splenic anæmia have varied somewhat. I may here record some cases which may claim to be regarded as instances of this disease.

Case 16.—A medical man, aged about 50 years, came under my notice in March, 1894. He had been ill since the preceding November, when he was taken with dizziness and pyrexia, but though his more serious troubles began at this time he was conscious of something wrong with the left hypochondrium as long as two years before that (1891). He had been taking arsenic for some weeks and had noticed the following changes in his condition: (1) darkening of the skin and a curiously hyperæsthetic condition, so that a slight knock would be felt as pain; (2) the eyes were irritable; (3) the legs were weaker; and (4) he thought that the spleen was smaller. He was a medium-sized, thin-faced man, the face apparently tanned by exposure, but at the same time obviously anæmic, as were the lips and the mucous membranes. The hands were thin, tanned, almost emaciated, anæmic at the nails, and the ends were not obviously thickened. In the palms a whitening of the natural furrows, with perhaps a little redness of the intervening skin, was present. The forearms were not very dark, nor were the upper arms; the trunk was covered with an unusually thick and dark crop of tinea versicolor so that the actual colour of the skin could not be seen through it. The heart was normal in position and sounds. The chest was flat, resonant, with normal expansion; here and there a fine râle could be heard, but there was no other suggestion of tubercle. The abdomen was full, tumid, especially on the left side, and the spleen and the liver were obviously enlarged The liver reached to within half an inch of the horizontal umbilicus level in expiration and descended to one inch below it in inspiration. It was firm but not hard; it had a smooth surface and a normally sharp edge. The spleen occupied the left flank and bulged the left anterior abdominal wall. During expiration it reached to half an inch below the umbilicus level and descended one and a half inches during inspiration. In the position of expiration the anterior edge was two and a quarter inches from the centre of the umbilicus; the lowest point was then two inches from the anterior superior spine and three and three-quarters from the costal margin vertically. The organs were not tender on pressure. A few posterior cervical glands could be felt but there were none in the axilla or groin. The urine was high coloured and deposited urates at once; there was no albumin; nitric acid produced a dark brown colouration. The feet were not swollen but the patient said that they became so sometimes. The inner border of the right tibia was thickened as if from periostitis. The blood from the finger showed no excess of leucocytes but a few tailed poikilocytes. The optic discs were rather hazy and pale; the edge was not well defined but was not blurred. Some veins were rather tortuous; there were no hæmorrhages. Two or three weeks later, on March 19th, he came into the private ward in Guy's Hospital. His weight was 9 stones 13 pounds. On the 21st his blood was found to have 3,000,000 red corpuscles per cubic millimetre and the hæmoglobin was 30 per cent. On the 29th the red corpuscles numbered 3,000,000 per cubic millimetre and the hæmoglobin was 35 per cent. On April 6th the red corpuscles numbered 4,250,000 and the hæmoglobin was 45 per cent. On the 13th he was certainly much better, less anæmic, fuller in the face, and had a good appetite. The red corpuscles numbered 3,800,000 per cubic millimetre and the hæmoglobin was 40 per cent. The spleen was only down to the level of the umbilicus on expiration, that is half an inch less in vertical movement than before. He had in the hospital oxygen inhalations and internally liquor arsenicalis and potassium iodide. He left shortly after—namely, on April 30th. On July 23rd I heard from him that he was much better. He had not been weighed. His colour was vastly improved. His feet and ankles were never œdematous. He was still taking arsenic. On May 20th, 1897, he wrote to me that his appetite was fairly good; that he could walk several miles, provided he walked slowly; that the spleen was not less in size, but certainly not much, if at all, larger; and that he was not *taking any medicine. He died in 1903. The duration of his* illness was therefore at least 12 years.

---

[1] Lecture I. was published in The Lancet of May 28th, 1904, p. 1477.

Of some cases recorded at the hospital we have the following.

CASE 17.—This was a very doubtful case and the clinical history is not forthcoming. There was a large, much infarcted spleen, weighing 91 ounces. There were subarachnoid hæmorrh, rhages of the right fr half of the cerebellum, petechiæ. *The blood was never examined; much anæmia* was present.

CASE 18.—A girl, aged ten years, was admitted for parotid swelling on Dec. 26th, 1897. She vomited blood frequently and then a lump was felt in the abdomen. She was very anæmic. Three weeks later the spleen reached below the umbilicus. A soft apical systolic murmur could be heard. The red corpuscles numbered 3,300,000 per cubic millimetre and the hæmoglobin was 30 per cent. Leucopenia was present. The liver was just perceptible. The retinæ were normal. *This is a case that was published by Dr. L. E.* Shaw in vol. lvi. of the Guy's Hospital Reports. Post mortem the spleen weighed 14 ounces and appeared to be normal in structure.

CASE 19.—The patient was a man, aged 28 years, who was admitted in 1900 under my care for general weakness and intermittent pyrexia. Nine months before he had had a bicycle accident. He thought that his side might have been injured. In January, 1900, he had shivering fits, headache, vomiting, and fever, and continued in varying condition. On admission the temperature was *103·4°* and the pulse was 120. He was very weak and had slight jaundice. His legs were wasted and his feet were œdematous. The red corpuscles numbered 850,000 per cubic millimetre and the hæmoglobin was 20 per cent. Leucopenia was present. The spleen reached one or two inches below the umbilicus. The liver could not be felt but the abdomen was very tender below the right costal margin. There were retinal hæmorrhages and increasing jaundice. Death ensued in a week. Post mortem the lungs were found to be emphysematous. *There were old adhesions. The bronchial glands were large.* The liver was large but not tough and weighed 2200 grammes (77 ounces); it appeared to be fatty. The spleen weighed 1334 grammes (47 ounces). There were small infarcts at the edges but no excess of lymphoid tissue. The kidneys weighed 406 grammes (13 ounces).

These were cases in which post-mortem examinations were held. The first, Dr. Shaw's case, must be admitted. The information about the others is too scanty. Of cases without post-mortem examinations we have five.

CASE 20 (1898, the late Dr. Washbourn).—The patient was a man, aged 26 years He stated that his abdomen was swollen as long as he could remember. A fortnight previously he had suffered from headache and cough and was feverish. He grew worse and epistaxis supervened. For the last few weeks he had been anæmic. On admission the liver was normal. The spleen reached right down to the iliac fossa and in the middle line below the umbilicus. The red corpuscles numbered 4,200,000 per cubic millimetre and the hæmoglobin was 47 per cent. There were a few leucocytes but no poikilocytes. A month later the red corpuscles numbered 4,300,000 per cubic millimetre and the hæmoglobin was 80 per cent The patient left the hospital.

CASE 21 (1899, Clinical Ward).—The patient was a boy, aged 12 years. He had had measles at the age of two and a half years; then diphtheria and severe epistaxis. He was always liable to hæmorrhages and epistaxis. He was very anæmic. There was slight enlargement of the inguinal glands. Apical and pulmonary systolic murmurs could be heard. The liver and the spleen reached to three inches below the ribs. The red corpuscles numbered 3,000,000 and the white corpuscles 10,700 per cubic millimetre. The hæmoglobin was 20 per cent. Epistaxis was frequent. The patient left the hospital.

This case seems less certain. *The tendency to bleed is* perhaps no more than a genuine mild hæmophilia. The spleen has as yet not reached a really great size.

CASE 22 (1900, Clinical Ward).—The patient was a woman, aged 44 years, who was admitted for wasting and swelling of the abdomen. She had had hæmoptysis two years previously. 18 months previously she had had acute enteritis, passing blood, and she had passed blood on other occasions since then. She was pale and thin. Her temperature was 100° F. The spleen reached down *to the crest of the ilium and within three inches of* the umbilicus. The liver was two or three inches below the costal margin. The red corpuscles numbered 4,000,000 and the white corpuscles 7000 per cubic millimetre and the hæmoglobin was 70 per cent. The organs were tender. There were some râles in the chest which soon disappeared. Diarrhœa was present. The patient left the hospital with the blood unaltered.

This case appears to present all the characteristics except the long duration.

CASE 23 (1901, Dr. W. Hale White).—The patient was a male, aged 39 years. He had had pleurisy nine years and mumps six years previously. His nose bled very readily. At Christmas, 1900, acute abdominal pain came on; a fortnight afterwards the pain became worse but he recovered after spending a time in bed. He then brought up dark blood into the mouth repeatedly. In June, 1901, he brought up a clot of blood. The spleen was found to be enlarged. On admission he was sallow but "not markedly anæmic." The liver could just be felt. The spleen reached nearly to *the middle line and as low as the level of the umbilicus*; it was rather tender. The red corpuscles numbered 3,400,000 per cubic millimetre and the hæmoglobin was 62 per cent. The leucocytes were normal. The temperature was irregular. Arsenic was given. He went out in a fortnight but died ten months later, having suffered from rheumatism, hæmorrhage three months before death, jaundice, and dropsy.

This case is uncertain. The spleen was moderately large and the other characteristics, except a very long duration, were present, but the termination would meet the case of *cirrhosis rather than Banti's disease, for which* the course is hardly long enough.

CASE 24. (1901, Clinical Ward.)—The patient was a female, aged 37 years. She stated that she had had fits at the age of 12 years. Three years before she had had an enlarged abdomen. She suffered from abdominal pains, morning vomiting, and diarrhœa, the motions at times being mingled with blood. The urine was said also to contain blood. Epistaxis was present. Rapid enlargement of the abdomen had occurred during the last two months. She was *anæmic and ascites* was present. The liver reached nearly down to the umbilicus. The anterior edge of the spleen reached to the umbilicus and the lower edge to the crest of the ilium. The red corpuscles numbered 4,800,000 and the white corpuscles 2500 per cubic millimetre. The hæmoglobin was 60 per cent. The patient left hospital with no material change in her condition. She had undoubtedly all the characteristics of splenic anæmia. Nothing more can be heard of her.

The next are two cases, brother and sister, who died in Guy's Hospital in 1902 under my care, but they had been frequently in other hospitals, especially in St. Thomas's; and I am indebted to Dr. T. D. Acland for permission to publish some of the facts, which were kindly abstracted for me by Dr. A. E Russell.

CASE 25.—The sister was in St. Thomas's Hospital in 1897 with anæmia. The edges of the spleen and the liver were palpable. Previously she had had diarrhœa and abdominal pain with slight irregular fever. The red corpuscles numbered 2,240,000 per cubic millimetre. In 1900 she was again in St. Thomas's Hospital. Then her skin was yellowish. The spleen reached nearly down to the level of the umbilicus and the liver to one inch below the ribs. There were no enlarged glands. The red cells numbered 2.746,000 per cubic millimetre and the hæmoglobin was 65 per cent. The number of the leucocytes was not recorded. The polymorphonuclears were in normal proportion. The myelocytes were 2·5 per cent. Two years later, at the age of 10 years, she came into Guy's Hospital. Five days before admission vomiting set in. Now she was collapsed and restless and occasionally she screamed. Her skin was of a brownish-yellow colour, not the yellow of jaundice nor the lemon-yellow of pernicious anæmia, but rather bistre. The spleen was two inches

The Lumleian Lectures

ON

SOME DISORDERS OF THE SPLEEN.

Delivered before the Royal College of Physicians of London on March 17th, 22nd, and 24th,

By FREDERICK TAYLOR, M.D.,
F.R.C.P. Lond.,
SENIOR PHYSICIAN TO, AND LECTURER ON MEDICINE AT, GUY'S HOSPITAL.

LECTURE II.[1]

Delivered on March 22nd.

Mr. President and Gentlemen,—At the last lecture I was recording some cases of enlarged spleen in which the diagnosis had presented difficulties and I concluded with the remark that the recognition of the cause of enlargement depends less on the characters of the organ itself than on the associated conditions—except in respect of its size. I propose now to say something of the condition known as splenic anæmia, but before doing so must refer again to those cases in which a splenic enlargement may exist with comparatively good health and without an entirely satisfactory explanation of its occurrence.

Case 14.—The patient was a woman whose age was unrecorded. She had had pleuritic effusion, was tapped, and then became anæmic. Her periods were irregular and scanty. She had had influenza six months previously. A hæmic murmur could be heard at the base. The liver could not be felt. The spleen was two inches below the ribs. On a blood count being made the red corpuscles were 40 per cent. and the hæmoglobin was 20 per cent. Two weeks later the red corpuscles were 39 per cent., the hæmoglobin was from 15 to 20 per cent., and the leucocytes were 7000 per cubic millimetre. She was treated as a case of chlorosis. Nine days later the red corpuscles were 53 per cent., the hæmoglobin was 40 per cent., and the leucocytes numbered 7700 per cubic millimetre. 13 days later the red corpuscles were 80 per cent., the hæmoglobin was 50 per cent., and the leucocytes were 8000 per cubic millimetre. A week after this she went out looking very much better. This was apparently a case of chlorosis, but the enlargement of the spleen, which after all was slight, is unexplained. It is an interesting fact that the spleen is not commonly enlarged in chlorosis. Now, four years later we understand that she recovered sufficiently to become a hospital nurse, but her present condition is unknown.

Case 15.—A patient, aged 33 years, was seen by me in 1900. He had had influenza 15 months previously and another attack recently. Ten days previously there were sleeplessness, cough, anorexia, and a slight rise of temperature. Great enlargement of the liver was present. The spleen was within three inches of the middle line and three inches below the horizontal level of the umbilicus. A blood film showed normal red corpuscles and no excess of leucocytes. Two months later he was better and had been at work for three weeks. He thought himself quite well. The spleen was larger than it previously was. The red corpuscles numbered 5,000,000 per cubic millimetre and the hæmoglobin was 90 per cent. A leucocyte count was doubtful, but a film showed absolutely no excess, mainly small uninuclears with a few polymorphonuclears; no myelocytes were present. Recently after an interval of three years the patient was in almost exactly the same condition. He was at work, called himself well, but was probably not really vigorous. The liver reached four and a half inches below the ribs. The spleen was only two inches from the middle line and five inches below the level of the umbilicus; vertically it extended fully ten inches. It felt rough on the surface; it was not very firm or hard and gave the impression that it could be bent transversely; it was painless and not tender. The red corpuscles numbered 4,600,000 and the leucocytes 8000 per cubic millimetre; the hæmoglobin was 85 per cent. The heart and the urine were normal. This is a difficult case to classify. The patient was born in London and had never had ague. He had not any valvular disease or cirrhosis, and though his liver is enlarged it is distinctly not hard and it is clinically quite unlike a cirrhotic liver. He had not pernicious anæmia or Hodgkin's disease, and there is no pigmentation or hæmorrhage. Is it possible that this will ultimately develop into splenic anæmia, that he will lose more and more hæmoglobin and corpuscles?

Splenic Anæmia.

We may take as our guide the criteria last formulated by Dr. H. D. Rolleston—viz., (1) splenic enlargement; (2) no enlargement of glands; (3) anæmia of chlorotic type; (4) leucopenia; (5) a long course; and (6) tendency to hæmorrhage, especially of the gastro-intestinal tract; to which Professor W. Osler would add, (7) pigmentation of the skin; and (8) secondary enlargement of the liver. As I said in my last lecture, the criteria of splenic anæmia have varied somewhat. I may here record some cases which may claim to be regarded as instances of this disease.

Case 16.—A medical man, aged about 50 years, came under my notice in March, 1894. He had been ill since the preceding November, when he was taken with dizziness and pyrexia, but though his more serious troubles began at this time he was conscious of something wrong with the left hypochondrium as long as two years before that (1891). He had been taking arsenic for some weeks and had noticed the following changes in his condition: (1) darkening of the skin and a curiously hyperæsthetic condition, so that a slight knock would be felt as pain; (2) the eyes were irritable; (3) the legs were weaker; and (4) he thought that the spleen was smaller. He was a medium-sized, thin-faced man, the face apparently tanned by exposure, but at the same time obviously anæmic, as were the lips and the mucous membranes. The hands were thin, tanned, almost emaciated, anæmic at the nails, and the ends were not obviously thickened. In the palms a whitening of the natural furrows, with perhaps a little redness of the intervening skin, was present. The forearms were not very dark, nor were the upper arms; the trunk was covered with an unusually thick and dark crop of tinea versicolor so that the actual colour of the skin could not be seen through it. The heart was normal in position and sounds. The chest was flat, resonant, with normal expansion; here and there a fine râle could be heard, but there was no other suggestion of tubercle. The abdomen was full, tumid, especially on the left side, and the spleen and the liver were obviously enlarged The liver reached to within half an inch of the horizontal umbilicus level in expiration and descended to one inch below it in inspiration. It was firm but not hard; it had a smooth surface and a normally sharp edge. The spleen occupied the left flank and bulged the left anterior abdominal wall. During expiration it reached to half an inch below the umbilicus level and descended one and a half inches during inspiration. In the position of expiration the anterior edge was two and a quarter inches from the centre of the umbilicus; the lowest point was then two inches from the anterior superior spine and three and three-quarters from the costal margin vertically. The organs were not tender on pressure. A few posterior cervical glands could be felt but there were none in the axilla or groin. The urine was high coloured and deposited urates at once; there was no albumin; nitric acid produced a dark brown colouration. The feet were not swollen but the patient said that they became so sometimes. The inner border of the right tibia was thickened as if from periostitis. The blood from the finger showed no excess of leucocytes but a few tailed poikilocytes. The optic discs were rather hazy and pale; the edge was not well defined but was not blurred. Some veins were rather tortuous; there were no hæmorrhages. Two or three weeks later, on March 19th, he came into the private ward in Guy's Hospital. His weight was 9 stones 13 pounds. On the 21st his blood was found to have 3,000,000 red corpuscles per cubic millimetre and the hæmoglobin was 30 per cent. On the 29th the red corpuscles numbered 3,000,000 per cubic millimetre and the hæmoglobin was 35 per cent. On April 6th the red corpuscles numbered 4,250,000 and the hæmoglobin was 45 per cent. On the 13th he was certainly much better, less anæmic, fuller in the face, and had a good appetite. The red corpuscles numbered 3,800,000 per cubic millimetre and the hæmoglobin was 40 per cent. The spleen was only down to the level of the umbilicus on expiration, that is half an inch less in vertical movement the intestine. It is easy to make the suggestion but difficult to substantiate it by proof; and this hiatus in the argument was noted by the President, Professor D. J. Hamilton, at the meeting when this subject was discussed. The subject is presented in too ethereal a form at present to make it possible to advance very strong arguments against it. But attention may be called to the number of diseases which have been explained by this hypothesis of an intestinal toxin—*auto-intoxication from the alimentary canal;* for instance, chlorosis (Sir Andrew Clark and others), anæmia (Bradshaw), cirrhosis of the liver (Potain), splenomegalic cirrhosis (French authors), tetany (many authors), pernicious anæmia (Hunter), Hodgkin's disease (Senator), splenic anæmia (Rolleston and others), anæmia splenica infantum (Rivière and others), the malaise of biliousness and constipation, and by some authors chorea and osteo arthritis.

---

[1] Lecture I. was published in The Lancet of May 28th, 1904, p. 1477.

3. *How does the enlargement of the spleen cause the anæmia?* This, again, presents difficulties which are met as far as I can see by no one. That it does so appears to be shown by the fact that the anæmia has been cured by removal of the spleen; but this fact may also be taken to show that the spleen is not really wanted for blood formation seeing that directly it is removed the blood is better formed than it was before.

Dr. Rolleston suggests as most probable that poisons produced in the spleen inhibit blood formation, and perhaps this is as far as we can go considering what is known of the formation of the blood. The question here is again, What determines the formation in the spleen of the hypothetical poisons? why do some persons go on for years, as in cases mentioned by Professor Osler and as in the case which I have referred to, with enlarged spleens which do not produce poisons to inhibit the formation of the blood? At any rate it appears to be clear that in ordinary cases the process is not one of hæmolysis; the blood is not destroyed by poisons found in the spleen. The condition of the blood is that of chlorosis and the numerous secondary anæmias, the colour index is less than 1, the hæmoglobin percentage is less than that of the red corpuscles, and as a rule hæmosiderin is not found in the viscera—that is, the liver does not give the Prussian blue reaction with potassium ferrocyanide and hydrochloric acid.

It is interesting to see the views entertained on the subject by that distinguished physician Professor Senator of Berlin, as he propounded them at the meeting of the British Medical Association. He seemed less inclined than the opener of the debate to limit the term to a particular form with the limiting criteria I have referred to, and especially appeared prepared to include under splenic anæmia conditions having a rather definite causation, such cause, however, acting rather as a disposing than a directly exciting cause. He instanced the case of spleens originally enlarged in the course of an infectious disease (typhoid fever or malaria) never completely subsiding and later becoming much enlarged; hereditary syphilis, rickets, and Barlow's disease (infantile scurvy) were also mentioned by him. But in addition to these are cases in which there is no preceding history to explain the occurrence, and in such cases he was in agreement with others in suggesting that injurious substances might reach the spleen by lymphatic channels from the intestinal tube. He recognised that the liver might be affected secondarily, but that ascites might occur without any cirrhotic change in the liver and possibly as a result of the blocking of the portal capillaries with transported large endothelial cells. An important statement of his is that severe anæmia only arises when the bone-marrow is involved by the occurrence in it of circumscribed lymphoid or lymphadenoid spots, myelomata. Another secondary result on which he lays some stress is a swelling of the abdominal lymphatic glands. His conclusions are that splenic anæmia is to be regarded as one form of pseudo-leukæmia, a pseudo-leukæmia lienalis. He thus links it to Hodgkin's disease, or pseudo-leukæmia lymphatica, and admits thirdly a pseudo-leukæmia myelogenica, when the bone-marrow is involved. These conditions, according to him, can be variously combined and, as already stated, he appears to think that his pseudo-leukæmia lienalis can only produce a severe anæmia when it comes into partnership with a pseudo-leukæmia myelogenica, and further, as a corollary to this, that when removal of the spleen has been successful it is because the bone-marrow has not at that time been involved.

The implication of the bone-marrow has been, of course, recorded by others. Rolleston refers to a case by Dr. W. Ewart in which the bone marrow was healthy—it may have been a matter of time relations; while he points out that Sippy, Williamson, and Michell Clarke have seen changes in the bone marrow. In my case (Case 26) the bone-marrow was affected, but this is one of two cases—brother and sister—which show some points of resemblance with pernicious anæmia, and a possible confusion of these two conditions has been suspected in other cases. To this question I may recur again later.

Two cases of splenic anæmia have been recently published by Dr. Dock and Dr. Warthin.[2] In the first—that of a man, aged 41 years, the illness dated back only one week from the first observation; the patient felt a pain in the side and discovered a swelling which proved to be a large spleen reaching one inch to the right of the umbilicus and two and a half inches below it. The skin was somewhat pale and sallow, and the visible mucous membranes were of fair colour. The blood count was as follows: red corpuscles 4,480,000 and leucocytes 5857 per cubic millimetre and hæmoglobin 75 per cent. Of three other counts made in two the red corpuscles were over 4,000,000 per cubic millimetre. A little over four months later the spleen was removed and the patient died four days afterwards. The second case was that of a woman, aged 53 years, who after various dysenteric attacks spreading over six years, had a moderate amount of anæmia, the spleen reaching to the middle line above the umbilicus and to the horizontal level of the umbilicus. The red corpuscles numbered 2,800,000 and the leucocytes 5857 per cubic millimetre, and the hæmoglobin was 60 per cent. of the normal. The abdomen was tapped and yielded 3800 cubic centimetres (less than seven pints). A few days later the red blood corpuscles numbered 4,266,666 and the leucocytes 7894 per cubic millimetre, and the hæmoglobin was 70 per cent. The diagnosis was admittedly difficult. Later a fibroid in the uterus justified a laparotomy and it was then found that the liver was cirrhotic. A month after this operation hæmatemesis occurred and the patient died.

In both cases there was a marked fibrous hyperplasia of the spleen with endothelial proliferation and diminution of the lymphoid tissue. In the first case there was an early stage of cirrhosis of the liver; in the second the greater part of the liver presented the picture of an atrophic cirrhosis. In both cases also there was calcification of the portal vein with stenosis, sclerosis of vessels, especially of the portal area, hyperplasia of hæmolymph nodes and bone-marrow, and new formation of lymphoid tissue in the retroperitoneal fat. Dr. Dock and Dr. Warthin attach much importance to the stenosis of the portal vein and expressly state as bearing on the questions that have been already discussed that "the changes in the spleens of the two cases do not represent any feature that could not be explained by a chronic passive congestion of marked degree." At any rate there "is a possibility that the clinical picture of splenic anæmia or Banti's disease may be caused by a stenosis of the portal vein due to old phlebitis and thrombosis and the resulting stenosis." Naturally they submit that the question cannot be answered by two cases, but their final remarks are that the two cases "may be taken as further evidence in favour of the view that the symptom-complex represents a group of varying pathological conditions, the splenic condition being secondary."

In reference to the question of the occurrence or absence of hæmolysis or blood destruction more than once referred to, Dr. Dock and Dr. Warthin assert that in both these cases there was extensive hæmolysis, as shown in the endothelial phagocytes of certain portions of the spleens and by the activity of phagocytosis in the hæmolymph glands and in the bone-marrow. But they say that "in spite of so great a hæmolysis no hæmosiderin is found outside of these glands (hæmolymph nodes) and the bone-marrow. Iron tests of liver, spleen, and kidneys do not show a trace of iron. The hæmolysis is, therefore, different from that occurring in pernicious anæmia."

BANTI'S DISEASE.

Banti's disease is the termination of splenic anæmia in cirrhosis of the liver, jaundice, and ascites. Too few of these cases have been collected to make one sure of their exact relations; and it seems desirable that the cases should be known from the first to justify their inclusion in this group. Out of Professor Osler's 15 cases[3] two, No. 5 and No. 18, seem to have been Banti's disease, and amongst his 38 cases of anæmia and enlarged spleen collected from members of the association possibly three others may have been of this nature. This seems to show that though Banti's disease may be a sequel of splenic anæmia it is not a frequent sequel and from these cases it is shown that splenic anæmia may last a very long time indeed without the secondary changes distinctive of Banti's disease being induced. Thus in his own list there are seven claiming a duration of ten years or more and of these only one (13 years) is certainly Banti's disease and a doubtful one is the longest case—viz., 15 years.

---

[2] American Journal of the Medical Sciences, January, 1904.

[3] Transactions of the Association of American Physicians, 1902.

I should like to refer here again to a case which I reported[4] under the name of splenomegalic cirrhosis and to which Professor Osler has alluded in his consideration of the conditions under which the spleen and the liver may be simultaneously enlarged, asking whether such cases may not come within the category of Banti's disease. It was the case of a boy admitted under my care at the age of 12 years with a history of having had scarlet fever three and a half years previously and of having become ill shortly after that, "He had pain in his left side and diarrhœa but no vomiting. Then his skin became yellow and jaundice was recognised." He had well-marked but not intense jaundice, a very large spleen reaching three inches across the middle line below the umbilicus and a moderately enlarged, hard, and slightly rough liver. He had at that time a red blood count 80 per cent. of the normal and shortly afterwards it was 84 per cent. He was of stunted growth and the skin was deeply pigmented. In the course of the next two and a half years his jaundice varied but became ultimately deep; the spleen became larger; the liver increased and was hard, rough, and obviously cirrhotic. Two months before his death the red corpuscles numbered 3,000,000 per cubic millimetre and six weeks only before his death he had ascites. I think it is difficult to assert that this case began as splenic anæmia and subsequently assumed the characters of Banti's disease. Though it is conceivable that he had anæmia before the date at which his illness is said to have commenced and even that his spleen was large then, still the available history is to the effect that jaundice was a very early symptom and practically that jaundice was present throughout, unless it disappeared temporarily at any time prior to his first admission, and if it did that is not a fact that assists particularly the diagnosis of splenic anæmia. Moreover, when first under me, three and a half years after the first symptom, he had no pronounced pallor and blood counts of 84 and 80 per cent., especially at that date, did not lend much support to a diagnosis of splenic anæmia.

It seems to me essential for the diagnosis of Banti's disease that the early history of the case should be known in respect of the blood. A case occurred at Guy's Hospital under Dr. G. Newton Pitt which bears upon this question. The patient was a man, aged 42 years. At about 20 years of age he had had dysentery in Egypt, also enteric fever and pneumonia, and then later some 12 attacks of ague. Five years later he was in the hospital with an enlarged liver and spleen, anæmia, and jaundice. Five years later again presumably at the age of 32 years, he was in again with a suppurating bubo and an enlarged liver and spleen. On the present occasion ascites was present; the spleen reached down to the level of the umbilicus. There were slight jaundice and increasing general œdema. Death ensued. The red blood corpuscles were 104 per cent., the hæmoglobin was 90 per cent., and the leucocytes numbered 4687 per cubic millimetre. The specific gravity was 1051. Post mortem the heart weighed 379 grammes (13 ounces). There was no obvious fatty change. The liver weighed 1554 grammes (55 ounces) and showed typical multilobular cirrhosis. The spleen weighed 1150 grammes (40½ ounces). A considerable fibrous change and a doubtful appearance of lardaceous change could be seen under the microscope; yet the splenic substance was pulpy and soft.

On the following day occurred the case of a boy, aged 14 years, who was admitted with a very large spleen, had cirrhosis of the liver and ascites, and was tapped several times, and died. Though we did not have at first a history of alcoholic indulgence his friends were detected in bringing him brandy and his father practically admitted that he was addicted to illicit drinking. Dr. H. S. French, who made the post-mortem examinations in these two cases, states that "the post-mortem appearances were remarkably alike in most respects."

If anæmia, cirrhosis, enlarged spleen, ascites, and jaundice can result from a cirrhosis primarily alcoholic, the proof that in a similar case the cirrhosis is secondary to a splenic anæmia must depend upon the early history showing a typical blood count and a much enlarged spleen before the liver is under suspicion of being gravely involved.

THE SPLEEN IN PERNICIOUS ANÆMIA.

The difficulties of the diagnosis of splenic anæmia from other cases of splenomegaly with anæmia present themselves in an interesting way in the case of pernicious anæmia. In most cases, as I have pointed out, it is the possibility that a splenomegaly with little or no anæmia may subsequently present the typical features of splenic anæmia which leaves us in doubt, and again the possibility that some lesion sufficient in itself to cause both the enlarged spleen and the anæmia may for a time be concealed from us. But as the disease progresses (which is not the same thing as saying "as time goes on") the diagnostic features are likely to become clearer, though the diagnosis between splenic anæmia and pernicious anæmia may require careful sifting even up to much later stages. From his first series of cases of splenic anæmia Professor Osler subsequently excluded one case as more likely to be pernicious anæmia.

As instances of the same difficulty I may refer again to the brother and sister whose cases I have already considered under the head of "Splenic Anæmia." To begin with, I think one must assume that whatever their disease was it was the same in both. The points in which they resembled pernicious anæmia were that in both there was a high degree of oligocythæmia (the boy 1,066,667 and 1,000,000 and the girl 1,300,000 per cubic millimetre). But this was only a few days before death and in their previous residence at St. Thomas's Hospital the red count varied from 2,000,000 to 3,000,000 per cubic millimetre. In the boy the colour index was far above unity; this also was when he was near his end. A few poikilocytes were noted in the girl's blood and a slight leucocytosis in that of the boy. After death the girl's liver and kidney gave a blue colour with potassium ferrocyanide and hydrochloric acid, "but not of deep enough tint to be called Prussian blue." The liver of the boy gave only a partial blue stain with the same reagents. In both the cardiac muscle was fattily degenerated. The bone-marrow in the femur, sternum, and ribs was dark red or maroon in colour. On the other side are these facts—that the cases affected two members of one family, an occurrence which has been more often recorded in connexion with those still obscure anæmic splenomegalies than with pernicious anæmia, and that the disease began in early childhood. Pernicious anæmia is well known to commence chiefly in adult life. Coupland says that cases are on record in patients as young as seven, 11, and 12 years. In my two cases the children were respectively four and six years when they were first under hospital treatment. The spleen in the girl, who was ten years of age at the time of her death, was two inches below the costal margin. Five years previously, when first seen, "the edges of both liver and spleen were palpable." That the spleen should have enlarged so little in the course of five years is, I must allow, a point rather unfavourable to the inclusion of the case under splenic anæmia. The spleen of the boy, who was 12 years of age at the time of death, was one and a half inches below the level of the umbilicus, an extent compatible with splenic anæmia, but unusual in pernicious anæmia. In 1894, when he was four years old, it was two inches below the costal margin. Five months later it was much larger and reached below the level of the umbilicus and this position of the organ seems to have been maintained, perhaps with slight increase, until the age of six years, when the *last record* is available prior to his admission to Guy's Hospital. This boy in the first two years of his illness was often described as being of a lemon-yellow tint; but in their last days both children had a pronounced pigmentation of the skin which presented what I described as a *bistre*—that is, a pale yellowish-brown colour, very like the earliest discolouration seen in Addison's disease. This is to my mind rather a characteristic of splenic anæmia than of pernicious anæmia.

As to the size of the spleen in pernicious anæmia Coupland says[5]: "The spleen may be slightly enlarged but often it is quite small; in colour and consistence it varies, being often pale, sometimes soft, or again rather indurated." Dr. W. Hunter has collected for his work on "Pernicious Anæmia" the results as to the condition of the spleen from several writers. He gives the normal weight as 225 grammes, or nearly eight ounces, and he says "in the great majority of cases, however, the spleen is described as normal or no mention is made of it." He alludes to three published cases in which it was 10, 16, and 19½ ounces respectively, and from Dr. Pye-Smith's list of 26 cases in which the size of the spleen is given 17 showed some increase—either expressed as "slightly enlarged," "somewhat enlarged," or as a weight in excess of eight ounces.[6] In four cases coming under his own observation Dr. Hunter found the spleen to weigh 19, 11, 10, and 13 ounces respectively. He has found it described as soft and diffluent, pale and soft, soft, or firm and red, firm, or of deep purple colour. Microscopically nothing specific has been described: a simple hyperplasia. In cases under his own observation the spleen has been soft and pulpy, of an extremely deep violet or purplish colour, contrasting in this respect very markedly with the pallor presented by all the other organs in the body. The iron-contents in seven cases examined by him were not in excess of what may be met with in certain other conditions. Dr. Hunter looks elsewhere than to the spleen for a means of diagnosing "pernicious anæmia" proper—viz., to the evidences of hæmolysis and the evidences of infection of which he finds practically always an example in an infective glossitis.

[5] Allbutt's System of Medicine, vol. v., p. 530.

I have recently had under my care a case of pernicious anæmia in which the spleen in a large fat woman was three inches below the left costal margin and the liver was about the same distance below the right. Unfortunately the record of the weight after death is not forthcoming; the colour index of the blood was 1·5 and the liver and kidneys contained an excess of free iron.

A CASE OF ACUTE HÆMORRHAGIC PANCREATITIS.

BY E. T. FISON, M.D. CANTAB., F.R.C.S. EDIN.,

PHYSICIAN TO SALISBURY INFIRMARY.

(*The Surgical Notes by* L. S. LUCKHAM, M.R.C.S. ENG., *Surgeon to Salisbury Infirmary.*)

ON account of the prominence given to inflammation and other diseases of the pancreas by Mr. A. W. Mayo Robson, and especially so in his most excellent Hunterian lectures,[1] I have thought it desirable to publish notes on the following ca

P. Blackmore, who advised the removal of the case has very kindly given me the following history ent's condition previously to my seeing him. a man, a wine merchant's traveller, aged 39 ose history was unimportant except for the fact out a year previously he had, he said, suffered n attack of "congestion of the liver." It was ed that he had not been greatly addicted to alcohol. March 26th, 1904, the bowels were confined but on e next day he had a sharp attack of diarrhœa; on the 28th, about one and a half hours after dinner, he was seized with severe epigastric pain and vomiting. Dr. Blackmore saw him at 5 P.M.; he was then vomiting frequently and complained of severe pain in the epigastrium. He had an anxious expression and looked very ill. Jaundice was absent. The abdomen was rather tense and tympanitic. There was considerable tenderness over the region of the gall-bladder and to a less degree over the stomach. There was no enlargement of the liver or indication of tumour elsewhere. His temperature was 98° F. and the pulse was 110, small, and feeble. On the 29th it was ascertained that the vomiting had continued frequently through the night and that he did not sleep. He still complained of pain in the epigastrium but said that he felt better. His temperature was 97° and the pulse was 120. The bowels had not acted and the amount of urine passed was very small in quantity, dark coloured, and loaded with lithates and bile pigment. On the 30th, under small doses of morphine, he had a more quiet night but the bowels had not acted and the vomiting still continued. His abdomen was more distended and the temperature was 96·8°, the pulse being 125, small, weak, and thready. Dr. Blackmore urged his removal to hospital for relief of what seemed to be obstruction of the bowels.

I saw the patient about one hour after admission to the Salisbury Infirmary. He said that he had been vomiting incessantly since an attack of pain in the pit of the stomach four days before and that his bowels had not acted nor had he passed any flatus; he said, however, that the pain was much less. He was a stout, well-nourished man but with a face of extreme anxiety—in fact, an abdominal face. His tongue was coated with a thick brown fur. The pulse was 120, very thin, and of low tension; the temperature was 97·4°; and the respirations were 36. The abdomen was distended and held rigid but moved fairly well with respiration. On palpation it was somewhat rigid and there was some tenderness in the epigastric region. No local resistance or signs of tumour were made out, the liver dulness was much diminished but was present, the hernial rings were normal, and there were no signs of fluid in the flanks. Auscultation of the chest revealed no basal pleurisy. Two enemata were given (one by a long tube) but both were returned uncoloured by fæcal matter. The patient passed about seven ounces of highly coloured urine in which there was no sugar but a trace of albumin. Inasmuch as the vomiting continued and the pulse was becoming worse, after consultation with my colleague Mr. Luckham it was thought advisable to perform laparotomy and to attempt to relieve what appeared to be obstruction, rather by band or internal hernia high in the intestinal canal.

Before operation the patient was given one-quarter of a grain of morphine and the stomach was washed out. Chloroform was employed and a median incision above the umbilicus was made. As soon as the skin was divided the fat of the abdominal wall was seen to be dotted with opaque yellow areas which at once suggested the condition termed "fat necrosis." The peritoneum being opened a very large quantity of inoffensive and brown fluid welled out; there was no free gas. Inspection of the great omentum revealed the same condition of fat necrosis and on this being turned up with the transverse colon, at the base of the transverse mesocolon and extending across the back of the abdomen an elongated swelling was felt which was made out to be the pancreas and the swollen tissues over it. This mass was dark in colour from hæmorrhage. The peritoneum itself showed only signs of early inflammation, there being no lymph, only injection of vessels. Three incisions were made into the tissues over the pancreas through the transverse mesocolon from which there was no bleeding. The gall-bladder was next inspected and was felt to be full of stones. The median incision was sewn up and drained with a large tube and gauze strips. A fresh incision was made in the right semilunar line, the gall-bladder was opened, and many stones and much grit were removed. A drainage-tube was tied in the gall-bladder, as it was impossible to bring it up to the abdominal wall, it being much contracted, a gauze drain was put in, and the wound was sewn up During the greater part of the time taken up by the operation the pulse at the wrist was barely discernible. On sensibility returning vomiting at once recommenced in which there was much bile. This vomiting, which latterly contained blood, continued without ceasing till death occurred. The patient was fed per rectum but failed to retain the enemata. Calomel by the mouth and turpentine enemata failed to act on the bowels. The amount of urine excreted was very small, about 11 ounces since the operation, which was drawn off by catheter on two occasions. He complained much of thirst but vomited all that was given by the mouth; he was therefore transfused. His temperature remained subnormal, having never been up to the normal line since the onset of his attack. He gradually lapsed into a state of toxæmia with increasing restlessness and died exactly five days after the initial symptoms.

I made a post-mortem examination on the next day. There was no change of importance in the chest except that the left pleural cavity contained about half a pint of sanious fluid and on the upper surface of the diaphragm were a few spots of fat necrosis. The condition of the abdomen was as follows. It was distended and tympanitic and on opening it the great omentum was found to be loosely adherent to the abdominal wall. On turning this up with the transverse colon and its mesocolon a very large swelling was felt in the situation of the pancreas. The operation incisions were visible in the base of the mesocolon. There was only about a pint of bloody fluid in the peritoneal

to a bulging in the right ventricle at the base of the tricuspid valve, one flap of which was directly infected. There were a few vegetations on the mitral valve, spreading from the aortic valve. At the bifurcation of the right popliteal artery was a massive embolus, resembling the cardiac vegetations, riding the angle formed by the branching of the artery and surrounded by recent thrombosis which completely occluded the lumen of both vessels. The spleen weighed 20 ounces; there were infarcts of various sizes and ages, none of which were softened. The organ was placed high in the abdominal cavity, being well supported by an unusually complete costo-splenic ligament, which formed a shelf upon which the spleen rested. This explained the fact that the enlarged spleen was not felt during life. The kidneys weighed 20 ounces together; there were a few small recent infarcts.

A bacteriological examination resulted as follows. Films from the vegetations and from the popliteal clot showed numerous pneumococci. Cultures from the vegetations, the heart's blood, and the spleen all gave good growths of pneumococcus. In cultures from the vegetations there were a few colonies of some post-mortem contamination. In all cases the pneumococci showed capsules staining well with carbol-fuchsin. No other organism was found in the cultures. Pathogenicity: a 24-hours broth culture from a colony on agar (heart's blood) killed a mouse in less than 24 hours. Pneumococci were recovered from the peritoneal exudate and from the heart's blood and were cultivated.

APPENDICITIS.[1]

BY RUSSELL COOMBE, M.A., M.D. CANTAB., F.R.C.S. ENG.,

SURGEON TO THE EXETER DISPENSARY AND TO THE EXETER LYING-IN CHARITY; CONSULTING SURGEON TO THE DEVON AND EXETER DENTAL HOSPITAL.

THE great frequency with which during recent years we are called upon to deal with cases of inflammation of the vermiform appendix and the extreme gravity of many of these cases have forced this subject to the very forefront and relieve me from any necessity for an apology in introducing it to you as a subject for discussion. I propose, therefore, to bring before you certain headings, shortly to run over the more recent work in each direction, to formulate any conclusions I have myself arrived at, and to ask the members of this society to express their own views on the points raised.

The headings I would suggest as most useful for discussion are the following: 1. What is the pathological lesion giving rise to an attack of "appendicitis"? 2. Is appendicitis more frequent than formerly? If so, to what is this increased frequency due? 3. What is the relative value of the various symptoms in appreciating the gravity of an attack of appendicitis and in the diagnosis of the disease; 4. When is it our duty to advise operative interference?

1. WHAT IS THE PATHOLOGICAL LESION GIVING RISE TO AN ATTACK OF "APPENDICITIS"?

Here at the outset we meet with divergent views. Treves[2] in the Cavendish lecture for 1902 says: "It is pure peritonitis; there is no consideration about it which is apart from peritonitis. Until the peritoneum is involved there is no malady." In support of his view he quotes a case of ovariotomy in which he came across "an appendix showing the grossest changes." This woman had never had any symptoms of appendicitis. On the other hand I can refer to two of my own cases in each of which a stenosed and dilated appendix lying free in the abdominal cavity and covered by healthy lustrous peritoneum gave rise to all the symptoms of appendicitis. In each case the removal of the appendix has relieved the patient completely of these symptoms. It is evident, therefore, that peritonitis is not a necessary item in the programme and that the view held by Treves cannot be accepted as an invariable rule. Charters Symonds[3] considers the rise of temperature is due to a septic process in the connective tissue of the appendix. Mansell Moullin[4] refers the pain and tenderness to the post-peritoneal connective tissue. Eccles[5] maintains that appendicitis is a bacterial inflammation of the appendix and that without such a form of inflammation no appendicitis can occur.

Thus besides the view that appendicitis is "pure peritonitis" we have here three different opinions to consider, and I believe that each of them is true from its own point of view. To take Eccles's view first, one can hardly doubt its accuracy. Concretions in the appendix have been found to be simply masses of bacteria; the sloughing of the sides of a wound made to evacuate an appendicular abscess and the fæcal odour so often observed (without the presence of a fæcal fistula) demonstrate clearly enough the bacterial origin of the disease. Then we can hardly believe that so fœtid an inflammation can occur without some inflammation of the neighbouring connective tissue and lymphatics and so we are prepared to accept Charters Symonds's and Mansell Moullin's views. The former has pointed out that the temperature often falls with the definite formation of an abscess; this quite agrees with our experiences elsewhere. The pain may have more than one source. We know that tension of viscera will cause most acute agony and it is doubtless the case that the severe pain of onset is often caused by tension, especially when a concretion is present; this in no way precludes the view that pain and tenderness arise in the post-peritoneal connective tissue; the severe pain of tension may indeed cease but the pain and tenderness of a cellulitis and lymphangitis may still be present.

I think we may safely conclude that appendicitis is a bacterial inflammation of the appendix, and that with stenosis of the organ the pain of tension may be severe; that tension may be so great as to cause perforation or gangrene, but that these may also result from the virulence of the poison; that in all but the mildest cases the connective tissue and lymphatics are inflamed; and that this inflammation is the cause of the pain and tenderness remaining after the acute pain of onset.

2. IS APPENDICITIS MORE FREQUENT THAN FORMERLY? IF SO, TO WHAT IS THIS INCREASED FREQUENCY DUE?

Treves[6] in his Cavendish lecture and Mayo Robson[7] in his Address in Surgery at Swansea both hold the view that the apparent increase is due to its more correct recognition. I find it frequently stated that this recognition is due to the work of Fitz of Boston in 1886, but it is quite clear that it was fully recognised long before this. Thus Mayo Robson[8] points out that perforative appendicitis and its consequences were well described by both Copland and Burne in 1837, and Wilks and Moxon[9] gave in 1875 a description of appendicitis to which an account of its bacteriology only needs to be added to bring it up to our present knowledge. It ought not to be difficult to ascertain the facts of the case. In the three years 1882-84 St. Batholomew's Hospital admitted an average of some 4000 patients annually. This had risen to some 6000 in the three years 1899-1901. In the former three years there were admitted 117 cases which might possibly be appendicitis—viz., 79 of perityphlitis and 38 of acute peritonitis. These 117 cases showed 23 deaths, of which six were proved post mortem to be due to causes other than appendicitis, leaving the statistics for those years as 111 cases with 17 deaths as the largest number of cases which could by any means be included as cases of appendicitis. Correcting the figures for the increased admissions there should be for the later three years 167 cases admitted, with 26 deaths. What do we actually find? That there were admitted in the later three years 321 cases of perityphlitis and appendicitis with 38 deaths. Moreover, 217 of these cases required operation and we may therefore fairly conclude that without such interference the deaths would (like admissions) have nearly doubled their proportion in the seven years' interval.[10] Barling,[11] quoting from the statistics of the Birmingham General Hospital, arrives at much the same results. The figures which I have shown are fairly convincing of a real increase in the frequency of the disease and if one's personal experience counts for anything it points strongly to the same conclusion. Thus an analysis of the cases for which I have been called to consultations in the surrounding country during the last ten years shows that the proportion of cases of appendicitis to all others has grown from $\frac{1}{5}$ per cent. to 10 per cent. during that period.

What, then, is the cause of this increased frequency? Let me remind you of its incidence: 80 per cent. of cases occur under 30 years of age; 73 per cent. of cases occur in males; therefore 60 per cent. of cases (nearly two-thirds) occur in males under 30 years of age. It has been stated that whatever its cause it must be one that affects all classes of the community, but I would point out that these figures suggest a cause especially affecting young males.

We may reflect that it is during the last 16 or 18 years that appendicitis has assumed its present importance and I believe that dental surgeons will uphold the view that the same period has shown the gravest deterioration in the fitness of the molar teeth for mastication. Admit this point and, further, remember that young men are especially the class who are prone to hurry their meals and often have to pick them up irregularly as best they may, and we shall see how other suggested causes become determining factors. Thus "a loaded cæcum" and tinned and frozen food come into play. Can a better nidus for bacterial development be imagined than a cæcum loaded with partially chewed, undigested masses which have been prepared for rapid decomposition by freezing or preservation for long periods?

3. WHAT IS THE RELATIVE VALUE OF THE VARIOUS SYMPTOMS IN APPRECIATING THE GRAVITY OF AN ATTACK OF APPENDICITIS AND IN THE DIAGNOSIS OF THE DISEASE?

We may here first make some simple classification of the degrees of the disease, remembering always that apparently mild cases may at any time develop serious symptoms: (1) Acute cases, separating diffuse and localised; (2) subacute; and (3) trifling or doubtful cases. We shall probably be called to our patient on account of an attack of abdominal pain; we shall note his appearance; inquire if there has been shivering, vomiting, or diarrhœa, and note his pulse, respiration, and temperature. Let us consider these points first.

Appearance of the patient.—I need not spend time in describing the appearance which constitutes the "abdominal facies." It should be familiar to all of us and I cannot lay too great stress on the importance of learning fully to estimate the value of a patient's appearance. It alone has frequently told me, and told me correctly at the first glance how great was the urgency of a case.

Shivering or a rigor.—Shivering is not uncommon; a definite rigor is a grave symptom and usually indicates a gangrenous appendix.

Vomiting.—This is not uncommon in acute cases; it is often absent in the ultra-acute. It is to be regarded as serious if it returns after an interval and becomes persistent and continuous; it is especially so if it persists in spite of feeding by the mouth having been discontinued.

Diarrhœa.—This usually indicates a severe attack and is looked on by some as indicating toxæmia; in any case it shows that peristalsis is going on and from that point of view is not unfavourable. Constipation is far more frequently present.

Pulse.—All are agreed that the pulse is of the utmost importance, though authorities differ as to whether its character or its rate is of the greater value. Personally I regard the latter symptom chiefly and a point on which I should like to lay the utmost stress is the importance of frequent records of its rate. If this is gradually falling from the rapidity caused by the onset of the attack there is time to wait; if it is remaining steadily above 100, and, still more, if it is increasing in rapidity, delay in operation is inadvisable. In my experience *a rising pulse with a falling temperature is an especially bad sign.* It must, however, be remembered that other symptoms besides the pulse may render interference necessary, for a pelvis full of pus has been found even with a pulse of 80.

Respiration.—It should be noted if this is costal in type. Its rate in relation to the pulse-rate should be carefully charted. This helps to distinguish thoracic disease in considering the diagnosis.

Temperature.—This is a factor of questionable value. It is almost always raised at the onset; I have already spoken of its falling whilst the pulse continues to rise. A too rapid fall to a subnormal temperature, especially if the patient shows any sign of drowsiness, is a bad sign and suggests a gangrenous appendix and increasing toxæmia. One must never forget that severe peritonitis may be present with a subnormal temperature. Such a temperature, with a rapid pulse, a fixed abdomen, no local tumour, and an abdominal facies, should arouse our gravest anxieties. If after falling steadily for a few days from the onset it begins to rise again, and especially if there be with this morning remissions, a localised abscess must be carefully watched for.

I have left the question of pain to the last, and as this will lead us to the examination of the abdomen I may enumerate the points which we have to investigate in this direction: (1) distension; (2) fixity; (3) rigidity; (4) pain; (5) superficial tenderness (hyperæsthesia); (6) deep tenderness; (7) tumour; (8) percussion results, including the presence or absence of peritoneal effusion; and (9) œdema of the abdominal wall. Perhaps I may here emphasise the necessity of having a thoroughly good light for inspection of the abdomen; care must be taken that the patient is lying perfectly level and for the purpose of palpation the knees must be well drawn up.

1. *Distension* implies arrest of peristalsis which in the early stages is reflex and indicates diffuse mischief; in the middle stages the arrest may have been produced by the exhibition of opium, a drug which, except for *one* dose to relieve the acute pain of the onset, is to be avoided most scrupulously in appendicitis; in the later stages the condition is due to decomposition of the intestinal contents and consequent paralytic distension. Peristalsis may be listened for with the stethoscope and measurements to estimate variations in distension should be taken and recorded.

2. *Fixity.*—This and the next symptom are of great importance; there should be no hurry in examination and the patient's attention should be diverted so far as possible.

---

[10] Cf. McDougall: THE LANCET, Feb 21st, 1903, p. 502.

[11] Brit. Med. Jour., Jan. 10th, 1903.

I have often found that a patient who will hardly move the abdomen with the observer's hand on the bare skin will move it freely when protected by the sheet or a thin warm towel. The costal type of respiration with abdominal fixation is of great diagnostic value, but even with a soft abdomen careful watching may show limitation of movement, the inspiratory act ceasing, possibly with a catch, before its full development.

3. *Rigidity.*—At the onset this may involve a considerable area of the abdomen; it should become more localised as the severe pain of the onset subsides. If it remains present over a large area it points to a considerable and diffuse peritonitis beneath. Thus I am accustomed to consider the non-formation within some 48 hours of the onset of "a lump" (be it local muscular rigidity or be it inflammatory matting) in a case not obviously of the subacute type as a grave sign and as indicating immediate interference. On the other hand, in some cases it is entirely absent; a perforated and gangrenous appendix has been found with quite soft abdominal muscles.

4. *Pain.*—It is a most important matter to have the patient's own story of the onset and to let him indicate the position in which he first felt pain. What is the cause of the pain in appendicitis? We know that the abdominal viscera are devoid of sensory nerves, as also is the visceral peritoneum. Inflammation of the parietal peritoneum or of the post-peritoneal cellular tissue and traction on the mesentery are the remaining sources of pain; the chief situations of pain in appendicitis are thus to be explained. Umbilical pain is due to peristalsis pulling on the mesentery. In operating under local anæsthesia traction on the root of the mesentery has been found to produce the same umbilical pain that arises from excessive peristalsis. Pain in the region of the appendix is usually referred to McBurney's point which, as I shall point out later, is the situation where the lymphatics of the appendix reach the post-peritoneal connective tissue. Moreover, should the appendix be in contact with the parietal peritoneum in any direction and communicate inflammation thereto, pain will also be felt in that situation. Thus I recently saw a lad, aged 17 years (the son of a medical man) in whom pain was most unusually severe at McBurney's point and was felt near the front of the abdomen. Twice in one night his father had to give morphine injections to allay this severe pain. Two days later I removed a sloughing and perforated appendix lying in contact with, and adherent to, the anterior abdominal wall.

5. *Superficial tenderness (hyperæsthesia).*—Head[12] and Mackenzie[13] independently first drew attention to this point in 1892, but little work has been done in the matter until recently. Mackenzie's explanation is that at certain spots small sensory nerve trunks approach the surface and thus are readily accessible to pressure. Head's view is that the stimulus required to call forth this cutaneous hyperæsthesia is that of tension. It is not, as in the case of pleurisy, due to direct irritation of the nerve trunks. In support of this he points out and teaches that it disappears on perforation or gangrene of the appendix. Since I have known of this symptom I have invariably looked for it and up to the present my observations have entirely confirmed Head's teaching. The method of searching for the symptom is by gently pinching or stroking the skin outside the suspected area and working round until the patch affected has been defined.

In appendicitis hyperæsthesia is found to affect chiefly the eleventh dorsal area mapped out by Head, encroaching on the two adjoining segments in severe cases and being limited to portions of the area in slighter cases. Sherren,[14] whilst registrar to the London Hospital, carefully investigated this symptom. Out of 81 cases operated on it was present in 19 and out of these perforation was only found in two cases, and in those two it had disappeared between the time of admission and the time of operation. In the remaining 62 cases it was absent on admission. In 23 of these cases perforation, and in 34 abscess, was found; whilst five were mild cases and were operated on after the subsidence of the attack. This symptom may be absent in secondary attacks but it is probably present at all times in primary attacks, except in fulminating cases and where an abscess has formed; its situation is not affected by the position of the appendix and it tends to pass off gradually with the subsidence of the attack; but should it disappear suddenly it points, as I have already stated, to perforation or gangrene of the appendix.

6. *Deep tenderness.*—It is obvious that we must distinguish early and late deep tenderness. The latter occurs in abscess cases and will vary with the situation of the abscess. Thus I saw a case recently in which this tenderness was just below the right costal margin, the pus having travelled up behind the colon. This abscess was opened and healed. It recurred abroad some months later and burst internally. I afterwards operated in a quiescent interval and found the patient to be the subject of an undescended cæcum. Early deep tenderness is associated with McBurney's point and much discussion has centred round the explanation of this symptom. McBurney's view was that this spot indicated the base of the appendix. It is obvious it could only indicate its base since the spot does not vary with the different positions assumed by the appendix. Eccles,[15] by the way, very well describes the most frequent of these as being respectively N., N.E., and S.E. At the request of Sir Frederick Treves[16] Dr. Keith made some investigations on this subject at the London Hospital. In 50 formalin-hardened bodies the base of the appendix was found to be almost invariably an inch *below McBurney's spot. What was found to correspond with* the spot was the ileo-cæcal valve. Moreover, in nearly all living subjects some tenderness can be found here. Thus, in 24 out of 27 medical students such a tender spot was found on the right side; in 11 it was exactly at the point, in nine a little above, and in four a little below. More recently as a result of Head's work the view has obtained that this being the point at which the mesentery of the appendix is attached to the posterior abdominal wall the tenderness to be found there in appendicitis is due to inflammation of the lymphatics of the appendix which run in its mesentery. In support of this view an interesting case is related in which it was present in a case of appendicitis in a patient the subject of non-descent of the cæcum. Here it could not have been referred to the base of the appendix or to the ileo-cæcal valve.

7. *Tumour.*—In later stages with a definite abscess there may be no question on this point. It is far otherwise in the earlier stages. Mackenzie[17] draws attention to the fact that where a tumour has been diagnosed by competent observers it has not unfrequently been undiscovered at an operation and he points out that Sherrington has demonstrated a peculiar power the flat abdominal muscles have of limited contraction. These muscles are supplied by more than one spinal nerve and if only one nerve root be stimulated limited contractions occur, whereas on stimulating a nerve (or one root of a nerve) going to a long muscle the whole muscle contracts. This phenomenon probably explains the so-called "phantom appendix" to which Treves[18] has specially called attention. Eccles[19] makes another suggestion—that it is the anterior longitudinal muscular band of the cæcum hardening under palpation. Personally I am convinced that local muscular rigidity is often taken for a tumour. In the early stages of an attack one often finds board-like muscles which absolutely defy palpation of underlying structures. It is only later, when rigidity has passed off, that a tumour can be felt through the muscles. More important than the formation of a tumour is its non-formation. It is precisely these cases in which no tumour appears within a short time of onset which give rise to the gravest anxiety and it is in these that immediate operative interference is most urgently indicated.

8. *Percussion.*—Battle[20] lays great stress on the presence or absence of peritoneal effusion and he recommends change of position to make the diagnosis sure. Barling[21] considers percussion of little value, pointing out that intestinal resonance may obscure a collection of fluid of some amount. Personally I have no great faith in percussion in such cases and I think the last thing in the world I should do would be to move the patient about unnecessarily from side to side and so risk the giving way of adhesions, the only result of which would be to allow foul fluid in the right flank to travel across to the opposite side. Moreover, in my experience such fluid, even when not limited by true adhesions, fortunately often has in front of it a zone of sticky peritoneum and therefore does not pass about spontaneously like a serous effusion in a lustrous peritoneum. We do not want to help it to do so.

9. *Œdema of the skin.*—This is a point that I have at times found helpful in determining the existence of underlying pus.

Having now completed our examination of the abdomen four points only remain for consideration.

1. *Examination of the rectum.*—This should never be omitted. It is especially required in women to distinguish pelvic inflammations.

2. *Leucocyte count.*—This has recently been shown to be of great importance and should never be omitted. During the first week, at least, it should be done daily; its advance or decrease will be of great assistance in those cases in which between the fourth and eighth day there are suggestions of the formation of an abscess. It is also useful later if there is anything to suggest the formation of a secondary abscess and it helps to distinguish appendicitis from other diseases. It is, however, no guide to the *amount* of pus present; thus a count of 17,000 has been found with a pint of pus and a count of 25,000 with only a couple of drachms. Variations[22] from normal to 62,500 have been observed. It may not appear in fulminating cases, where the resistance of the patient is too feeble to react to the toxæmia or where an abscess of some standing is well walled off. As one might expect, the largest counts are found in acute cases in robust young adults with strong reaction. In the lower counts—e.g., from 15,000 to 20,000—its advance or decline must be our guide. Personally, I have found this symptom of great service and even where an actual count has been impossible the altered proportion of leucocytes to erythrocytes is very apparent.

3. *Examination of the urine.*—This, a matter of routine in hospital work, should, if possible, not be omitted in private practice. I am aware that it may be difficult in emergencies at long distances, but the cases referred to by Mr. Rutherford Morison[23] serve to emphasise its importance. He reports six cases in which all the symptoms of acute abdominal illness have been present and the abdomen has been opened and no lesion revealed. The patients are usually at or past middle age and have "a curious, grey, apathetic look, with urine of low specific gravity, sometimes containing blood and albumin." A recognition of these cases has enabled him to avert operations on patients sent in for this purpose.

4. *Period of repose.*—We must always bear in mind when seeing an abdominal case within 24 hours of its onset that our first visit may be paid during the "period of repose" and that therefore the patient's life may entirely depend on at least a second, and if there is the least doubt perhaps several, visits at reasonably short intervals.

With the remainder of this part of the subject I do not propose to take long. It would be of little use to give a list of those conditions which have been mistaken for appendicitis or for which appendicitis has been mistaken. A careful investigation of the symptoms I have enumerated will, I believe, keep one from avoidable errors; thus the blood count will distinguish from typhoid fever and several other conditions; rectal examinations will distinguish diseases peculiar to women; the relation of pulse to respiration, if charted as I have suggested, will help to distinguish pneumonia and pleurisy; whilst the course of the temperature as well as other signs will be of use in distinguishing biliary or renal colic.

The fourth point I have to suggest for discussion is the question,

WHEN IS IT OUR DUTY TO ADVISE OPERATIVE INTERFERENCE?

Let us consider first the natural tendency and conditions of the disease. The tendency of an attack of appendicitis is to recovery, especially with suitable medical treatment. In my experience most of the cases seen in private practice require no surgical interference; but this does not hold good in hospital practice where only the more acute cases get sent in. The appendix, too, is in the majority of cases snugly tucked away in one corner of the abdomen under cover of the cæcum and it is a small organ from which no great leakage is likely to arise; thus there is usually time for adhesions to form. Further, we know that removal of the appendix during an attack is a proceeding leading to a high mortality, whilst its removal during a quiescent interval shows a low mortality. Thus we can at once decide not to advise operation in the acute stage simply with a view to removing the offending organ; there must be other and serious reasons for operating. To my mind three such reasons exist—(1) in acute cases, any ground for doubting if the peritoneal inflammation is localised; (2) a belief on our part that pus has formed; and (3) the existence of "peritonism." This last term [illegible] symptoms indicating a gra [illegible] cterised by pain, profound [illegible] pallor, a small soft quick [illegible] espiration, and vomiting. [illegible] by others, so it is well to be clear about its meaning in the present connexion.

It is when we have laid down our guiding rules and begin to apply them that our difficulties arise and the necessity for judgment comes into play. I have found the following points the most trustworthy guides:—

I. *In acute diffuse cases.*—1. The presence of symptoms of an abdominal catastrophe; in other words, the condition just described as "peritonism." In this connexion there are two points invariably to be borne in mind: (*a*) that we may be seeing the patient in the period of repose; and (*b*) that morphine may have been given. This point should never fail to be inquired into. 2. Increasing distension of the abdomen. 3. A large area of muscular rigidity and the failure of such rigidity to become localised. 4. The non-appearance of a localised swelling within 48 hours of the onset. 5. The continuance of the rapid pulse of onset for a dozen hours or more; still more a steady quickening of the pulse. 6. Evidence of peritoneal effusion, if obvious. 7. Disappearance of superficial tenderness without corresponding amelioration in the patient's symptoms. 8. Marked and increasing leucocytosis.

II. *In early abscess cases.*—1. Pulse beginning to rise again after first fall, especially if there be a steady quickening. 2. Temperature beginning to rise again after falling during the first three or four days, especially if the rises be in the evening with morning remissions. 3. A fairly defined tumour increasing steadily in size. 4. Œdema of the skin. 5. Leucocytosis, especially if increasing.

III. *In later abscess cases.*—A similar series of symptoms occurring at a later period would be my guides.

Finally, I prefer to be guided by the positive indications and to discount the possible absence of a symptom frequently present; above all things I take seriously a pulse rising steadily in rate and the absence of signs of localisation as shown by a "lump."

When should we advise operation in the quiescent stage? Saundby[24] says after the third attack; I think we shall all agree that this is not too soon. Mayo Robson[25] says: "I have no hesitation in saying that had I an attack of appendicitis I should prefer accepting the infinitesimal risk of removing the organ directly the attack was over to the decided risk of waiting to the next seizure which might be one of the acute type." Treves's view is that the whole matter is summed up in this question: "What is the probability of relapse?" At one time relapses occurred in from 20 to 30 per cent. of cases. There is little doubt that relapses are much more frequent now than formerly.

Seeing the low mortality resulting from operation in the quiescent interval the advice I have given to patients has agreed with the views of Treves and Robson rather than with those of Saundby and I have not had a case in which the appendix was in a condition to make me regret that I had opened the abdomen to remove it and I have seen cases which lead me to believe that the so-called "first attacks" have been preceded by what I have designated "trifling attacks." Two such cases are worth relating. One was a woman, aged 25 years, with a partially diffused attack. Her only previous history was that she did remember having two years previously had enough pain in the appendicular region to keep her in bed for a day. I say a partially diffused attack because in one direction an old adhesion was limiting pus in the peritoneum and binding the cæcum down; in other directions there was no such limitation and the pus was free; a five-inch long gangrenous and perforated appendix was removed, recovery ensuing. In the other case I operated in a quiescent interval after a so-called first attack which had, however, been, like the other case, preceded by a day's pain some time before. The appendix was stenosed, dilated, and full of muco-pus. It was firmly adherent to the posterior parietal peritoneum and these adhesions were certainly not from the recent attack. There were also considerable omental adhesions which were of the later date.

[26] Loc. cit.

One point that should especially indicate removal after a first attack is the liability of a patient to become pregnant. It has been found that when appendicitis has gone on to perforation or gangrene during pregnancy about 70 per cent.[27] of cases have been fatal both to mother and child. Abortion is usual and after the fourth month, when the uterus has risen out of the pelvis, it often forms part of the wall of the abscess cavity which ruptures as the uterus contracts, setting up diffuse and fatal peritonitis.

I hope I have not detained you too long: the subject is a large one and I have not been able to put before you innumerable points and considerations of great interest. That our meetings are necessarily limited in time must be my apology for the many omissions which must be apparent to you all.

Exeter.

SOME POINTS IN THE DIAGNOSIS OF APPENDICITIS.[1]

By W. BLAIR BELL, M.D. Lond., M.R.C.S. Eng.

On account of the very wide range which might be covered under this title I have confined myself to those points in the diagnosis of the various stages of appendicitis which have impressed me most from time to time and it is not my intention to touch upon such points as are very obvious and well known or to deal with the valuable recognition of leucocytosis, nor shall I undertake the detailed differentiation of the symptoms dependent on the variations in the direction of the appendix. In the first place, I should like to refer briefly to the condition known as

Appendicular colic.—The bare existence of this is by many denied; by others it is recognised, and rightly, I believe, to be the first indication that an appendix is liable to give future trouble, either because of the patency of its orifice or from the position which it occupies in relation to the cæcum. Unfortunately, attacks of appendicular colic do not often come under observation at the outset and evidence of them is only obtained by the surgeon at some future date when he is collecting the past history of a now obviously inflamed appendix. As I have seen this condition in *initial* attacks the following is a summary of what occurs. The patient, hitherto in perfect health perhaps, or slightly or markedly troubled with constipation, is suddenly seized with sharp pain commencing in the right iliac fossa. This pain lasts from half an hour to three hours and then rapidly disappears, leaving tenderness for from one to four days. Once the pain has subsided it is unusual for it to return if the patient is kept quietly in bed. The temperature is not raised but the pain may cause a slight increase in the pulse-rate. There is very little, if any, reflex muscular rigidity. It may perhaps be advisable to point out that a careful distinction must be made between reflex or *fixed* muscular rigidity—a rigidity which is noticeable on the patient taking a deep inspiration—and spasmodic rigidity which occurs on palpation. The former, as I have said, is absent in appendicular colic, whereas the latter—the spasmodic rigidity—is often marked. Appendicular colic may be distinguished from renal or biliary colic (1) by the history; (2) by the character of the pain, which though sharp is nothing like as severe as that produced by renal or biliary colic; and (3) by the ability of the patient in an initial attack of appendicular colic to localise the site of the pain. From intestinal colic it may be distinguished by the continuous nature of the pain in appendicular colic, by the fixed and recognisable position of it, and by the fact that pressure on the abdomen, which relieves intestinal colic, aggravates colic of appendicular origin. Appendicular colic, as I have found on several occasions, must also be distinguished from a colic of uterine origin which is seen in girls who for some reason, constitutional or local, have not menstruated regularly. If the possibility of this is borne in mind the differentiation is very simple.

Acute appendicitis, the next variety or stage to which I shall refer, covers such a wide field that I can do little more than tabulate the mistakes which I have seen made or have made myself. I find that the following conditions have come under my notice—either I or someone else having made a wrong diagnosis of appendicitis or *vice versâ*, or failed to recognise the condition at all: (1) intussusception; (2) ulceration and stenosis of Meckel's diverticulum; (3) tuberculosis of the ileum with abscess; (4) pyosalpinx; (5) tubal pregnancy; (6) perforated gastric ulcer; (7) liver abscess; and (8) no diagnosis considered possible. Formidable as this list seems, I fancy it could easily be trebled by those of wider experience than mine. Taking these collectively, I may say that each case had points of individual interest, but I propose to deal only with some of those of more or less general application.

First, if the patient is a woman on no account should one fail to exclude any possibility of right sided tubal or ovarian trouble. This may sound superfluous advice but I am sure that even with the greatest care mistakes are often made—in fact, it may not always be possible to avoid them—but I have myself seen or heard of so many errors where the patient is a female that I am certain we cannot be too cautious. Without saying more I may confess that it has been very strongly brought home to me on more than one occasion.

The second point of general application is the occurrence of cutaneous hyperæsthesia. It has been stated that this hyperæsthesia is, in appendicitis, limited to the areas of skin supplied by the eleventh dorsal nerve on the right side. Those who have studied this symptom also assert that the disappearance of it indicates in many cases gangrene or perforation. From my own observations I place great value on this symptom when it is present but it is by no means a constant one. The value is positive but never negative. Further, one must remember that if the peritoneal involvement is extensive the hyperæsthesia of the skin is not limited to the eleventh dorsal nerve but may invade the areas supplied by the tenth and even the ninth nerve on the right side. When present it is a very early sign and I have noted it before any muscular rigidity was found.

The third point concerns the localisation of the lesion when acute perforation of the appendix has taken place. I do not say the diagnosis of the actual lesion—for any severe lesion in the same region may give the same sign—but the localisation. This is a matter of some importance, for I think it commonly occurs, even with surgeons of the greatest skill, that before the lesion is found the abdomen has been explored in other directions than the right one and possibly through more opening than one, or even two. The first time that I was brought face to face with this difficulty was in the case of a patient who had been seized a few hours previously with the most violent abdominal pain; it was *general* and was accompanied by *general* rigidity. When I saw the patient she was much collapsed. A diagnosis of perforation of the stomach had been made by the medical man who first saw the patient, and indeed such might well have been the case if only the past history (as usual, of "gastritis") had been considered. The presence of liver dulness, with a few other signs of uncertain value, rather led me to a diagnosis of perforation of the appendix but I was by no means certain until I noticed that as anæsthesia progressed the muscle areas overlying the region of the appendix remained rigid after the rest of the abdominal wall had relaxed. Then at once I knew where to look for the lesion. Subsequent observations have proved to me the accuracy of this indication, so that I would lay it down as a law that *in general rigidity of the abdomen, consequent upon some acute lesion, the site of the lesion is situated beneath that area of muscular rigidity which is the latest to relax as anæsthesia progresses.*

My fourth and last point concerning acute appendicitis in a general way relates to the pulse, the temperature, and the disappearance of pain. By all means we must be guided in our reasonings by the pulse and temperature, but I think that we are inclined to forget that these can only be taken in conjunction with other signs, and that, although in an acute inflammatory condition we expect a high temperature and a rapid pulse, we may commit a grave error of judgment if we are able to recognise improvement only in a low temperature, a slow pulse, and the disappearance of pain, a state often indicative of gangrenous processes, septic peritonitis, and the beginning of the end—not of convalescence. A true appreciation of alterations of pulse rate and pulse character is one of the finest guides we have to the trend of nong which acute

---

[27] Eccles: loc. cit.

[1] Abstract of a paper read before the Liverpool Medical Institution.

[illegible] distinguished from relapsing or intermittent appendicitis. Strange though it may seem, the existence of a true chronic appendicitis is for the most part denied by both physicians and surgeons, each viewing the possibility of such a condition from opposite etiological standpoints. To me, however, it seems that this variety is becoming very common or at any rate can be frequently found if sought for. From its mode of origin, to be mentioned presently, it is obvious that it is found mostly among the wealthy classes and in the male sex. The patient usually complains of flatulence as the initial symptom, then pain, sometimes of a dull character, more often severe and griping, after food and it should be carefully noted that it usually comes on some time after food—i.e., from one to three hours. He is, too, a victim to constipation, from which, I take it, the bad dreams and "queer feelings" in the head arise of which he so often complains. The abdominal pain cannot always be accurately localised, either by the patient's own sensations or by palpation. As a rule the pain is located in the umbilical or hypogastric region. The pulse and temperature are found to be normal and the tongue clean but flabby. A thorough examination of the abdomen shows a slightly dilated stomach; if unwise, and how often is this the case, one will be tempted to be satisfied with that; but there is more, his colon is dilated, and more especially, or perhaps only, his cæcum. I have often seen a distinct bulging of the right iliac region from the dilated cæcum. This condition of alimentary dilatation is the result of good living, over-eating, and bolting indigestible food—habits spread probably over many years. It is, of course, perfectly possible for this condition to exist—indeed, it always does so at first—without any trouble in the appendix; but given a large flaccid cæcum, which is never properly emptied, septic to the last degree, and we can readily understand how frequently an appendix, prone by position or congenital structure, becomes involved. Were these cases to be recognised more frequently and to come under treatment in time they might be cured and the appendix be saved, but as a rule it is the infection of the appendix which prevents recovery and brings the case under treatment, an acute attack having perhaps supervened at last. From this it will be seen that I believe that a primary so-called "typhlitis" can exist, but while I recognise this fact I as truly recognise that it is of a slow and chronic nature, and that it cannot for long continue without infection of the appendix. Deaver in his comprehensive work on appendicitis says: "That the diagnosis (of appendicitis) is not always made is due to several causes, of which the most important are the persisting belief in a primary typhlitis, the non-appreciation of the frequency and seriousness of appendicitis, and the all too common habit of speaking ...... of 'inflammation of the bowels.'" Though most of that is only too true, yet in the blind warfare waged against the mention of "typhlitis" in relation to appendicitis the pendulum has been swung from one extreme to the other; acute appendicitis and its chronic relapsing form have alone been recognised, while the true chronic variety—probably the commonest of all—has escaped notice. It is true that acute appendicitis is not typhlitis, but it is, I believe, equally true that slow chronic dilatation of the cæcum with chronic typhlitis is the originating cause of what I term true chronic appendicitis.

Of the enormous differences of opinion which will always exist about the removal of the appendix in these cases I need not speak; let those hesitate to perform this necessary operation who will, so long as the condition is realised and the danger understood, so long as the patients are not treated for "gastritis," "liver," or "neurasthenia." To decide when the condition has passed from a simple cæcal complaint to an involvement of the appendix is, therefore, a matter of great importance. In endeavouring to decide this point the following considerations are worthy of notice. 1. Should the history be as I have related, but with exacerbations of the pain at intervals which may be attacks of true appendicular colic, such as I have mentioned above, or attacks of a more obscure nature accompanied or not by a raised temperature or vomiting—the pain being in the appendix region or elsewhere and possibly of a more fixed nature—then it is probable that the case will not recover until the appendix has been removed. 2. Any case of the type described above, which resists treatment by aperients, antiseptics such as salol, lavage, restricted and selected diet, and, above all, any case aggravated instead of improved by a course of abdominal massage, has some irritant cause as its basis: that cause is a chronic inflamed appendix. 3. The following signs, also, I have found useful in determining appendix infection. (a) Hyperæsthesia. This may be quite local and is generally one small spot on the outer edge of the rectus muscle—probably coincidental with McBurney's point. The sensitive area is below the skin but not in the abdomen, and light side-to-side pressure is required to find it, but it is rarely in the same place in two individuals. Sometimes, too, there is a cutaneous hyperæsthesia (which does not seem limited to the area of the eleventh dorsal nerve) and this is generally accidentally elicited by brushing against the individual or by the pressure of his trousers. (b) Reflex-pain sign, as I would term it. If the patient complains of pain in the neighbourhood of the umbilicus or hypogastrium it is found that pressure by palpation in those regions does not increase the pain, but that pressure over the appendix—not tender perhaps in itself—does increase this reflex pain elsewhere.

Certainty of diagnosis, and certainty therefore as to the benefit of operation in these chronic cases, is to be aimed at. There should be no room for operation "on spec." if I may so term it. Due care in the selection, which will be attended by successful results, is absolutely necessary. There need, in short, be no indiscriminate appendectomising of every victim to indigestion; at the same time there is a field, as I have endeavoured to show, for the successful treatment by operation of a class of case whose life is too often taken up visiting physician after physician in the hope of finding a cure for his indigestion. A word of warning is necessary: it must be remembered that in these cases the removal of the appendix must be followed by the treatment mentioned above to cure the dilated cæcum, else only a partially successful result will be obtained.

Liverpool.

REMOVAL OF THE SEMICIRCULAR CANALS IN A CASE OF UNILATERAL AURAL VERTIGO.[1]

By RICHARD LAKE, F.R.C.S. ENG.,
SURGEON, ROYAL EAR HOSPITAL, LONDON.

THE patient was a woman, aged 21 years, who had been the subject of attacks of aural vertigo, combined with sickness and vomiting, with gradually increasing deafness and tinnitus, the whole duration of the disease being five years. No cause could be found for the origin of the deafness. During this period she had been subjected to long courses of treatment, both by careful dieting and by the administration of various drugs of repute for the relief of these symptoms. I first saw her six months before the operation which I am about to describe was performed. As she stated that she thought the use of her eyes in reading and in needlework tended to induce the attacks she was examined at St. Thomas's Hospital by Mr. J. H. Fisher, who diagnosed slight hypertrophic astigmatism and ordered her appropriate glasses which she wore until a fortnight before the operation. She, however, stated that the use of these glasses made no difference as to the frequency of her attacks. The attacks were heralded in usually by increased tinnitus which not infrequently came on while she was lying down. The tinnitus persisted after the sickness and vertigo had ceased. She was unable to state that objects took any particular course during the attacks or that she felt any tendency to fall in any particular direction.

During the six months in which she may be considered to have been under my treatment she was for some time given a drachm of quinine daily in three doses, each dose being administered with a drachm of hydrobromic acid. She also took iodide, strychnine, belladonna, and mercury; yet during this time not only did she obtain no relief but her attacks increased in frequency, often recurring after an interval of only one day, though for the last two years and more she had never been free from an attack for a period of

NOTE ON THE LYMPHATIC GLANDS IN SLEEPING SICKNESS.[1]

By E. D. W. Greig, M.B., C.M. Edin.,
CAPTAIN, I.M.S.,
AND
A. C. H. Gray, M.B. Lond., M.R.C.S. Eng., L.R.C.P. Lond.,
LIEUTENANT, R.A.M.C.

Following a suggestion of Dr. F. W. Mott we have examined the contents of lymphatic glands during life from 15 sleeping sickness patients. In all of them actively motile trypanosomes were very readily found in cover-glass preparations taken from the cervical glands. They were also present in other glands, such as the femoral, but were not nearly so numerous. We found the trypanosomes to be far more numerous in the glands than in the blood or cerebro-spinal fluid and we believe that the examination of fluid removed from lymphatic glands will prove to be a much more rapid and satisfactory method of diagnosing early cases of sleeping sickness than the examination of the blood.

At first the glands were excised but this was soon found to be unnecessary, as it is easy to puncture a superficial gland with a hypodermic syringe and to suck up some of the juice into the needle and to blow this out on a slide. The actively moving trypanosomes were readily found after a short search in these slides, when a prolonged search in similar preparations of the blood from the finger failed to discover them. In stained specimens, in addition to well-formed trypanosomes, there exist many broken-down remains which suggests that a destruction of the trypanosomes takes place in the glands. We also examined the cervical lymphatic glands of the five natives suffering from trypanosomiasis who have been under observation for the past year and found actively motile trypanosomes in the liquid withdrawn from the glands in all of them. One of these patients is employed in the hospital and the dispenser reports that he is getting very stupid. The lymphatic glands were also examined for streptococci by staining and culture, but in every case were found to be sterile. Some of the cases, the glands from which were examined for streptococci, were very far advanced. The streptococcus invasion must, in our opinion, be a very late one and only occur shortly before death. Observations made upon the blood show a constant increase in the percentage of lymphocytes but the total leucocytes are not increased.

We consider that these observations throw a new light upon the glandular enlargements which have been so constantly noticed in sleeping sickness and that the disease is essentially a polyadenitis brought about by the arrest of the trypanosomes in the glands where many of them are destroyed, but whence some escape from time to time into the blood-stream and thus occasion the increase which has been observed in the peripheral circulation. We regard our observations upon the presence of trypanosomes in number in the lymphatic glands of both early cases of trypanosomiasis and advanced cases of sleeping sickness as affording important evidence of the unity of these diseases and further proof that the trypanosomes are the essential cause of sleeping sickness.

NOTE ON A CASE OF HYDROA DURING PREGNANCY WITH RECURRENCE AT THE MENSTRUAL PERIODS.

By C. A. Douglas Bryan, M.R.C.S. Eng., L.R.C.P. Lond.

The notes of the following case are interesting in that they describe a rare condition with a still rarer complication.

The patient, who was a married woman, came to see me on *Sept. 1st, 1903, concerning a rash that had appeared during* the previous week on her arms, thighs, and trunk, more especially on her arms; she was at the time about five and a half months pregnant. The rash on the arms was vesicular, very painful, and irritating; the vesicles were continually bursting, while fresh crops kept appearing; the fluid from the vesicles gave a scalding sensation to the arms. The rash on the thighs and trunk was papular only and very irritating. The diagnosis of hydroa gravidarum was made. Various remedies were tried locally, such as lead, resinol, and thiol, and arsenic was given internally. Thiol (used as an ointment and dusting powder) gave most relief. The irritation and pain were at times so great that opium had to be administered and serious thoughts were entertained of inducing premature labour. About Sept. 29th the fœtus died. The rash had by this time extended in its papular form to the face. Labour soon after this set in and the woman was delivered on Oct. 9th of a stillborn fœtus. The rash now for the most part soon disappeared, except for some slight irritation about the arms. The patient's recovery from the confinement was hindered by the development of pleurisy with effusion on the seventh day; this eventually cleared up satisfactorily. The catamenia commenced about a month after delivery and have continued regularly every month up to the present. At each menstrual period the arms swelled slightly, small spots appeared, and there were irritation and slight pain; this cleared up between the periods. For the last two months she has been free from the rash, &c. As to the causation of the disease nothing could be made out. The patient had had four children at full time and a serious abortion one and a half years ago; she had never before had any skin eruption and had enjoyed average good health. During this last pregnancy, up to the appearance of the rash, she had been remarkably well, and while the rash was in evidence her health did not suffer beyond the fact of the want of sleep. The urine on examination was found to be normal.

The internal administration of arsenic did not seem to have any influence whatever on the course of the disease. The local applications were far from satisfactory, though, as I have mentioned above, thiol gave slight relief. The other point of interest in the case was the recurrence of some of the symptoms at the subsequent menstrual epochs. So far as I am aware this latter condition has never before been observed. I should be glad to hear of any other cases, the line of treatment pursued, and with what results.

ST. BARTHOLOMEW'S HOSPITAL.

A CASE OF VERTIGO DUE TO LABYRINTHINE CARIES; OPERATION ON THE LABYRINTH; COMPLETE RECOVERY.

(Under the care of Mr. A. E. Cumberbatch and Mr. O. Ernest West.)

The patient, a woman, aged 22 years, first came under treatment at St. Bartholomew's Hospital about the beginning of April, 1903, complaining of pain in, and discharge from, the right ear. After some weeks of treatment as an out-patient she was admitted on account of persistent headache and tenderness over the upper part of the right mastoid. Under Mr. Cumberbatch's supervision a typical post-aural operation was performed and she made a good recovery. At the time of her discharge she complained of some slight giddiness and on August 4th she was readmitted with headache, muscular weakness, and marked ataxic gait. There was nothing to remark about the operation cavity which was healthy but incompletely "scarred." The temperature was normal and the pulse was 80. The right mastoid region and the area above it were tender and painful. When attempting to walk she immediately drifted to the right and if not supported fell to this side after a few steps. Her track strikingly resembled that of a sheep with a cerebellar cyst. On sitting up in bed she also fell to her right side. There were no ocular symptoms. The knee-jerks were equal and active. No clonus was present at the knee or the ankle. There were continual fibrillar twitchings of the right arm and leg and distinct weakness of the right grip. At this stage Mr. Cumberbatch left London on his summer holiday and Mr. West was left on duty for him. Mr. Cumberbatch's opinion was that the symptoms were due to caries affecting the labyrinth.

---

[1] Read before the Royal Society on May 5th, 1904.

During the next ten days the headache continued and the pulse grew slower, sinking once to 64. There was no mental dulness but much lassitude. On August 14th a loose sequestrum of somewhat pyramidal form was removed by forceps. Its base formed a part of the upper and anterior portion of the inner tympanic wall and its apex passed inwards above the cochlear region. On the 17th she was sick once. The temperature was 96·6° F. and the pulse was 60. There was slight haziness of the right optic disc. Her condition was stationary until the 25th and the presence of a cerebellar abscess was considered probable. With the knowledge that carious processes were present and to exclude extradural causes a very wide operation was performed on this day through the old mastoid scar. The cavity was enlarged upwards and backwards, the tegmen was freely cut away, and the lateral sinus and the dura mater in its neighbourhood were exposed. The dura mater was found normal in both regions. A further sequestrum was removed from the cochlear region. The patient made an excellent recovery, the pain and tenderness diminished, and the giddiness for the time almost disappeared. The whole cavity rapidly became covered with epithelium and dry with the exception of one small moist patch in the region of the promontory. The right ear was quite deaf. Early in October she had some return of pain and again became very giddy and this condition remained and grew slowly worse through the autumn and winter. During all this time she was carefully watched. The moist patch persisted but all the upper and posterior part of the cavity was dry, smooth, and shining.

On April 11th, 1904, she was again admitted. Her giddiness was very severe and a small fresh granulating area had appeared in the region of the external semicircular canal. Mr. Cumberbatch very kindly allowed Mr. West to consider the case as his own as he had previously operated on it in his absence.

On April 12th, after disinfecting the cavity so far as possible, Mr. West made an extended incision through the old scar and turned the auricle freely forward. The region of the outer limb of the external semicircular canal was found carious and scraping left a hollow there of about the size of half a large pea. This was then enlarged by the burr upwards to the dura mater and forwards above the level of the facial aqueduct until the outer limb of the superior semicircular canal must have been cut away and the bone was everywhere of ivory hardness. There was no facial twitching. Attention was now turned to the tympanum. A cavity was opened anteriorly in the cochlear region and this was extended by cutting away its walls with a small sharp spoon until there appeared a smooth deep hollow occupying the entire region of the cochlea and vestibule. Working backwards and upwards finally produced one sharp facial twitch and it was decided to go no further. Between the cavity above and the cavity below there remained a narrow prominent bony ridge which must have contained the facial canal. The wound was completely closed behind the ear and the cavity was lightly plugged from in front.

Convalescence was somewhat delayed by a slight suppuration in the upper end of the wound. There was no facial paralysis. The temperature continued to make small daily excursions until April 19th when it finally sank to normal. From the day after the operation the patient noticed the complete disappearance of her giddiness which had previously annoyed her even when in bed. On the 26th she was walking about the ward. On May 3rd the cavity was rapidly becoming covered with epithelium. She could now stand with her heels together and eyes shut without swaying, and has since continued entirely free from vertigo.

Remarks by MR. WEST.—The above case is of interest from the persistence and severity of the vertigo, the difficulties which occurred in identifying its cause, and the marked success which finally resulted from a determined attack on the labyrinth. Obviously as long ago as August, 1903, the patient's cochlea was invaded by caries and functionally destroyed. For seven months afterwards she suffered from continued irritation of her vestibular nerve. In the earlier part of this time it was hoped that this was due to scarring after past changes and would subside. No improvement took place, however; rather her vertigo increased and, as was made evident at the last operation, there had continued a slowly progressive caries. In view of the obstinacy of the trouble a systematic effort was made to destroy as much of the labyrinth as was accessible and to drain any remainder so thoroughly as to do away permanently with its functional activity. The main risk of such an operation is to the facial nerve which lies in its tympanic part between the region of the canals and that of the cochlea and vestibule and can only have a narrow bar of bone left to support it between the two. With adequate opening up of the cochlea and vestibule the risk of leptomeningitis by extension through the internal auditory meatus is probably small.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

On the Elasticity of the Aorta, being a Contribution to the Study of Arterial Sclerosis.

A MEETING of this society was held on May 31st, Sir R. DOUGLAS POWELL, Bart., the President, being in the chair.

Dr. W. P. HERRINGHAM and Dr. W. A. WILLS communicated a paper on the Elasticity of the Aorta, being a Contribution to the Study of Arterial Sclerosis. They said that they had examined a large number of aortas and had found that after extension they all recoiled to their original length but that the degree to which they stretched varied greatly. It was to the consideration of this latter point that their paper was devoted. Having referred to, and analysed, the work of previous authors they proceeded to describe the instrument which they had used for the purpose of their investigations. It consisted of a lever of the first order with a long arm on which travelled a weight. At the end of the arm was a pen which wrote on a flat board travelling at the same rate as the weight with the result that a curve was formed the abscissæ of which recorded the weight and the ordinates the degree of elasticity of the aorta. The instrument was founded on that invented by Roy. The material used comprised 100 male and 28 female aortas; the latter were less elastic or extensible than the former but in other respects obeyed the same laws and were not referred to in detail. The 100 cases were almost equally distributed between the third, fourth, fifth, sixth, and seventh decades of life and in each case the age, the width and condition of the aorta, the weight and condition of the heart, the fatal and coincident diseases were recorded, and the condition of elasticity as shown by the curve was measured under pressures of 50, 100, 150, and 200 grammes. After describing the histological changes in detail Dr. Herringham and Dr. Wills summarised their conclusions as follows: (1) the aorta follows the law laid down by Wertheim for the elasticity of organic bodies; (2) its width increases with age as the result of internal pressure exercised upon it by the natural forces of the circulation; (3) the more it thus becomes dilated the less is it capable of being further stretched; (4) when stretched by weights up to 200 grammes aortas, even when dilated, retain the power of returning to their original volume; (5) no simple mathematical relation obtains between dilatation and loss of elasticity; (6) elasticity depends chiefly upon the tunica media and the loss of it chiefly on changes in the same coat; (7) these changes do not lie in the muscular tissue; (8) the amount of muscular tissue, though varying in individuals, probably, except in rare cases, remains the same in each individual throughout adult life; (9) the tunica media increases in substance with age; (10) this increase is to be ascribed to the elastic or to the structureless connective tissue or to both; (11) it is to changes in these latter tissues that the loss of elasticity is to be ascribed; and (12) the

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

NOTE ON THE LYMPHATIC GLANDS IN SLEEPING SICKNESS.[1]

By E. D. W. Greig, M.B., C.M. Edin.,
CAPTAIN, I.M.S.,
AND
A. C. H. Gray, M.B. Lond., M.R.C.S. Eng., L.R.C.P. Lond.,
LIEUTENANT, R.A.M.C.

FOLLOWING a suggestion of Dr. F. W. Mott we have examined the contents of lymphatic glands during life from 15 sleeping sickness patients. In all of them actively motile trypanosomes were very readily found in cover-glass preparations taken from the cervical glands. They were also present in other glands, such as the femoral, but were not nearly so numerous. We found the trypanosomes to be far more numerous in the glands than in the blood or cerebrospinal fluid and we believe that the examination of fluid removed from lymphatic glands will prove to be a much more rapid and satisfactory method of diagnosing early cases of sleeping sickness than the examination of the blood.

At first the glands were excised but this was soon found to be unnecessary, as it is easy to puncture a superficial gland with a hypodermic syringe and to suck up some of the juice into the needle and to blow this out on a slide. The actively moving trypanosomes were readily found after a short search in these slides, when a prolonged search in similar preparations of the blood from the finger failed to discover them. In stained specimens, in addition to well-formed trypanosomes, there exist many broken-down remains which suggests that a destruction of the trypanosomes takes place in the glands. We also examined the cervical lymphatic glands of the five natives suffering from trypanosomiasis who have been under observation for the past year and found actively motile trypanosomes in the liquid withdrawn from the glands in all of them. One of these patients is employed in the hospital and the dispenser reports that he is getting very stupid. The lymphatic glands were also examined for streptococci by staining and culture, but in every case were found to be sterile. Some of the cases, the glands from which were examined for streptococci, were very far advanced. The streptococcus invasion must, in our opinion, be a very late one and only occur shortly before death. Observations made upon the blood show a constant increase in the percentage of lymphocytes but the total leucocytes are not increased.

We consider that these observations throw a new light upon the glandular enlargements which have been so constantly noticed in sleeping sickness and that the disease is essentially a polyadenitis brought about by the arrest of the trypanosomes in the glands where many of them are destroyed, but whence some escape from time to time into the blood-stream and thus occasion the increase which has been observed in the peripheral circulation. We regard our observations upon the presence of trypanosomes in number in the lymphatic glands of both early cases of trypanosomiasis and advanced cases of sleeping sickness as affording important evidence of the unity of these diseases and further proof that the trypanosomes are the essential cause of sleeping sickness.

NOTE ON A CASE OF HYDROA DURING PREGNANCY WITH RECURRENCE AT THE MENSTRUAL PERIODS.

By C. A. Douglas Bryan, M.R.C.S. Eng., L.R.C.P. Lond.

THE notes of the following case are interesting in that they describe a rare condition with a still rarer complication.

The patient, who was a married woman, came to see me on Sept. 1st, 1903, concerning a rash that had appeared during the previous week on her arms, thighs, and trunk, more especially on her arms; she was at the time about five and a half months pregnant. The rash on the arms was vesicular, very painful, and irritating; the vesicles were continually bursting, while fresh crops kept appearing; the fluid from the vesicles gave a scalding sensation to the arms. The rash on the thighs and trunk was papular only and very irritating. The diagnosis of hydroa gravidarum was made. Various remedies were tried locally, such as lead, resinol, and thiol, and arsenic was given internally. Thiol (used as an ointment and dusting powder) gave most relief. The irritation and pain were at times so great that opium had to be administered and serious thoughts were entertained of inducing premature labour. About Sept. 29th the fœtus died. The rash had by this time extended in its papular form to the face. Labour soon after this set in and the woman was delivered on Oct. 9th of a stillborn fœtus. The rash now for the most part soon disappeared, except for some slight irritation about the arms. The patient's recovery from the confinement was hindered by the development of pleurisy with effusion on the seventh day; this eventually cleared up satisfactorily. The catamenia commenced about a month after delivery and have continued regularly every month up to the present. At each menstrual period the arms swelled slightly, small spots appeared, and there were irritation and slight pain; this cleared up between the periods. For the last two months she has been free from the rash, &c. As to the causation of the disease nothing could be made out. The patient had had four children at full time and a serious abortion one and a half years ago; she had never before had any skin eruption and had enjoyed average good health. During this last pregnancy, up to the appearance of the rash, she had been remarkably well, and while the rash was in evidence her health did not suffer beyond the fact of the want of sleep. The urine on examination was found to be normal.

The internal administration of arsenic did not seem to have any influence whatever on the course of the disease. The local applications were far from satisfactory, though, as I have mentioned above, thiol gave slight relief. The other point of interest in the case was the recurrence of some of the symptoms at the subsequent menstrual epochs. So far as I am aware this latter condition has never before been observed. I should be glad to hear of any other cases, the line of treatment pursued, and with what results.

ST. BARTHOLOMEW'S HOSPITAL.

A CASE OF VERTIGO DUE TO LABYRINTHINE CARIES; OPERATION ON THE LABYRINTH; COMPLETE RECOVERY.

(Under the care of Mr. A. E. CUMBERBATCH and Mr. C. ERNEST WEST.)

THE patient, a woman, aged 22 years, first came under treatment at St. Bartholomew's Hospital about the beginning of April, 1903, complaining of pain in, and discharge from, the right ear. After some weeks of treatment as an out-patient she was admitted on account of persistent headache and tenderness over the upper part of the right mastoid. Under Mr. Cumberbatch's supervision a typical post-aural operation was performed and she made a good recovery. At the time of her discharge she complained of some slight giddiness and on August 4th she was readmitted with headache, muscular weakness, and marked ataxic gait. There was nothing to remark about the operation cavity which was healthy but incompletely "scarred." The temperature was normal and the pulse was 80. The right mastoid region and the area above it were tender and painful. When attempting to walk she immediately drifted to the right and common situation for these tumours.—Dr. C. W. Chapman inquired whether the vomiting was likely to be accounted for by the condition of the kidneys.—Dr. William Ewart described a similar case in which he had diagnosed mitral stenosis during life and in which a pedunculated clot was found post mortem in the left auricle which was capable of causing an intermittent blocking action of the mitral valve. —Dr. Parkinson referred to a specimen that he had exhibited before the Society for the Study of Disease in Children in which there were three organised thrombi situated in the right auricle, one of them being pedunculated.

---

[1] Read before the Royal Society on May 5th, 1904.

Mr. Stephen Paget exhibited a case of Osteitis Deformans.

The report of the council and the treasurer's statement of accounts were presented and the following gentlemen were elected to hold office for the year 1903-4:—President: Dr. Frederick Taylor. Vice-Presidents: Sir William R. Gowers, Dr. F. de Havilland Hall, Dr. J. Kingston Fowler, Mr. Henry Morris, Mr. C. H. Golding-Bird, and Mr. H. T. Butlin. Treasurer: Mr. G. H. Makins. Council: Dr. F. E. Batten, Dr. Harry Campbell, Dr. J. Walter Carr, Dr. W. S. Colman, Dr. Norman Dalton, Dr. W. Lee Dickinson, Dr. E. W. Goodall, Dr. F. H. Hawkins, Dr. Percy Kidd, Dr. Hector W. G. Mackenzie, Mr. F. W. Strugnell, Mr. Herbert W. Allingham, Mr. Anthony A. Bowlby, Mr. Walter Edmunds, Sir Alfred D. Fripp, Mr. J. Hutchinson, jun., Mr. T. H. Kellock, Mr. B. G. A. Moynihan, Mr. C. S. Wallace, and Mr. F. C. Wallis. Honorary secretaries: Dr. William Pasteur and Mr. W. G. Spencer.

Glasgow Obstetrical and Gynæcological Society.—A meeting of this society was held on May 25th, Dr. J. Nigel Stark, the President, being in the chair.—Dr. J. K. Kelly showed two specimens of Extra-uterine Pregnancy.—Dr. Miller showed (for Mr. J. Stuart Nairne: 1. A Tube and Ovary enveloped in Adhesions. The tube contained a blood clot but there was no evidence of a pregnancy. 2 A Hydrosalpinx.—Dr. J. M. Munro Kerr read notes of a case of Spontaneous Rupture of the Uterus during Pregnancy through the cicatrix of a Cæsarean section wound. The patient, a tertipara, was admitted to the Glasgow Maternity Hospital on Oct. 28th, 1901. In both the previous labours the children were dead. On the last occasion craniotomy was done. On this occasion Dr. Kerr performed Cæsarean section, employing Fritsch's fundal incision. The patient made a good recovery. On her second admission she was judged to be in her thirtieth week. After an enema given about midnight she complained of pain in the epigastrium but shortly afterwards fell asleep. Next morning the pain had spread over the whole abdomen but there was no vomiting and the pulse was not accelerated. Later in the day tenderness became more marked, the pulse rose to 90, the temperature became subnormal, and the breathing more rapid. The patient lay with her feet slightly drawn up and on palpation the fœtal parts could be made out with great readiness. There was some blood-stained vaginal discharge. Laparotomy was performed on the same day. On the abdomen being opened a large quantity of dark-coloured blood escaped and the intact membranes and placenta with the inclosed fœtus presented. The uterus lay retracted behind and was found to have a transverse rupture through the cicatrix of the previous Cæsarean section. The uterus was removed by supravaginal hysterectomy. The patient was dismissed well a month after the operation.—Professor Murdoch Cameron read notes of a case of Large Mesenteric Cyst. The patient, aged 32 years, was admitted to the Western Infirmary on Sept. 26th, 1903, with the history of swelling of the abdomen of 12 years' duration. The swelling had given no trouble until a fortnight previously to admission when she had an attack of severe pain in the region of the umbilicus. Fluctuation was very distinct but no nodules could be made out. Examination per vaginam was negative. On the 29th abdominal section was performed and 33 pints of thin, greenish-yellow fluid were evacuated. The cyst was very thick-walled and adherent over the whole surface. It seemed to be entirely encircled by omentum. The ovaries were quite healthy. The patient made a good recovery. The fluid from the cyst was slightly alkaline and of specific gravity 1011. It contained considerable numbers of exceedingly fatty leucocytes and larger cells resembling endothelial cells. Free fat globules were also present as well as a small number of red blood corpuscles. The fluid also contained a small amount of albumin. The cyst was practically unilocular, although partial septa existed.—Dr. Lindsay and Dr. Taylor related a case of Diaphragmatic Hernia in a Seven Months Fœtus. 12 months previously the mother had given birth to an eight months child. The medical man in attendance stated that the heart was beating on the right side. This was also the case with the specimen shown. In the present case the right half of the diaphragm was complete. There was a large round opening in the left half of the diaphragm. The stomach, duodenum, most of the small intestine, cæcum and appendix, ascending and transverse colon, spleen, and the left lobe of the liver were thrust through the diaphragmatic opening into the thorax, carrying before them the pleura and the peritoneum which together formed a complete hernial sac. The left lung was crowded into the upper part of the thorax. The heart and pericardium were normal except that the apex of the heart lay to the right of the middle line.

Windsor and District Medical Society.—A meeting of this society was held at the Guildhall, Windsor, on May 25th, Mr. W. B. Holderness, the President, being in the chair.—Microscopical preparations were exhibited illustrative of Carcinoma of the Breast, Carcinoma of the Stomach, Trichiniasis, Splenic Leukæmia, and Chondrosarcoma of the Parotid Gland.—The time of the meeting was mainly occupied by the examination and discussion of the cases exhibited. These consisted of a typical case of Exophthalmic Goitre in a young woman shown by the President.—Dr. W. F. Lloyd showed a young child with a Congenital Malformation of the Toes. There were undue mobility of the metatarso-phalangeal joints and considerable inward displacement of the hallux when the foot touched the ground.—Dr. G. E. Hale showed a male patient with High Myopia and considerable Pigmentary Choroiditis. The latter was thought to be specific in origin.—Dr. C. R. Elgood showed (1) a man, aged 39 years, presenting well-marked symptoms of Locomotor Ataxy; and (2) a boy, aged ten years, with Wasting of the Muscles of the Right Upper Limb. There was the history of an injury. The case was judged to be one of subacute anterior poliomyelitis.—Mr. J. H. Tomlinson exhibited and demonstrated the use of an instrument which consisted of a simplified form of Abney's Colour Patch Apparatus adapted for the consulting room.—A vote of thanks to Mr. Tomlinson for his interesting demonstration terminated the proceedings.

British Electro-Therapeutic Society.—A meeting of this society was held on May 27th, Dr. Lewis Jones, the President, being in the chair.—Dr. G. H. Graham showed a young woman, aged 22 years, with the following Deformity: the left humerus with its head measured only two inches and there was absence of the left radius, three carpal bones, two metacarpals, the phalanges of the thumb, and two fingers. The skiagraph was shown which clearly indicated the absence of the above-mentioned parts.—Dr. A. W. Sikes read notes of a case of Persistent Sinus of the Abdomen after Appendicitis (non-tuberculous) which had resisted all forms of treatment but which had yielded to the local administration of high-frequency currents with a probe electrode.—Dr. H. Manders read a paper on the Choice of Method in the Therapeutics of High-frequency Treatment. The paper dealt chiefly with the physical aspect of the subject and methods of effluvation and derivation. Several members took part in the discussion which ensued.

Kidderminster Medical Society.—A meeting of this society was held on May 27th, Mr. W. Hodgson Moore, the President, being in the chair.—Mr. J. Lionel Stretton showed a woman upon whom he had performed the operation of Gastro jejunostomy on March 26th, 1903, the approximation being accomplished by means of a Murphy's button which was not passed until April 10th, 1904, more than 12 months after the operation. The patient was now well and free from discomfort. He also showed a Dermoid Cyst.—Dr. J. Brocket showed a Cæcum which had perforated owing to an annular stricture in the sigmoid region. The case had presented no urgent symptoms until after the perforation had occurred. He also showed two greatly contracted Granular Kidneys removed from a man who died from suppression of urine; previously to his death he passed no urine for seven days. He became comatose a few hours before death. —Mr. A. O. Oldham read an interesting paper on Moveable Kidney.

Reviews and Notices of Books.

Religion and Science: Some Suggestions for the Study of the Relations between them. By P. N. WAGGETT, M.A., of the Society of S. John the Evangelist. London: Longmans, Green, and Co. 1904. Pp. 174. Price 2*s.* 6*d.* net.

This work is one of a series of handbooks for the clergy edited by Arthur W. Robinson, vicar of All Hallows, and the fact that one of these handbooks should be devoted to the study of the relations between religion and science marks the growth of a broader spirit of inquiry amongst the religious teachers of the day. Many regard religion and science as antagonistic, this view being perhaps fostered by imperfect knowledge or indifference on either side. Religion is often understood to be a question of unreasoning faith, while science is thought to be influenced solely by a spirit of sceptical inquiry. Each has suffered from lack of sympathy with the aims and methods of the other, and when we meet with such thoughtful and sympathetic work as we find in this little volume it is a pleasure to examine it carefully and to ascertain how far it succeeds in showing the bearing of natural science upon religious faith and practice.

Father Waggett has approached this very difficult subject with a mind open to all aspects of religion and scientific truth; he has studied evolution and biology with full knowledge of the difficulties which must arise when it is so much easier to raise questions than to provide answers. Since members of the clerical profession have realised that scientific doctrine is complicated and hard to master they have, as a rule, neglected the study of science or have been content with a "moderately laborious research." Father Waggett rightly warns his readers, that is, the clergy, that few things are so perilous as knowledge lightly won. He maintains that a discussion of the scientific criticism of religion is valuable in proportion to the knowledge of science and of religion of the parties to the discussion: those who know most will be slowest to claim competent or satisfactory knowledge in either field. The author deplores the present relation between science and religion, which he regards not as a truce between two opposing camps but as a state of indifference, in which each side considers itself immune to the poisons of the other's doubts and remains untouched by the splendours of the other's truths. Each is content to work independently and to refrain from criticising the statements of the other. The author regrets this apathy and would gladly exchange it for a return to weekly conflicts on the narrowest issues, fought on the narrowest lines, rather than see a perpetuation of the present cold separation between the great thinkers of the day. He argues that working hypotheses may be compared to the use of an alloy; they may be necessary before a scientific truth can be grasped, but he regards truth as pure gold, the alloy as the convenient addition which enables the workman to perform his part. The theory of natural selection is instanced as a possible "alloy" which, even if abandoned, will be found to have advanced the great truth of development. On the proper appreciation of the theories of natural selection, evolution, and heredity Father Waggett's remarks are extremely suggestive; he holds that these theories are not opposed to revealed religion and indicates that each in turn presents difficulties which cannot be solved with existing scientific data. He thinks that the doctrine of heredity has been twisted to involve the futility of personal effort. He boldly admits that efforts to conciliate religion and science must frequently fail and that there must always be a clash of opposing beliefs, but he takes comfort in the thought that life is essentially composed of a resistance to certain forces and must cease when the struggle comes to an end. To attempt to secure peace by restating religion in scientific terms, or by relegating material evidence to a secondary place by the assertion of the idealism of religion, fails to satisfy. The conclusion that is reached is that religion requires faith, obedience, and hope transcending the evidence of the senses, and that the doubting spirit can receive no comfort nor can religion be served by the fact that the existence of a Great First Cause can be proved as men prove the existence of an Ice Age. He believes that, though in the past religion and science have been hindered by the supposed conflict between them, yet in the future each may serve the other and that the true cure for religious doubts will be found in the scientific treatment and pursuit of religion itself.

We have endeavoured to show the general scope and aim of this little handbook and we think Father Waggett is right in considering that "it raises more questions than it settles." It is a thoughtful attempt to stimulate inquiry and if occasionally the argument is so condensed that it requires careful and close reading and thinking this result has probably been desired by the author. It might have been easier to the author to treat the subject superficially but the educational value of the book would not have been so great

---

Scientific Memoirs by Officers of the Medical and Sanitary Departments of the Government of India: A Preliminary Report on a Parasite found in Persons suffering from Enlargement of the Spleen in India. By Lieutenant S. R. CHRISTOPHERS, M.B. Vict., I.M.S. New series. No. 8. Calcutta: Office of the Superintendent of Government Printing, India. 1904. Pp. 17. Price 1 rupee, 8 annas.

LIEUTENANT CHRISTOPHERS, already well known by his previous good work on malaria, was directed by the Government of India to proceed to Madras and to investigate the nature of parasites that had been discovered there by Captain C. Donovan, I.M.S., in enlargement of the spleen. The history of this discovery is as follows. In 1900 Major W. B. Leishman, R.A.M.C., the present Professor of Pathology at the Royal Army Medical College, discovered these particular parasites during the examination of a film taken post mortem from the spleen of a case of fever contracted in Dum-Dum. He described them in a paper in May, 1903. The constant presence of chromatin masses found in the bodies suggested to Major Leishman that the latter might possibly be the remains of trypanosomata and that similar cases of so-called malarial fever might in reality be cases of trypanosomiasis. In July, 1903, Captain Donovan found similar bodies in blood taken from cases by splenic puncture during life. He, however, considered them to be a new form of parasite, as he failed to find trypanosomata in the blood. Specimens were sent to Major R. Ross, to Professor Laveran, and to Professor Mesnil. Major Ross also came to the conclusion that they were a new form of parasite and proposed to call it Leishmania Donovani. In 1904 Professor Marchand and Dr. Ledingham found similar bodies in the spleen, the liver, and the bone marrow. Professor Laveran and Professor Mesnil in the meantime having examined the specimens sent to them concluded that the parasite was a new species of piroplasma and named it the piroplasma Donovani. Such was the position of affairs when Lieutenant Christophers's investigation was made. He examined many cases in Madras and the tissues at three necropsies, and in addition compared the human parasites with those of two species of piroplasmata, one in the calf and the other in a pariah dog.

The report details the clinical features of the cases in which the parasites were found; their post-mortem appearances; the relation of the disease to kala-azar; the description of the parasite and its distribution in the body; the comparison of the parasite with a species of piroplasma; and, lastly, the nature of the so called "zooglea mass." As regards the clinical features of cases these were found to consist in great enlargement of the spleen, emaciation, irregular pyrexia, and certain abdominal symptoms such as diarrhœa and dysenteric condition with blood and mucus; œdema of the feet was sometimes but not constantly found to be present. The post-mortem appearances were also found to be distinctive, one of the most interesting being the presence of large ulcers with great thickening and congestion of the mucous membrane of the large intestine. Perforation was found in certain cases to have taken place. With regard to the relationship of the disease to kala-azar Lieutenant Christophers was unable to detect any increase in pigmentation or anything in the asthenia or the duration of the disease differing from what is usually present in ordinary cases of so-called "malarial cachexia with enlarged spleen." However, a specimen sent by Dr. Bentley to Captain Donovan from the spleen in a case of kala-azar presented very numerous examples of the bodies under investigation and Lieutenant Christophers accordingly concludes that if they are the cause of the disease then kala-azar and malarial cachexia with enlarged spleen must be essentially of the same nature.

A minute description of the parasites is included with some well-depicted illustrations. The bodies are seen in great numbers in an unchanged state in the *leucocytes*, especially being present in the large mononuclear cells. The distribution of the parasite in the body is detailed and the method of staining it by a modification of Romanowsky's stain is given. Finally, in comparing these bodies with certain species of piroplasma the essential differences of the latter to the bodies concerned in the human infection are pointed out, one of the most important being the absence of any appearance like the highly distended double chromatin masses. There is a complete absence also of the human parasite in the peripheral blood in all cases; in the case of piroplasma, however, the latter is found readily enough in some form or other in the peripheral blood. As the result of his researches Lieutenant Christophers shows the distribution of the parasite in the body to be very limited and that there is only a superficial resemblance to piroplasma. He concludes that the difference between the two forms is so great that strong evidence must be forthcoming before the new parasite can be placed in the genus piroplasma. He holds that the organism is distinct from piroplasma but that it is suggestive of the spores of a microsporidium. Finally, as regards the zooglea masses, the author considers that the substance is the protoplasm of the large cells in the liver and spleen and that these large cells are not themselves parasitic.

Pediatrics. By THOMAS MORGAN ROTCH, M.D. Fourth edition, rearranged and rewritten. London and Philadelphia: J. B. Lippincott Company. 1903. Pp. 1021. Price 25*s*.

IN preparing this the fourth edition of "Pediatrics," according to the statement in the preface Dr. T. M. Rotch has made certain changes and systematically revised the text. The volume can, however, hardly be described as other than a reprint of the third edition. We have compared these two latest editions page by page and have succeeded in finding only a few insignificant changes. That so few alterations have suggested themselves to the author tends to confirm the opinion which we had formed in respect of the third edition—namely, that it would be very difficult to improve upon it or to impeach its accuracy. We notice one important change, however, on p. 201. In a new paragraph the point is emphasised that during the early months *of life the substitution of the proteids of whey for the* proteids of whole milk is of the greatest advantage in the feeding of the majority of infants. To be able to control and to vary the respective percentages of lactalbumin and caseinogen in preparations of modified milk no doubt makes for progress in the science of infant feeding but unfortunately it further complicates an already involved method.

We are glad that Dr. Rotch remains firm as regards the accurate composition of milks although his views on the question have been strongly criticised both in this country and in America. It has been claimed in opposition to his postulates that mathematical accuracy is not required and that the limits of an infant's powers of adaptation as regards food are much wider than he admits. It is quite a misrepresentation of Dr. Rotch's views to infer that he insists upon mathematical accuracy or that he does not realise the extent of an infant's powers of adaptation. The point which he does insist upon is that infants should be fed on a system as accurate as circumstances allow and not by guesswork.

LIBRARY TABLE.

A Manual of Dental Anatomy, Human and Comparative. By C. S. TOMES, M.A., F.R.S. Sixth edition. London: J. and A. Churchill. 1904. Pp. 636, with 286 Illustrations. Price 12*s*. 6*d*. net.—In the preface to this edition the author remarks that "the accumulation of a somewhat voluminous literature, much of which, while falling short of carrying complete conviction, yet tends to unsettle the ideas hitherto prevalent upon such points as the methods of evolution and the homologies of the teeth, renders the task of presenting in small compass any general view of the subject one of ever-increasing difficulty." A perusal of the book, however, shows that he has accomplished his task in a most admirable manner. During recent years the numerous discoveries of fossil remains in different quarters of the earth have gone far to assist in the elucidation of certain problems of odontology. An example of this is to be found in the chapter on Proboscidia, where an account is given of the recent discoveries in Egypt in eocene formations of certain animals, the mœrotherium and palæomastodon, which throw considerable light on the dentition of the modern proboscidians. The chapter *on the Evolution of Tooth Forms* contains much that is new; the various theories are impartially considered, the author remarking that "for the present the determination of the homologies of the cusps set forth by Osborn seems to hold the field, though it may come to be modified in the future." The editing has been carefully carried out and the book thoroughly maintains its position as the standard work on the subject.

Catalogue by Harry W. Cox, Limited, Manufacturing Electricians. Manufacturers of all Apparatus in Connexion with X Rays, High Frequency, Electro-Therapeutic, Wireless Telegraphy, &c. *Offices, 9–11, Cursitor-street, Chancery-*lane, London, E.C. Pp. 113.—This small work is something more than a mere catalogue of apparatus though it will be sent gratuitously to all registered practitioners. It contains full descriptions of Cox's heavy discharge inductive coils, of the Mackenzie-Davidson motor mercury break, of the different kinds of interruptors, of x ray tubes, and of all the different apparatuses and implements necessary in x-ray work. There are sections devoted to the lamps for treatment of lupus and rodent ulcer and to high-frequency apparatus. The last 30 pages are entitled "Practical Hints to Beginners." They comprise a simple explanation of the x-ray apparatus, with instructions how to set about work, instructions for connecting and working Cox's base and portable x-ray coils, instructions for adjusting the "Cox" contact breaker, brief instructions for connecting and working the Mackenzie-Davidson mercury interruptor, instructions for using the electrolytic break and the Mackenzie-Davidson cross-thread localiser, and instructions for connecting up and working of

Reviews and Notices of Books.

Religion and Science: Some Suggestions for the Study of the Relations between them By P. N. WAGGETT, M.A., of the Society of S. John the Evangelist. London: Longmans, Green, and Co. 1904. Pp. 174. Price 2*s.* 6*d.* net.

This work is one of a series of handbooks for the clergy edited by Arthur W. Robinson, vicar of All Hallows, and the fact that one of these handbooks should be devoted to the study of the relations between religion and science marks the growth of a broader spirit of inquiry amongst the religious teachers of the day. Many regard religion and science as antagonistic, this view being perhaps fostered by imperfect knowledge or indifference on either side. Religion is often understood to be a question of unreasoning faith, while science is thought to be influenced solely by a spirit of sceptical inquiry. Each has suffered from lack of sympathy with the aims and methods of the other, and when we meet with such thoughtful and sympathetic work as we find in this little volume it is a pleasure to examine it carefully and to ascertain how far it succeeds in showing the bearing of natural science upon religious faith and practice.

Father Waggett has approached this very difficult subject with a mind open to all aspects of religion and scientific truth; he has studied evolution and biology with full knowledge of the difficulties which must arise when it is so much easier to raise questions than to provide answers. Since members of the clerical profession have realised that scientific doctrine is complicated and hard to master they have, as a rule, neglected the study of science or have been content with a "moderately laborious research." Father Waggett rightly warns his readers, that is, the clergy, that few things are so perilous as knowledge lightly won. He maintains that a discussion of the scientific criticism of religion is valuable in proportion to the knowledge of science and of religion of the parties to the discussion: those who know most will be slowest to claim competent or satisfactory knowledge in either field. The author deplores the present relation between science and religion, which he regards not as a truce between two opposing camps but as a state of indifference, in which each side considers itself immune to the poisons of the other's doubts and remains untouched ... rses to he splendours of the other's truths. Each ndependently and to refrain fror the other. The auth lly exchange it

ND MAGAZINES.

Annals of Op narrowest *jy.* Edited by H. V. WURDEMANN, M.D., and CLAUD A. WORTH, F.R.C.S. Eng. Published quarterly. British edition by Baillière, Tindall, and Cox, London. Price 21*s.*—The *Annals of Ophthalmology*, a very superior journal on the subject of which it treats, has completed its twelfth year of existence and with the commencement of the thirteenth it has begun the issue of a special English edition, presided over by Mr. Claud Worth. The *Annals* contain a large number of original communications as well as *résumés* of the ophthalmic progress in many countries by such well-known writers as Landolt, Nuel, Rampoldi, da Garda, Pinto, Snellen, Hansen, and others, none of whom receives any remuneration for his labours. The journal is well deserving of support and we trust that many of our readers who wish to keep themselves abreast of modern ophthalmic work will become subscribers to it.

SEWERAGE SCHEME FOR CHRISTCHURCH.—The Local Government Board has intimated its approval of the Christchurch (Hampshire) *sewerage scheme which is* estimated to cost about £29,000. The population of the town is 3838.

---

must cease when the struggle comes to an end. To attempt to secure peace by restating religion in scientific terms, or by relegating material evidence to a secondary place by the assertion of the idealism of religion, fails to satisfy. The conclusion that is reached is that religion requires faith, obedience, and hope transcending the evidence of the senses, and that the doubting spirit can receive no comfort nor can religion be served by the fact that the existence of a Great First Cause can be proved as men prove the existence of an Ice Age. He believes that, though in the past religion and science have been hindered by the supposed conflict between them, yet in the future each may serve the other and that the true cure for religious doubts will be found in the scientific treatment and pursuit of religion itself.

We have endeavoured to show the general scope and aim of this little handbook and we think Father Waggett is right in considering that "it raises more questions than it settles" It is a thoughtful attempt to stimulate inquiry and if occasionally the argument is so condensed that it requires careful and close reading and thinking this result has probably been desired by the author. It might have been easier to the author to treat the subject superficially but the educational value of the book would not have been so great

Scientific Memoirs by Officers of the Medical and Sanitary Departments of the Government of India: A Preliminary Report on a Parasite found in Persons suffering from Enlargement of the Spleen in India. By Lieutenant S. R. CHRISTOPHERS, M.B. Vict., I.M.S. New series. No. 8. Calcutta: Office of the Superintendent of Government Printing, India. 1904. Pp. 17. Price 1 rupee, 8 annas.

LIEUTENANT CHRISTOPHERS, already well known by his previous good work on malaria, was directed by the Government of India to proceed to Madras and to investigate the nature of parasites that had been discovered there by Captain C. Donovan, I.M.S., in enlargement of the spleen. The history of this discovery is as follows. In 1900 Major W. B. Leishman, R.A.M.C., the present Professor of Pathology at the Royal Army Medical College, discovered these particular parasites during the examination of a film taken post mortem from the spleen of a case of fever contracted in Dum-Dum. He described them in a paper in May, 1903. The constant presence of chromatin masses found in the bodies suggested to Major Leishman that the latter might possibly be the remains of trypanosomata and that similar

cordially approves lled malarial fever council of the union in reference to the scheme propos by the ritish Medical Association in respect of medical defence and agrees to aid the council of the union in maintaining the integrity of the union in its entirety as at present existing.

He said that the collective defence of the profession comprised in such work as bringing transgressors before the General Medical Council and the prosecution of quacks legitimately belonged to the British Medical Association It had been stated that the standing committees of the British Medical Association carried on the work of collective defence but no one ever saw the Association bringing anyone before the General Medical Council or prosecuting quacks in courts of law. As a matter of fact, collective defence was carried on by the Medical Defence Union and as the scheme put forward by the British Medical Association only provided for individual defence, therefore in the event of the Medical Defence Union coming to an end the work of collective defence would cease.

After Mr. P. MACLEOD YEARSLEY had seconded the motion Dr. E. R. FOTHERGILL urged that the meeting should not pass the motion; his contention was that all interested in the matter should meet at a round table and secure the formation of one society for medical defence.

Mr. W. S. NOCKOLDS then spoke and was followed by Mr. J. T. MACNAMARA who asked what guarantee there was that medical defence by one society would continue to be carried on by such a body, for it was clear that the right to start another society for medical defence was always open to anyone.

The motion was then put to the meeting and carried.

The usual formal motions were then propcsed, seconded, and passed practically without debate.

THE LANCET.

LONDON: SATURDAY, JUNE 4, 1904.

The General Medical Council and Medical Education.

THE present session of the General Medical Council will be chiefly memorable for the debates on Saturday and Monday last, which we report at considerable length this week. In both of these debates the attitude towards the Council of the Royal College of Physicians of London and the Royal College of Surgeons of England was sharply criticised and on the latter occasion the situation was not improved by the speeches which the representatives considered it their duty to deliver, though Mr. MORRIS's remarks were admirably thought out. This is much to be regretted, since it is evident that the Council and the English Royal Colleges are agreed concerning the general broad principles upon which improvement in medical education can be effected. It is easy to understand that many of the terms employed in the heat of debate may provoke strife, but temptations in this direction should be avoided. The medical profession is mainly concerned about the accurate adjustment of the points at issue between the Royal Colleges and the General Medical Council because the settlement of the differences now existing will bring peace and opportunity for attention to other matters. Interest in the progress of medical education is superior to quibbles about whether "recommendations" or "requirements" is the right word for the General Medical Council to employ when supervising the educational curriculum of a qualifying body. The claims of ancient privileges by the Royal Colleges must always be of the greatest sentimental value, but these again must not be allowed to withstand the course of progress.

The debate on Saturday, May 28th, was upon a motion by Sir VICTOR HORSLEY to the effect that the courses of study laid down in the new regulations relating to the first year of professional study and to the minimum length of courses of instruction to be required in chemistry, physics, and biology by the English Conjoint Board were "insufficient," the word "insufficient" implying report to the Privy Council who may, after hearing the body to which the report relates, withdraw from such body the right to hold qualifying examinations. The new regulations of the English Conjoint Board have evidently been framed with the direct desire to permit the study of preliminary scientific subjects to be pursued at recognised institutions other than medical schools. It is perfectly clear that the Royal Colleges are not favourable to the expensive development of separate courses of study in the ancillary sciences in connexion with all the medical schools—a view which most practical teachers share. They are prepared to be content with evidence that their students have enjoyed sufficient educational opportunities to enable them to pass examinations of a written and practical character, this being, by the way, the attitude taken up by the University of London. The new regulations and synopses of the Conjoint Board mark a genuine desire to improve the nature of their first professional examination, and in the satisfaction with which these changes should be greeted the tardiness of action and the stages of development might have been gracefully forgotten. Sir VICTOR HORSLEY thought otherwise and after the regulations had been formally received and entered in the minutes, he protested that the General Medical Council must be the supreme authority in medical education, that it did not recommend, it "required," courses of study and examination. This position is perfectly unassailable, there must be a supreme authority, a coördinating centre in educational matters. The General Medical Council practically fulfils the functions of a board of studies, where various views may be freely expressed and discussed and where some degree of harmony may be attained between the different examining bodies. Criticisms from such a body should be entitled to respect and it should never be necessary to enforce authority by reference to "requirements." In the regulations under consideration the Royal Colleges have made three noteworthy concessions to the wishes of the General Medical Council: the length of the minimum course of instruction in chemistry, physics, and biology has been furnished; whatever length of time is devoted to this instruction it is not to count for more than six months; and this preliminary scientific examination must be passed before attendance upon anatomy and physiology will be recognised. Dr. WINDLE made a good point in contrasting the regulations of the Conjoint Board with those of the University of London, and emphasised the educational importance of a well-ordered curriculum as compared with that of a severe examination. The contention of the Conjoint Board is that under their scheme each factor in education is properly looked after, thoroughly supervised institutions being alone recognised, and the character of the examination being adequate. Upon division Sir VICTOR HORSLEY's motion was lost by a large majority and the new regulations of the Conjoint Board were therefore regarded by the General Medical Council as "sufficient." But though victorious in the sense that they have satisfied the requirements of the Council the Royal Colleges have been reminded that they have been pugnacious and that they have not set the hoped for example of acquiescence in the judgment of the Council. The question is sure to arise again in the near future and in our opinion it can only be settled in one way.

And what that way will be was indicated by the debate in the Council on the following Monday, which was a no less stormy discussion of the position of the medical student at the commencement of his career. It was proposed that the Lord President of the Privy Council should be requested to introduce into Parliament a Bill to confer on the General Medical Council statutory power to establish and to maintain registers of medical and dental students and to impose a fee not exceeding £1 for registration therein. The arguments in favour of this innovation were extremely simple. Foremost is the fact that the expenses of the General Medical Council have for some years been exceeding the income and it was estimated that this new source of income would more than counterbalance the average loss. This argument might have been allowed to pass unchallenged but Sir JOHN BATTY TUKE explained further that the Council would have the power of approving or disapproving of the institutions recognised by various licensing bodies at which medical study could be begun. He endeavoured to be as impersonal as possible but stated generally that the licensing bodies would lose the right to nominate the educational institutions where the examinations in general education could be accepted. Similarly the right to nominate bodies at which medical education could be begun would be forfeited. As, of course, it is exactly this right for which the English Conjoint Board is contending and upon which the new educational scheme in respect of the preliminary sciences depends, the amplification of the intention of the motion furnished excuse for another heated debate. The representatives of the two Royal Colleges saw in the statutory registration of students and the payment of a fee threats to the chartered rights and powers of the licensing bodies. Dr. NORMAN MOORE, for the Royal College of Physicians of London, reproved the Council for its appetite for money and for increased powers, while Mr. HENRY MORRIS, for the Royal College of Surgeons of England, explained that the attitude of his College to the General Medical Council "was simply, so far as any opposition was concerned, one of defence and not one of defiance." These remarks supplied subsequent speakers with opportunities of forcible reply. The charters of the English Royal Colleges must naturally weigh much with the authorities of those Colleges and their representatives are carrying out their duty in attaching importance to them. But the Council is more likely to listen to the great argument of the Conjoint Board, that men qualified by the Board form upwards of half the Medical Register, than to any reference to ancient privileges put with however great sincerity and conviction. The debate closed with some admirable words from the President who took up this position while giving good reasons for supporting the motion, which was adopted by 22 votes against 6. These two discussions, although reaching right conclusions, cannot be said to reflect credit upon all of those who took part in them. The issues were simple on both occasions. There was no doubt that the general sense of the meeting would be in favour of conciliation during the first discussion on the regulations of the Conjoint Board; and there was equally no doubt that the General Medical Council would welcome the scheme of registration which should restore its solvency and increase its efficiency. Before these conclusions could be reached much valuable time had been spent in political strife which embitters relationships, increases antagonism, and is likely to impede progress in subsequent meetings.

◆

What is Brandy?

WE have never had any doubt as to the correct answer to the question "What is genuine brandy?" Brandy is spirit distilled from the fermented juice of the grape. As the readers of THE LANCET know, we took some pains a few years ago to lay before them all the facts connected with the brandy industry at Cognac and in the Charente district and to throw some light on the character of the brandy sold and consumed in this country. There can be no disguising the fact that of recent years a large section of the spirit trade has adopted a method of business which has hoodwinked the public. Spirituous liquors, chiefly brandy and whisky, have been placed upon the market which were not accurately described by the labels upon the bottles. We have pointed out again and again that the terms "brandy" and "whisky" had specific meanings, these terms being used to distinguish in the former case a spirit derived exclusively from wine and in the latter case a spirit derived from barley malt. We have been assured that the attenuation of genuine brandy or whisky with a spirit made from grain, potatoes, or other material was the result of the demand made by the public in favour of a spirit of negative rather than positive characteristics. It suited certain sections of the trade to say this, while all the time they knew perfectly well that their real object was to put upon the market a cheaper spirit and to gain a wider margin of profit upon it. Whatever else may be said such trading is not honest dealing with the public, apart altogether from the question of whether this or that spirit is more wholesome than the other. The point is that spirits are distinguished by certain names which, after all, imply positive characteristics. Brandy, whisky, and rum are distinguished by specific flavours derived not only from the materials from which they are made but from the manner in which they are distilled. It is true that chemistry has not given us as complete an insight as may be desirable on the question as to why one spirit differs from another in regard to its physiological action or its flavour. We do know, however, that there are important differences between the action of pure or plain spirit and a spirit distilled from the fermented juice of the grape or from malt in the simplest form of still, and these differences coincide with certain variations in the chemical composition of spirits.[1] In the production of plain or silent spirit every care is necessarily taken to eliminate positive characters. In fact, when the object is merely to produce neutral alcohol care is taken to obtain a spirit without flavour and without odour, the presence of which would, of course, indicate impurities so far as regards alcohol. On the other hand, in the production of spirit from the grape or from malt the object of the distiller is to preserve so far as possible the flavour of the original material. For the purposes of a beverage pure spirit is inadmissible because it is flavourless. Further, it is idle to contend that brandy and whisky are esteemed because they are merely alcohol. It is well known, and has been thoroughly recognised in clinical practice, that genuine well-matured brandy exerts a powerful physiological action which pure alcohol alone is not able to do. Genuine matured brandy possesses a well-known restorative power over and above that due to its alcoholic contents. That being so it is perfectly clear that when a person asks for brandy and gets a more or less plain spirit he is not receiving an "article of the nature, substance, and quality" demanded, and is obviously prejudiced.

It was with these plain facts in our minds that we decided some years ago to undertake a full investigation into the supply of brandy in this country. The results of this investigation appeared in our columns in the form of the report of our Special Analytical Commission on Brandy.[2] We felt at the time that this work was of the utmost importance to the public; we now realise that it has had influences of a greater magnitude than at first sight appeared, in that it has led to quite a campaign throughout the country being undertaken against the sale of spirit called brandy which in reality is not brandy. Discredit chemical analysis as many are inclined to do, they cannot shut their eyes to the fact that it was the results of analysis published in the report of THE LANCET Commission which has ultimately brought this species of fraud within the operation of the Sale of Food and Drugs Act. We are undisguisedly proud to have been the means of initiating what promises to be a reform of the utmost importance and interest both to the public and to the medical profession. The attitude of the spirit trade to us when the report of THE LANCET Commission appeared was not hostile, judging from the opinions expressed in the journals which voice the trade. It now seems clear, however, from the recent proceedings at the North London police court that the views we expressed and have since consistently adopted have led to a cleavage amongst brandy merchants. A wine merchant was summoned by the Islington borough council for selling as brandy "that which was not of the nature, substance, and quality" of brandy and was convicted after an exhaustive hearing. There were witnesses in this case, described as "leading members of the trade," who declared that if to plain or silent spirit were added sufficient Cognac brandy to give it the requisite flavour and aroma the blend would be brandy, and one witness further declared that during the 40 years that he had been in the trade brandy had never been considered to be a spirit exclusively derived from the grape. Another member of the trade in answering a question put to him by the magistrate said that he would regard a mixture of any spirit, whether from beetroot, potato, or grain, as genuine brandy. It seems to us that such representatives of the trade should be exposed.

---

[1] "The effects of alcohol on the blood pressure and lymph circulation are modified very considerably by the presence of other constituents in spirits, wines, &c." ...... Inasmuch as absolute ether gives us simply the cadiac stimulant curve it may be suspected that the ethers exert this modifying influence."—Dr. George Oliver in the Oliver-Sharpey Lectures on Recent Studies on the Tissue-Lymph Circulation, THE LANCET, April 30th, 1904, p. 1179.

The value of analysis in the case was impugned, together with the certificate describing the sample as containing 60 per cent. of spirit not derived from the grape, and yet the wholesale dealer who had supplied the sample to the defendant admitted that the opinion which he formed on purchasing the spirit was that it contained perhaps 40 per cent. of grain spirit, and he thought that the consignment sent to the defendant was "excellent value." One of the analysts for the defence said that he had made an analysis of the sample and the results were consistent, he maintained, with those obtained with a brandy derived from the grape, though he admitted that the amount of ethers was small. The evidence of the merchant who supplied the articles must have rudely upset this analyst's interpretation. We do not suggest that analysis can discriminate between the pure alcohol obtained from wine and that obtained from malt or sugar or any other material. Alcohol is alcohol whatever its source may be. But analysis easily differentiates between a pot-still and a patent-still spirit because of the secondary products, flavours, and so on, present in the former which are practically absent in the latter; and the amount and relationships of these secondary products vary considerably with the material from which they are derived. The quantities of ethers, aldehydes, acids, furfural, and higher alcohols are not the same in brandy as in whisky, neither are the amounts present in the same relation to each other.

The line of defence was ingenious and amounted to the following. It was assumed that brandy is correctly defined as a spirit distilled from wine or the fermented juice of the grape; then it followed that if the spirit from the grape were highly rectified by means of the patent or fractionating still, whereby secondary products characteristic of good brandy would be removed, the liquid would still be brandy. The magistrate took a very proper and decisive view of this argument. "He did not think," he said, "that after the spirit obtained by the distillation of wine had been so highly rectified as to have lost the properties peculiar to spirits so obtained it was still spirit obtained by the distillation of wine so as to fulfil the definition of brandy." Mr. FORDHAM may be heartily congratulated upon this very sensible acceptation of the meaning of brandy. Highly rectified spirit cannot for a moment be properly regarded as brandy even although nothing but grape may have been used in its production. Otherwise brandy could never be the medicinally valuable agent that it is universally admitted to be. The fact is, and the trade are bound to recognise it once for all, that the patent still has placed in the distiller's hands a machine which will enable him to refine alcohol from any source, whether it be good, indifferent, or thoroughly bad. The distiller knows also full well that with sick, sour, or inferior wines, or other not very choice materials, the use of the patent still is obligatory in order that the foul smells and evil flavours—evidences of unwholesomeness—may be eliminated by its agency. This is why the pot-still spirit is practically certain to be honest, for in a still of the simplest form of construction both the vices and virtues of the wine must come over with the spirit. It follows that only wine with virtues can be distilled in the pot still. Mr. FORDHAM had fine opportunities of considering the *pros* and *cons* of the case and he evidently bestowed considerable thought to its many aspects. The evidence was full of technicalities but he showed a perfectly clear grasp of the points presented to him, with the result that he has given a decision completely in harmony with commonsense. We hope that the issue of the case will do much to check the almost unbounded substitution which is being practised by the spirit trade. We cannot regard this decision in the slightest degree as a menace to the interest of the trade. They have only to deal fairly with the public by disclosing in accurate terms the nature of the article which they offer for sale. According to the view that the public exhibit a preference for mixtures or substitutes the trade ought not to lose by revealing the fact that the article is not a pure unblended spirit. Candour should put money in their purse on their own showing.

---

[2] THE LANCET, Nov. 29th, 1902.

The Relation of Human to Bovine Tuberculosis.

THE Royal Commission which, under the chairmanship of Sir MICHAEL FOSTER, was appointed to inquire into the relations of human and bovine tuberculosis as a result of the startling announcement made by Professor KOCH at the British Congress on Tuberculosis of 1901, has acted very wisely in issuing an interim report. Pending the issue of some such document there has been a tendency to go slow in the matter of prosecutions and to postpone fresh legislative action. The readers of THE LANCET will not be astonished at the result at which the commissioners have arrived, as we have from time to time drawn attention to the progress of the work done in this and other countries in connexion with this subject. As we pointed out in a leading article in THE LANCET of Oct. 31st, 1903, p. 1243, *the possibility of the transmission of tuberculosis* of human origin to bovines has been placed beyond dispute by the numerous experiments which have been carried out since KOCH and SCHUTZ obtained their negative results. At the same time we drew attention to the fact that the only points which were left over for discussion and experiment were the facility with which human tuberculosis can be transmitted to the bovine subject and the inferences which are to be drawn in respect of this danger to the public health The Royal Commissioners have now placed the seal of their authority upon results which are matters of common knowledge.

The points referred to the Commission were grouped under three heads: (*a*) whether tuberculosis in animals is one and the same; (*b*) whether animals and man can be reciprocally infected with it; and (*c*) under what conditions, if at all, transmission of the disease from animals to man takes place and what are the circumstances favourable or unfavourable to such transmission. The present interim report goes far to answer completely the question put in (*a*) and partially the problem presented in (*b*) Concerning (*c*) we must await a subsequent report The commissioners first turned their attention to determining whether the bacillus of bovine tuberculosis is specifically distinct from the bacillus of human tuberculosis. With the view of solving this problem more than 20 strains of tuberculous material from the tuberculous sputum, lungs, glands, and joints of human subjects were employed, the effects produced being compared with those resulting from the employment of different strains of tuberculous material of bovine origin The details of these experiments are held over by the Commission for a subsequent report, but the conclusions are given with a commendable directness which we shall closely follow. Seven of the strains of human origin when introduced into cattle gave rise at once to acute tuberculosis and the development of widespread disease in the various organs, such as the lungs, the spleen, the liver, and the lymphatic glands. In some instances, it is added, the disease was "of remarkable severity." These experiments would seem conclusively to suggest that KOCH and SCHUTZ must have been dealing with strains of tuberculous material of a different type. In this case the contradictory results which have been obtained by different observers are to be explained by slight variations of the effect of the soil on the seed, much in the same way, perhaps, as some persons are immune to a disease at one time and susceptible at another, or resistant to one strain of scarlet fever while highly susceptible to another. This view is rendered probable by the behaviour of the remaining strains of tuberculous material which were made use of by the commissioners. In these the disease was "either limited to the spot where the material was introduced (this occurred in two instances only) or it spread to a variable extent from the seat of inoculation along the lymphatic glands with at most the appearance of a very small amount of tubercle in such organs as the lungs and spleen." But the subsequent history of these cases is extremely instructive and suggestive. When tuberculous material was taken from these slightly affected bovines and introduced into other bovines, or into guinea-pigs from which bovines were subsequently inoculated, such material had up to the time of the report given rise in the case of five of the remaining strains to general tuberculosis of an "intense character" in the bovine.

As regards the identity of the human and bovine disease the commissioners state that after careful comparison they have "found the one, both in its broad general features and in its finer histological details, to be identical with the other," and they have failed to discover any character by which they could distinguish the one from the other. The results of their investigation have indeed been so striking that they have felt it their duty to make them known without further delay. Obviously the commissioners are not yet prepared to answer fully all the problems presented to them, or to estimate the danger to the public health of the consumption of tuberculous milk and meat, but nevertheless they come to this significant conclusion: "that tubercle of human origin can give rise in the bovine animal to tuberculosis identical with ordinary bovine tuberculosis seems to us to show quite clearly that it would be most unwise to frame or modify legislative measures in accordance with the view that human and bovine tubercle bacilli are specifically different from each other, and that the disease caused by the one is a wholly different thing from the disease caused by the other." Few pathologists or epidemiologists will, we imagine, join issue with this conclusion and many will regard this identity of the disease as an adequate basis for more rigorous precautions as regards our domestic milk-supply. We shall, however, await with the greatest interest the further report of the Commission in relation to the measure of the danger incurred by man from the consumption of tuberculous milk and meat. This aspect of the problem will have to be approached largely from an epidemiological and statistical standpoint, albeit there will still be room for much experimental work in connexion with the mammals nearest to man. The commissioners pay a graceful tribute to Sir JAMES BLYTH for his generous assistance in placing his farm at Stanstead at their disposal, and we could wish that tributes of a like nature from science to wealth were more frequently called for. Sir JAMES BLYTH by his munificence has saved the public purse and earned the gratitude of science.

Annotations.

"Ne quid nimis."

METROPOLITAN HOSPITAL SUNDAY FUND.

June 12th will be Hospital Sunday. We publish to day the annual supplement in which we urge the claims of the London hospitals upon the generosity of the public and we may remind the members of the public that although the amount collected for the Hospital Sunday Fund has shown an almost steady increase year by year, yet the amount of sickness and suffering for the relief of which the money of the Fund has to be applied does not seem to lessen and the hospitals are in as much need as ever of the contributions of the charitable. We need not repeat here the reasons why the public should contribute to the Hospital Sunday Fund, for they are laid down in the supplement, but we earnestly hope that despite the growth in the expenses of living which has become so marked of late years the public, both those who are blessed with a superfluity of this world's goods and those who are not, will contribute their sovereigns or their pence towards the aid and succour of their poorer brethren. They should remember that the hospitals enable the medical profession—to whom the rich and poor alike look for succour when ill—to keep their knowledge up to the high level which modern science dictates. Mr. George Herring has again offered to give a donation of 25 per cent. on any sum collected in places of worship up to £100,000, a generous offer which should form a stimulus to others, for it means that every sovereign subscribed to the fund becomes by Mr. Herring's munificence 25*s*.

COMPULSORY MILITARY TRAINING.

IF the majority report of the Royal Commission recently issued on the organisation of the militia and volunteers travels beyond the limits intended to circumscribe the subject of their inquiry the Royal Commissioners had nevertheless the courage to follow it up to what seemed to them to be the only logical conclusion at which they could arrive. The adoption of compulsory military service in this country after the manner of Continental Powers is, it is needless to say, a very big question. It may be neither necessary nor suitable to provide a large army for home defence for an island Power which if it once lost command of the sea would be more at the mercy of its foes by way of famine than by assault. Be this as it may, we do not think that the Royal Commissioners will have done any harm by having aroused public attention to a subject which sooner or later—and the sooner, perhaps, the better—must be thoroughly threshed out and settled. The report, to which there are several dissentients, is accompanied by two volumes of minutes of evidence and a voluminous appendix, so that there is no lack of material for consideration. After pointing out the inability of our present auxiliary forces to defeat an invading army, the main points in the conclusions of the Commission are that the whole able-bodied male population should be trained to arms, the training to be given within one year, with subsequent annual periods of a few weeks' exercise. We venture to doubt whether public opinion will at the present time be prepared to accept the proposal of a one year's conscription. But from a political, industrial, and economic point of view the question of compulsory military service does not concern us. We can only consider it in its medical and hygienic aspects, and in these relations we would refer our readers to a leading article on the subject which appeared on p. 1747 of THE LANCET of Dec. 23rd, 1899. From the physical, moral, and mental side we have no doubt of the beneficial effect that might be expected to ensue from a course of military training and open-air exercise on the youth and young manhood of our population It is not easy, indeed, to overrate the value of some kind of military training. The proof of this being so can be seen by contrasting the appearance of the young and raw recruit on enlistment with what it is soon afterwards or when he has become a soldier. In physique, general bearing, intelligence, and alertness of mind and body the change is always apparent, and the improvement often quite remarkable. And, as regards the class from which his officers are drawn, the physical growth and development of the cadets on joining the military colleges at Woolwich and Sandhurst as compared with these conditions when leaving are sometimes even more striking than in the case of the private soldier.

MOTOR-CARS FOR MEDICAL MEN.

THE *Autocar* has just issued a special number with the above title which all waverers between horses and motors may consult with advantage. The number contains articles written by medical motorists and 15 pages of letters from owners of cars in the profession. Naturally the pleading throughout is of an *ex parte* nature. The experience of many of the writers is small, but it is of interest to get even a small census of the builds of cars employed. The reliability of motors stands in a very different position to-day from that which it held three years ago and may be regarded as established; there is no question as to the enormous saving of time and the leisure earned by driving a car instead of a horse. Our chief concern, therefore, in studying this article is to get a real clue as to the relative economy of the two methods of locomotion. The question of cost is complex and we do not find that the numerous statements afford great help. Most of them are very vague and some of the most detailed are obviously fallacious. If we consider the mere upkeep, the average repairs, the cost of petrol and lubricant, and the heavy expenditure on tyres as set against the ordinary expenses of a stable, we arrive at the following general conclusions. First, that when the mileage is so great that three or more horses have to be maintained there is no question as to the economy of motors even if a reserve motor is kept. Again, if the area of work is small and the necessary mileage is low—say under 12 miles a day—the amount of petrol consumed and the wear of tyres involved are little enough to make the car compare favourably with the horse and trap. The doubtful cases are the practices which demand two or occasionally three horses. But this estimate of cost does not cover certain points of importance. First, there is the large capital outlay, the interest on which must be considered. No one can yet give us the probable life of a motor or any approximate estimate of its depreciation. We know now what the working life of a bicycle is; regularly worked it lasts in smart condition for about four years. Assuming (which we are far from doing) that the general type of motors is approaching the finality of model which the bicycle acquired some seven years ago, can we believe that the economical life of a motor is likely to be much longer? It probably will be longer on account of its greater strength of frames and general structure, but the depreciation must always be far greater than that of horses and carriages. Next, though the reserve of pace in a motor is very great, the reserve of carrying power is much smaller than that of a horse and carriage. But when we begin to deal with motors which can climb steep hills with four passengers, or those equipped with removeable closed bodies, the price soon runs up. A good car with tonneau and moveable omnibus top for work in a hilly country will cost close on £400, and the extra weight soon tells on the bills for petrol and tyres. We do not also believe profoundly in the cheap lad as chauffeur. There is the further difficulty of the cost of hire of a car during repairs or the renovation of paint-work and parts which all carriages must undergo. Having decided on the advantages of a car, the would-be purchaser will be interested to learn what car the practitioners drive who have contributed to the *Autocar*. By some 33 letters it appears that the cars are nearly all small and of low horse power; only three steamers are represented (one an American "White" and two the now popular Turner-Milsoe build of Wolverhampton). There are two each of the little 4½ h.p. Swift and the 10 h.p. Clement, two small De Dions, two Oldsmobile, and two Cadillac. There is no other car repeated in the list except one notable exception; it is remarkable how the Argyll seems to appeal to the medical profession. We find no less than seven. The choice is unquestionably a good one, for the Argyll cars are very simple, very strong in frame, suitable for the hardest work, and have thoroughly good engines, not too high in power. The frame and gearing are built in Glasgow by the Hozier Co., but the engines are foreign. Among low-priced cars the little Cadillacs hold excellent records for reliability and hill-climbing power, but they are light in the frames for English taste. We should have expected more information on the important subject of tyres; hardly any advice upon the matter is given, but the opinion clearly stated by Mr. Moiisson we believe is sound, that is to have pneumatic, not solid, tyres, but to have them extra heavy and strong; "Overtyre your car at first," he says, "and you will never regret it."

SOME MEDICAL FORMULÆ FROM AN EGYPTIAN PAPYRUS.

All students of the early history of medicine know how intimately it was connected with magic and shamanistic practices. A supreme instance of this mingling is afforded by the "Demotic Magical Papyrus," just published by Mr. F. Ll. Griffith and Mr. Herbert Thompson.[1] Unfortunately for science, whilst containing a multiplicity of magic, it presents but a modicum of medicine, and that of a very inferior kind, but such as it is it deserves mention in a modern medical journal. The papyrus is of the third century A.D. and is in comparatively good preservation, a matter of importance, for our knowledge at present of the Demotic script is so slight that unless manuscripts engrossed in it are very clear they cannot be correctly interpreted. Its 29 chapters are almost all devoted to incantations and invocations of the most puerile nature, the majority of them having erotic objects in view. Divination has its place and some incantations are for the curing of bites of poisonous reptiles and dogs. The first items of a medical character occur in the twenty-fourth chapter among formulæ for "drugging a person." The substances recommended for this purpose are: scammony (convolvulus) root, one drachm; opium, one drachm; mixed with milk. A second formula advises mandragora root, one ounce; liquorice, one ounce; hyoscyamus (henbane), one ounce; ivy, one ounce; to be given mixed in wine. The author appears to have apprehended an error in selecting the ivy leaves and therefore appends a botanical description of the plant, saying, "Ivy—it grows in gardens, its leaf is divided into three lobes like a vine leaf, its (leaf) is one palm in measurement, its blossom like silver, another says gold." This last statement may have arisen from the reference being to some very ancient Egyptian work, for in antiquity silver was called "white gold." One recipe in column 9 of the back of the papyrus is a recommended cure for gout. Its contents are one measure of euphorbia, a half measure of pepper, one measure of pyrethrum, probably an umbellifer, burning to the taste, one measure of adarces, and one of sulphur to be pounded together, mixed with wine and oil and applied to the part of the patient that was painful. Mr. Griffith points out that four of these ingredients occur in a prescription for gout provided by Alexander of Tralles—viz., spurge, pepper, *πύρεθρον*, and *ἀδάρκης*. Dioscorides also mentions pyrethrum. Column 2 contains remedies for a sprained foot; one of them consisted of garlic, frankincense, and oil, macerated together, used as an ointment, and then the foot was to be bathed with cold water. Some paragraphs are occupied with diseases of the eye, maladies always sadly prevalent in Egypt. One, after giving various verbal spells, prescribes a collyrium of oil, salt, and nasturtium seed. The Coptic word for this has, in its Sahidic dialect form, been identified with the *κάρδαμον* of Dioscorides. In all this class of papyri the names of the demons, deities, or spirits invoked are generally the merest gibberish, but one in this document, Eriskhigal, is evidently the ancient Babylonian Persephone—Erish-ki-gal—a name only recently recovered from cuneiform inscriptions but which it is now evident was at one time known in Græco-Roman Egypt.

FRACTURE OF THE SCAPHOID BONE.

One of the results of skiagraphy has been to reveal fractures which, in consequence of their position, were not previously diagnosed, the injury being regarded as a sprain. In a paper in the *Boston Medical and Surgical Journal* of April 7th Dr. E. A. Codman expresses the opinion that in the majority of cases diagnosed as sprains in which recovery does not promptly take place there is a fracture. Among the commonest of unrecognised fractures is, he thinks, fracture of the scaphoid bone of the wrist. The following is a typical example. A youth, aged 20 years, injured his wrist in playing football. Though no crepitus was obtained splints were applied and worn for several days. The swelling and tenderness subsided to a certain extent. The joint remained sore and movements beyond a slight angle were very painful. About six weeks after the injury the patient consulted Dr. Codman who made a diagnosis of fracture of the scaphoid bone and confirmed it by radiography. As he thought it was too late to attempt to obtain union he kept the wrist in splints for only a fortnight and then had it massaged. It improved considerably but it still remained somewhat swollen and was painful on extreme movements. The patient could no longer play football and he frequently hurt the wrist in jostling his fellow students. During two years there was only slight improvement and at the end of this time the wrist could not be extended beyond an angle of 25° without great pain; flexion was less painful but in the extreme position almost as painful as extension. There was marked tenderness of the scaphoid bone which was best obtained by adducting the wrist and pressing with the thumb in front of the styloid process of the radius. About 40 cases of fracture of the scaphoid bone have been observed at the Massachusetts General Hospital, so that the injury appears to be common. Dr. Codman gives the following diagnostic points. There is no deformity, ecchymosis, crepitus, or abnormal mobility. There are localised swelling and tenderness in the region of the scaphoid bone—i.e., in the radial part of the wrist-joint,—limitation of active movements, and sharp pain on attempts at passive movement, the joint protecting itself by muscular spasm. The diagnosis should be confirmed by skiagraphy, the best method being to take an antero-posterior view during adduction. In most of the cases union does not take place and in those in which it does the callus is so extensive as to interfere with the movements of the wrist. The treatment consists in endeavouring to obtain union by fixing the joint for at least three weeks. When union has not taken place and a considerable time has elapsed, if the condition of the wrist interferes with the patient's occupation, Dr. Codman recommends excision of the proximal part of the bone but he has never performed the operation. But in two cases of compound dislocation of the wrist in which the scaphoid was broken and its proximal half excised the patients had afterwards fairly good wrists.

---

A HUNDRED AND FIVE.

THERE has been a good deal of scepticism as to reported cases of people living for a century, but some that are heard of from time to time seem to be well authenticated. About three months ago the master of Blackburn workhouse took pains to verify the age of a man who had been 11 years in the workhouse and who died at the age of 105 years. He was cheerful, active, and industrious until a few months before his death and could read without spectacles till the last, and for the 11 years of his stay in the house he had acted as "ganger of the bedmakers." He was a snuff-taker and habitual smoker and "was not averse to a glass of beer." Perhaps those who take extreme views of the injury done by smoking, snuff-taking, and by even what is called a moderate use of alcoholic beverages may think that if he had abstained from them altogether he might have lived 30 or 40 years longer. That, however, is an unprovable proposition. The other facts of the case, which there seems no reason to doubt from the care taken as to the inquiry, go to show that heredity, independent of habits, has a large share in the causation of longevity, for it is stated that this old gentleman's mother lived to 105 and that he had a sister aged 102 who was killed at Preston a few years ago.

SCHOOLS AND INFECTIOUS CONDITIONS.

A REPORT has been presented to the Gloucestershire education committee by Dr. J. Middleton Martin, county medical officer of health, dealing with the importance of a systematic medical examination of children attending elementary schools to discover the existence of infectious conditions, whether acute specific diseases, infectious skin lesions, or parasites. This report points out the danger of school attendance in spreading these conditions—e.g., in one school alone 23 children out of a total of 65 were absent owing to ringworm, contracted apparently at the school—and since attendance at school is compulsory and by a recent Education Act the education committee is responsible for all children during the hours of school attendance, it is naturally of great importance that the conditions to which children are subjected at school should be as safe as possible. It is obvious that if effective action is taken the prevalence of such infectious conditions can be reduced to, and maintained at, a minimum and that therefore the spread of epidemics can be limited and thus many lives be saved. The county medical officer was invited by the committee to prepare a scheme dealing with one section of the county, the Stroud area being suggested. Naturally, since teachers are not in a position to form an opinion upon the infectious state of a child, to determine which in some cases may require a microscopical or bacteriological examination, the only practical method of dealing with the matter is to provide for a systematic medical examination of all the children. Dr. Martin has proposed a scheme, of which full details are given in the report, by which such an examination can be effected. He suggests that the simplest and most effective arrangement would be for the medical man nearest to a particular school to be appointed medical officer for that school and he has grouped the various schools in the Stroud district for this purpose. At the opening of schools the medical officer would be required to attend and to examine the children, carefully inspecting any child presenting a suspicious appearance and excluding all whom he might find suffering from any infectious or contagious conditions. The parents' attention would then be drawn to the reason for such exclusion, and the child would not be allowed to attend until a certificate of freedom from the condition was supplied by the family medical man or the school medical officer. In cases of notifiable disease, of course, the medical officer of health of the district would be informed. In cases of infectious or suspicious conditions arising during term time the child should be sent to the school medical officer, or, if advisable, the medical officer should be asked to see the child at home. In his report Dr. Martin suggests a graduated scale of payment of the medical officers and estimates the total cost for the Stroud district, comprising an average attendance of 6200 scholars, at £150 a year. He calculates that the total cost of such a scheme for the whole county would be £1500, while if as a result the average attendance was increased only 2 per cent. the gain to the county would be £1600, a rise of 1 per cent. being worth £800 a year. The scale of fees suggested is briefly as follows. For inspection of a school of which the average attendance is 100 or under, one guinea; from 100 to 200, one and a half guineas; from 200 to 300, two guineas; from 300 to 400, two and a half guineas; while for subsequent visits to examine small groups of children of under ten in number a fee of half a guinea per visit, or if over ten in number, one guinea, while for each child seen at the medical officer's house there would be a fee of half a crown, or if seen at the child's own home, five shillings. It is gratifying to notice that the Gloucestershire education committee has decided to carry out this scheme for the Stroud district, and the results of this pioneer effort will be watched with very great interest, as it is certainly a move in the right direction. It is, of course, probable that the details of the scheme may require modification, but there can be little doubt that the principle is a good one.

DIABETES INSIPIDUS.

AT the meeting of the Association of American Physicians held on May 10th some interesting observations on diabetes insipidus were recorded. Dr. Thomas B. Futcher of Baltimore described and analysed all the cases which have occurred at the Johns Hopkins Hospital since its foundation. There were altogether only seven cases—six in the hospital and one in the dispensary—so that the disease is a comparatively rare one. Out of the seven patients four had had syphilis and all of these improved after the administration of iodide of potassium. Heredity seems to be a factor of some importance in the production of the disease, as the observation of one family for four generations has shown that among 90 members more than 1 in 5 have suffered from the disease. The affection is more common in males than in females and is most frequent between 30 and 40 years of age. Even in a case in which no syphilitic history was obtained there was marked improvement after the administration of iodide of potassium with a gain of nearly 20 pounds in weight. Dr. W. H. Thomson of New York recorded a case in which miliary tuberculosis was found post mortem with tubercles on the floor of the fourth ventricle. Dr. James Tyson of Philadelphia had also found iodide of potassium of great benefit even when a syphilitic history was not obtained. Dr. Abraham Jacobi of New York was of opinion that among children diabetes insipidus was not a rare disease. He had found it in association with chorea and some convulsive diseases, and also after severe whooping-cough. He had also found it in cases of hereditary syphilis. He agreed with the usefulness of iodide of potassium, but had also found ergot of service in the disease.

THE METROPOLITAN STREET AMBULANCE ASSOCIATION.

As will be seen by a letter from Dr. A. W. James, the honorary secretary of the above association, the membership has increased so rapidly that certain expenses have been incurred which there are no funds to meet. No subscriptions are asked for from members, so that the association is entirely dependent upon donations for funds to meet whatever expenses may be incurred. The work is carried on as economically as possible and the local secretaries, who number 110, give their time and trouble gratuitously. The London County Council has, as already noted in our columns, received a deputation from the association and has appointed a subcommittee to consider the question. Of the need of an efficient ambulance service for the unwieldy collection of towns which is collectively known by the name of London there can be no doubt and we earnestly hope that the small sum required—namely, between £70 and £80—will be raised.

THE ROYAL COLLEGE OF SCIENCE AND MEDICAL EDUCATION.

IT is announced that the Board of Education has appointed a departmental committee to inquire into the present working of the Royal College of Science. The reference to the committee is a wide one, since it is instructed to consider in what manner the staff, together with the buildings and appliances now in occupation or in course of construction, may be utilised to the fullest extent for the promotion of higher scientific studies in connexion with the work of existing or projected institutions for instruction of the same character in the metropolis or elsewhere; and to report on any changes which may be desirable in order to carry out such recommendations as it may make. It is seldom that any existing institution is provided with such a liberal extension of premises as that which will shortly be given to the Royal College of Science. The magnificent site occupying the whole length of the road opposite the University of London (formerly the Imperial Institute) is rapidly being covered by a splendid block of buildings destined to form additional quarters for the Royal College of Science. Rumour at one time had it that this new building was to be devoted to chemistry and physics, while natural history and allied subjects took entire possession of the original building standing a little further south-east. There were not wanting those who stated that the College required all this additional space to carry out successfully its existing work. The appointment of the above committee would seem, however, to indicate that those in authority regard this as a fitting opportunity to consider whether it may be possible to widen the scope of the work of the Royal College of Science. No more suitable time could have been chosen to consider whether it is possible for the Royal College of Science to render any assistance in the preliminary scientific education of medical students. The various authorities who are responsible for the education of medical students have for some time regarded the conditions of that preliminary scientific study as unsatisfactory. The reconstituted University of London has adopted a scheme which is destined to effect considerable improvements in these conditions and it is certain that this scheme must officially or unofficially come under the notice of the committee recently appointed by the Board of Education. It is much to be hoped that those who are interested in the proposed changes in medical education will take steps to be heard by the committee, and that the way in which the staff, building, and appliances of the Royal College of Science may be utilised for the promotion of higher scientific studies in connexion with the projected Institute of Medical Sciences of the University of London will be thoroughly thought out and clearly impressed upon its members. It will not be forgotten that in Huxley's time an attempt was made to make use of the scientific courses at the College for the purposes of preliminary medical education and it will no doubt be pointed out that notwithstanding Huxley's active sympathy and the cordial approval of the medical schools the experiment was somewhat of a dismal failure. Nor could any more hopeful result be prophesied now were it not for the proposal of the University of London to found an Institute of Medical Sciences at South Kensington within a stone's throw of the new buildings of the Royal College of Science. If it is found possible in any way for some of the resources of the Royal College of Science to be so used as to assist the University of London in forming a centre of education in preliminary and intermediate medical subjects a very great benefit would be conferred upon medical education in London. Nor would the educational benefits be confined to the medical students whom the Royal College of Science received within its walls. It is agreed on all hands that the admixture of different classes of students in our colleges is of the greatest benefit to education in its widest sense. The *personnel* of the students at the Royal College of Science would undoubtedly be benefited by the addition of a proportion of men preparing to enter the medical profession. With so many obvious advantages to be gained it ought not to be impossible to devise a scheme acceptable to the Royal College of Science, the University of London, and teachers in the medical schools.

PERSIAN MEDICINE.

PERSIA, whether regarded from the point of view of its history, its climate, its inhabitants, or its political importance, is a most interesting and delightful country. It is quite unspoilt by modern innovations, it is free from the worries of fiscal problems, passive resisters, questions in Parliament, and educational and religious difficulties, while its fertility, given a good water-supply, is inexhaustible. Altogether, its social condition is much the same as was the case in the days of the great Shah Abbas, who lived in the time of our Queen Elizabeth, and this being the case Persian medical science is still in a primitive condition. Our contemporary, the *Manchester Courier*, some weeks ago published two very remarkable articles by Mr. H. R. Sykes upon Modern Medical and Surgical Treatment in Persia. Mr. Sykes derived his information from Miss Bird who was formerly superintendent of the Kerman Mission Hospital. Kerman is one of the most important towns in Persia, being situated in latitude 30° 20′ N. and longitude 57° 2′ E., at the conjunction of several important trade routes some 200 miles from Bandar Abbas on the Persian Gulf which acts as its port. Through it flows trade between the Gulf, Northern Persia, Central Asia, and India, so that a hospital there has a large *clientèle* suffering from various diseases. Persian medicine is founded upon the practice of a Greek medical man who accompanied Alexander the Great in his Indian expedition and some of the more learned of the Persian hakims profess the teaching of Ibn Sina, better known to European readers by the Westernised form Avicenna, who was born at Bokhara in 980 A.D. Diagnosis is reduced to a simplicity which may well make the Western medical man turn green with envy. All diseases are either cold or hot. A hot disease requires a cold medicine and a cold disease a hot medicine. If the hakim is in doubt he first tries one remedy and then if that does not succeed he tries the other. Sometimes the patient gets well, in which case the hakim takes the credit and the fee, which latter is often in kind. As an instance of this, one European medical man of our acquaintance after restoring to health a patient seriously ill with some sort of toxic fever, by means of 15 grains of calomel, was rewarded by a pair of socks. If the patient dies the hakim says that it is God's will. Surgery is in as crude a condition as medicine; fractures are treated by splints made of paper stiffened with white of egg but the limb is frequently bandaged so tightly that gangrene sets in. In Northern Persia, at any rate, syphilis is extremely frequent and the medical man whom we have previously mentioned frequently saw villages of which nearly the whole population showed syphilis in one form or another. Diseases of the eye, as throughout the East, are very common, more especially ophthalmia, the liability to which is increased by the dust and the glare. With trained medical men Persia might become a health resort of great value. There are many mineral springs, and in Northern Persia the district round the lake of Urmi possesses most valuable thermal waters. The lake of Urmi itself could be used for the same affections as those for which the waters of Droitwich are used in this country for it is a saturated solution of salt. A man bathing in it is quite unable to swim, for all that he can do is to lie on his back on the top of the water or to sit in it with his arms round his knees. A marsh surrounds the lake made up of sulphurous mud and at intervals [illegible] reputation [illegible] the skin. [illegible] be found who have had a European training but as a rule Western medicine is only to be found at the various missions. The American Presbyterian mission does excellent medical work at Urmi and the French Roman Catholic mission keeps up a hospital where the nursing is done by the sisters of St. Vincent de Paul, but, so far as we know, no medical man is attached to this mission. The Church Missionary Society also does useful work from a medical point of view at Julfa, near Ispahan (not the Julfa on the Araxes which is little more than a telegraph station), but on the whole medical science in Persia as it affects the natives is but little touched by Western ideas and as a rule the Persian hakim of to-day is the same as he is depicted in Morier's immortal work, "Hadji Baba."

THE POWER OF PRISONERS TO INJURE THEMSELVES.

A SOMEWHAT mysterious case was recently inquired into by Mr. Garrett at the South-Western police court without any definite conclusion being arrived at. A woman who undoubtedly had been put into a cell overnight very drunk was brought before the magistrate with marks upon her face and neck which, according to medical evidence, were consistent with her having been burnt with carbolic acid. A bottle which contained, or which had contained, carbolic acid was [illegible] been found in her cell and [illegible] d for, the police stating th[illegible]ched when she was put in the cell. The woman stoutly maintained that the burns had been caused by a member of the police at the station who had deliberately thrown the acid over her, but she declined to identify any particular man saying that as her glasses had been taken away she had been unable to see his features. In the circumstances Mr. Garrett ordered that the defendant should pay the fee of the medical man summoned to attend her and requested the police to investigate the matter. Upon such evidence no one would willingly impute to a constable the dastardly outrage charged by the woman, but the matter is certainly [illegible] quires considerable attention on the part [illegible] rities. That a drunken woman should be [illegible] a bottle, whether of carbolic acid or of anything else, when lock[illegible] to the vigilance [illegible]ations. Concealme[illegible]mes to serious results, and the cases of Whitaker Wright and another convicted prisoner at the Old Bailey, both of whom committed suicide, are of recent occurrence. These two prisoners took their own lives in order to avoid long terms of penal servitude, but suicides in police cells are by no means uncommon and the inebriate or the person of ill-balanced mind charged with a minor offence is at least as likely to try to make away with himself as the malefactor who has deliberately committed a more serious breach of the law.

THE DISTRIBUTION OF PLAGUE.

As regards the Transvaal, Lord Milner, in a telegram to the Colonial Office received on May 28th, states that the plague return for the week ending on that date was as follows. Total number of fresh cases reported since May 21st, 5, all coloured persons. Of previous cases 5 have been found not to be plague, making the present total of suspected and proved cases 140—viz.; 24 white and 116 coloured persons. The total number of deaths reported since May 21st is 3, all coloured persons. As regards Hong-Kong, a telegram from the Acting Governor received at the Colonial Office on May 31st states that for the week ending May 28th there were 27 cases of plague and 27 deaths from the disease. A telegram from the Acting Governor of the Mauritius received at the Colonial Office on May 27th says that for the week ending on that date there were three deaths from plague.

PRIMARY CEREBRAL ACTINOMYCOSIS DIAGNOSED BY LUMBAR PUNCTURE.

AT the meeting of the Société Médicale des Hôpitaux of Paris on May 13th M. Enriquez and M. Sicard described the following case of actinomycosis which is remarkable not only on account of the rarity of the disease in the brain but also because of the establishment of the diagnosis by lumbar puncture. A groom, aged 43 years, was admitted to hospital in July, 1898, with all the signs of cerebral tumour in the cortex of the left hemisphere. There were attacks of Jacksonian epilepsy, headache, visual troubles, and vertigo. Although he denied having had syphilis mercury and iodide were given energetically but without result. The symptoms increased in severity, walking became more and more difficult, and double optic neuritis developed. Trephining without incision of the dura mater was performed. As in almost all their cases of cerebral tumour M. Enriquez and M. Sicard found that the operation produced amelioration of the symptoms—vertigo, headache, and nausea, and above all of the stasis of the optic discs. But three weeks later the patient relapsed and lumbar puncture was tentatively performed in order to diminish the hydrocephalic tension. Cloudy fluid was obtained. At this time cytological examination of fluids was unknown. Microscopic examination of the deposit obtained after allowing the fluid to stand revealed actinomycetes. The patient was in the habit of chewing straw, but neither in the mouth nor elsewhere could the portal of entry of the fungus be discovered. A meningocele formed in the cranial wound and at its summit suppuration took place. In the pus characteristic granules with central mycelium and peripheral club shaped bodies formed. Increasing doses of iodide of potassium were given but the patient died at the end of a fortnight from diffuse staphylococcic meningitis. The duration of the disease was less than eight months. In the fluid obtained by a second lumbar puncture two days before death the [illegible]occi. The necropsy [illegible]. In the left fronto-[illegible]mour, purulent at the periphery. It communicated by a narrow opening with the left lateral ventricle. Neither in the tumour nor in the pus could actinomycetes be found, only staphylococci. The other viscera were normal. The absence of actinomycetes from the tissues examined after death is easily explained. M. Poncet has shown that after secondary infection with pyogenic microbes the fungus disappears from the affected parts. M. Enriquez and M. Sicard could find on record only one other case of primary cerebral tumour due to actinomycetes. In it the actinomycosis was recognised only at the necropsy. The tumour was situated in the position of the third ventricle. The portal of entry was in this case also impossible to find. The patient died comatose without secondary infection about a year after the onset of symptoms. On the other hand, secondary cerebral actinomycosis is well recognised. Out of 19 cases referred to in the classical treatise of Poncet and Bérard cranio-cerebral actinomycosis was due to extension from a cervico-facial lesion in eight and due to metastasis, almost always from pleuro-pulmonary lesions, in 11. This case again shows the value of lumbar puncture in diagnosis—a subject to which we have referred recently. The setting free of the fungus in the cerebro-spinal fluid was probably due to penetration into the dilated lateral ventricle from the tumour. M. Poncet finds that actinomycosis of the nervous system is invariably fatal. The largest doses of iodide are powerless to arrest the disease and the patients do not live beyond some months.

THE FIFTEENTH INTERNATIONAL CONGRESS OF MEDICINE.

A MEETING of the National Committee for Great Britain and Ireland was recently held, Dr. F. W. Pavy being in the chair, and Sir William S. Church, Sir Dyce Duckworth, Mr. Reginald Harrison, and others being present. It was resolved, in view of the confusion and disorder attending the last assemblage of the Congress—attributable, it is considered, to the deviation from former procedure in admitting as members of the Congress others than medical and scientific men—that the attention of those intrusted with the organisation of the forthcoming Congress at Lisbon should be called to the matter. This resolution was forwarded to the President and Secretary-General of the fifteenth Congress which will meet at Lisbon in April, 1906, and the rules just issued show that the qualifications of members are as strictly limited as they were at Paris in 1900. The recommendations of the subcommittee as to the future constitution of the National Committee were approved and it was decided that the committee should consist of a president and two secretaries who should invite the coöperation of (1) His Majesty's chief medical advisers in the Navy, the Army, the Indian Army, and the Lunacy and the Local Government Boards; (2) the Presidents for the time being of each medical corporation in the United Kingdom; (3) the President of the General Medical Council; (4) a professor of the faculty of medicine from each University; (5) the President for the time being of the Royal Medical and Chirurgical Society of London, of the Royal Academy of Medicine in Ireland, and of the Medico-Chirurgical Society of Edinburgh; (6) the President for the time being of the Incorporated Society of Medical Officers of Health; (7) a representative of the National Medical Press Association; (8) eight persons practising medicine and surgery in England (including Wales), four general practitioners from Scotland, and four general practitioners from Ireland; and (9) such other persons as it may be found desirable from time to time to invite to the National Committee. Dr. Pavy was asked to continue in the office of President and Mr. D'Arcy Power as secretary. Dr. Horton-Smith regretted that he was unable to continue to act as secretary. Dr. Clive Riviere was nominated to act in his place and a cordial vote of thanks was tendered to Dr. Horton-Smith for the valuable services he had rendered to the National Committee during his tenure of office. It was proposed by Dr. J. F. Sutherland that, in order to allay the feelings of irritation and disappointment rankling in the minds of those who attended the Madrid Congress, and to reassure these and others who may contemplate attending the Lisbon Congress, the honorary secretaries should be instructed to send a note to THE LANCET and the *British Medical Journal* to the effect that the British National Committee intends to supervise the comfort and convenience of congressists. The committee hopes to prevent or to reduce to a minimum at the Lisbon meeting the annoyance, discomfort, and disappointment experienced in Madrid in regard to travelling facilities, lodging accommodation, and so on, and to attain this end it is desirable to have a local British committee to keep in touch with the executive of the Lisbon committee. The proceedings terminated with a vote of thanks to the Medical Society for its kindness in putting the society's rooms at the disposal of the British National Committee.

THE INFANT ORPHAN ASYLUM AT WANSTEAD.

IN another column of our present issue we publish two important letters relative to precautions against the occurrence of infection among the children in the Infant Orphan Asylum at Wanstead. We think that many friends of that long-established institution will regret that the committee has adopted a course so incompatible with the expressed opinions of the medical staff. In view of the universal liability of young children to scarlet fever, measles, and whooping-cough and the havoc that has often been worked by outbreaks of contagious eye disease among children in Poor-law institutions, no effort should be spared in the early detection and isolation of such cases. A number of schools, both public and private, recognise this fact and make provision accordingly but the committee of the Orphan Asylum, where many of the children are of tender years, not only declines to provide an isolation building but has dismissed the staff of trained nurses.

THE FORD-PALLISER DRINKING TANK.

UNDER the heading of "The Services" in THE LANCET of May 21st, p. 1458, we briefly referred to some inventions of medical interest which were shown at Bisley on May 17th, one of them being a water cart with appliances for rapidly boiling water in large quantities, thus minimising the risks of infection with enteric fever. The essential feature of this water-cart, which has been called by its designers the Ford-Palliser (Anti-enteric) drinking tank, is a tubular boiler-tank heated by ordinary paraffin oil. In this apparatus 50 gallons of water can be boiled in an hour while the cart is in motion, the tank being kept level by means of a gimballed arrangement. A second tank with interior cells containing a solution of saltpetre is connected with the boiler and is used for cooling purposes. Water which has been exposed to any kind of microbic or organic contamination is well known to be improved immensely for drinking purposes by mere boiling. If therefore it is found practicable under the conditions of a campaign to boil water rapidly whilst the cart is in motion and to distribute this water by the ordinary water carts to the troops in the field, a great advance will almost certainly have been made in protecting the men from enteric fever. Among those who witnessed the exhibition at Bisley were Lieutenant-Colonel A. M. Davies, from the Army Medical Headquarters staff, Major T. C. McCulloch, R.A.M.C., Colonel Robinson, officer commanding the Royal Army Medical Corps Depôt, Aldershot, Lieutenant-Colonel

C. R. Crosse, secretary of the National Rifle Association, Count von Schulenburg, German military attaché, and a representative of the United States Embassy. Major Palliser, late 7th Hussars and Canadian Militia, and Lieutenant-Colonel R. W. Ford, D.S.O., R.A.M.C., were also present, the appliances having been constructed under their joint advice by Cammell, Laird, and Co. of Sheffield and the Albion Lamp Company.

THERE will be found below the plain and unvarnished tale of the proceedings at the Central Midwives Board from the pen of Dr. W. J. Sinclair, a member of the Board and one of our foremost authorities on obstetrics, gynæcology, and education in these subjects.

THE prize distribution at the medical school of St. Thomas's Hospital will be held in the Governors' Hall of the hospital on Friday, June 24th, at 3 P.M. Sir Thomas Barlow, Bart., K.C.V.O., M.D. Lond., will give an address and a garden party will follow in the grounds.

THE commemoration day proceedings of Livingstone College, Leyton, will take place on June 9th. Professor G. Sims Woodhead will preside at a meeting at 3.30 P.M. in the grounds of the College and will formally open the new laboratory which has been arranged in the College.

THE Bolingbroke lecture of the South-West London Medical Society will be delivered on Thursday, June 9th, by Dr. W. H. Allchin on Some Special Features of Diseases of the Colon, at the Municipal Buildings, Lavender-hill, at 8.45 P.M.

CENTRAL MIDWIVES BOARD.

BY W. J. SINCLAIR, M.D. ABERD.

IT will be satisfactory to many readers of THE LANCET to learn that at the meeting of this Board on Thursday, May 26th, a motion was carried to the effect "that reporters of the recognised medical and nursing journals be invited to attend the meetings of the Central Midwives Board." But for the adoption of this motion I should have felt compelled to raise the veil which has so long concealed proceedings affecting so many important interests and to assume the duties of descriptive writer until relieved by professional reporters from the self-imposed but ungrateful task. Now that reporters are to be admitted it seems to me to be sufficient to state, with your permission, my estimate of the existing position of affairs, while explaining some facts and recent incidents which have produced the present situation. In future your readers interested in the administration of the Midwives Act will be able to follow events by the perusal of what they can confidently assume to be incontrovertibly accurate and unbiased reports of proceedings.

The "Midwives Act, 1902," was a sadly defective piece of legislative work. It incorporated in an Act of Parliament the policy of the Midwives Institute as distinct from, and even in opposition to, the interests of the medical profession and, as I *strongly believe*, the *interests of the* working-class public of England and Wales. The amendments suggested by the medical profession in Great Britain could be ignored by the sponsors of the Bill, while for reasons, transparently clear at the time of the final Parliamentary struggle, the opposition of the Irish Members was weakened by illusory and temporary concessions to the Irish schools of midwifery.

One of the most obvious defects in the Act, which at the same time clearly revealed the influences at work, was the constitution of the Central Midwives Board created to administer the Act. The Board proposed in the Bill of 1900 would have been representative, strong, and efficient; the most zealous partisan supporter of the Act of 1902 could hardly say the same of the now existing Board. This *Board, created to control purely medical affairs*, was so constituted that three at least of its members must be non-medical women, and of the total of nine members five might not belong to the medical profession. For purposes of representation the Incorporated Midwives Institute was placed on a footing of equality with the Royal College of Physicians. The Act contains provisions which imply the most tender solicitude for the midwife; it is ominously silent where the interests of the medical profession are concerned. The midwife, having made her own arrangements with her client, is required to send for medical assistance in certain contingencies, but there is not a word about the remuneration of the medical practitioner who responds to the summons and comes to the rescue. Contrast this with the explicit enactment with regard to legal expenses incurred in the administration of the Act (Clause 15). Again, the authors and sponsors of the Bill obviously contemplated that the Central Midwives Board should consist of merely a London coterie, for there is no provision for the payment of expenses incurred by members, as in the case of the General Medical Council, and no regulations with regard to meetings of the Board are even hinted at. Consequently the two country members must submit to mere harassment or fail to perform the duties which they have undertaken. They are required to attend once a month or oftener meetings of the drawing-room type, with afternoon tea, for a short time after lunch, to sacrifice a day's work when called upon, and to pay all the contingent expenses. It may be objected that these are paltry domestic details any reference to which should be beneath the notice of a member of the Board. I hold a different opinion, else I would not mention them. They seem to me to be of the essence of the efficiency of a board created to administer an Act of Parliament affecting the whole of England and Wales, and I maintain that the proceedings of a statutory board ought to be arranged for and conducted in a manner adequate to the dignity of its origin. When the Board thus constituted commenced to frame rules and regulations for midwives the policy underlying the Act soon became evident. The fee for the enrolment of certain classes of midwives was fixed at the paltry sum of 10*s.* and the fee for examination at one guinea. This decision was certainly in the spirit and partly in compliance with the letter of the Act, but it should be remembered in judging Act or rules that these sums included the total expense of obtaining a privileged position which was to secure special advantages *for earning a professional income.*

Let us now look for some of the evidence of a policy contained in certain rules which were framed by the majority of the Board, even if some of them had to be greatly modified or abandoned before the completed rules were forwarded to the Privy Council for approval. They refused to sanction any rule requiring pupil midwives to prove the possession of some definite minimum standard of common school education, fixing any minimum period for training, specifying the minimum number of lectures or lessons comprised in a course of systematic instruction, or giving clear and exact instructions with regard to the contingencies which would demand an appeal for medical assistance during parturition, or in the course of the puerperium. On this last head the matter was to be left to the judgment of the midwife. She was to send for a medical practitioner only when in her opinion the progress of the woman or child was "not satisfactory." Under such loosely framed regulations it would have been next to impossible to make even the most ignorant and negligent midwife answerable for her conduct. On the other hand, some regulations originally framed to magnify the office of midwife were definite enough. She was, *for* example, required to baptise feeble babies in certain events, and she was always to produce conjunctivitis by irritants introduced even before complete birth as a prophylaxis against gonorrhœal ophthalmia. Several of the worst defects in the rules were remedied owing to the acceptance by the Privy Council of suggestions embodied in a "minority report" signed exclusively by medical members of the Board. But still the rules are stamped with the policy of the Midwives Institute; it is to be made cheap and easy for a humble and illiterate class of female persons to become midwives when so disposed; and they are to be relieved, as far as a sympathetic and benevolent interpretation of the Act will permit, from irksome restrictions inserted in the interests of mere child-bearing women of the working classes.

Owing to an accidental interruption at this stage of my letter I have had the timely opportunity of reading in THE LANCET of to-day (May 28th, p. 1543) a concise report of the proceedings of the "Association for Promoting the Training and Supply of Midwives"; kindly permit me the liberty of making short quotations from this instructive report: "The chair was taken by Miss Wilson, president of the Midwives Institute and member of the Central Midwives Board." "Free or assisted training was given by the association." "Reference was made to the training home at East Ham in connexion with the Plaistow Maternity Charity started by the association last year." "The sum of £1000 would train 50 midwives." This report is to me a curious revelation of fact explaining the antagonism of principles in the Central Midwives Board which has hitherto been to me only a distressing phenomenon—on the one hand, the benevolence of a certain largely non-medical contingent towards illiteracy and inefficiency generally; on the other, the futile struggle of a medical minority to raise the standard of education so as to secure a better quality of midwife in the future. During the long agitation to obtain an Act of Parliament for the education, registration, and medical supervision of midwives, who ever heard a complaint about the lack of women ready to assume the name and functions of a midwife? Every argument in favour of every Bill was founded tacitly or explicitly on a promise to eradicate forever the ignorance and consequent incompetence which were the roots of all the worst scandals arising from the practice of midwives. But the policy and methods of the Midwives Institute do not possess even the germs of progress. What good to the community can come from encouraging a class of women who develop a thoughtful turn of mind only owing to their inability to read? We may well despair if the midwife of the future is to be turned out in 14 weeks at the average cost of £20 a head.

Coming now to the present situation, as far as the actual proceedings of the Central Midwives Board are concerned, it appears to me that the first question demanding attention and solution is the dispute between the Dublin lying-in hospitals and the Central Midwives Board. There are two points at issue: (1) the efficiency of the practical teaching of pupil midwives narrowed down to a question as to the number of patients to be personally and exclusively delivered by the individual pupil before she can receive certain certificates; and (2) the number of days after labour during which the pupil must have the patient under observation so as to gain sufficient knowledge of the puerperium.

1. For a clear understanding of this difficulty the wording of the rules of the Central Midwives Board must be kept in mind. One of the certificates which the candidate must put in before admission to the examination is to the effect that she has, under approved supervision, "attended and watched the progress of not fewer than 20 labours, making abdominal and vaginal examinations during the course of labour, and personally delivering the patient" (Rules, Form III.). Such a rule as this, applied as it has been to the exclusion of the Dublin schools of midwifery, is, in my opinion, impracticable and even mischievous. It has been interpreted literally to imply that each individual pupil has attended at least 20 cases, no one of which has been reckoned for the certification of any other pupil. It is not conceivable that this rule could ever have been so framed and interpreted and enforced by a board consisting of medical men or women experienced in the details of the training in obstetrics of students of medicine and midwife pupils, and capable from professional experience of appreciating the reasons for some rule. Such a rule, interpreted literally, is not in force in any school of midwifery in Europe or America. It almost compels evasion or at least interpretation according to the dictates of practical common sense. Everyone engaged in the actual clinical teaching of midwifery must know that two or even three pupils learn more individually from a single case than the solitary student. They sharpen one another's wits by conversation about the case and by comparison of observations, and there is consequently constant exact sustained attention, and no shirking or apathy.

The training of midwives at the Dublin lying-in hospitals is notoriously the best in the United Kingdom. The pupils "reside for a period of six months in the hospital" and receive systematic instruction during the whole term of residence far superior to the requirements of the Central Midwives Board. Probably in the consciousness of this superiority the Master of the Rotunda Hospital replied to interrogatories in a frankly truthful fashion, and the consequence is that, on this narrow technical point in a rule recently formulated, the Dublin hospitals are declared by a majority of the Central Midwives Board to be disqualified from granting to their pupils the certificates necessary to enable them to enter for examination. The unfitness of the Board as at present constituted to exercise judicial functions is well illustrated by the somewhat irrelevant but suggestive remark of one of the members during the discussion of the question to the effect that the Dublin people send out too many midwives, and by the rhetorical question in the course of a formal speech by another member: "Are we going to climb down?"

2. The second point to which I wish to call attention in the difficulty with the Dublin institutions is a very attenuated difference indeed. The Central Midwives Board in drafting its rules thought that ten days was a reasonable time for a pupil midwife to be required to nurse her 20 patients in the puerperium. As all practitioners know there is no special scientific sanction for *ten* days. The period finally fixed was the result of a compromise. Accordingly the candidate before admission to the examination must send in a certificate that she has "nursed 20 lying-in women during the ten days following labour" (Rules, Form IV.). Now this rule was framed in blank ignorance of an important fact with which the Board became acquainted for the first time only on hearing a letter read from the Master of the Rotunda Hospital, writing in his official capacity. He stated *inter alia:* "It would be impossible for our resident nurses to follow the course of the puerperium for ten days, as Irish women will not remain in the hospital for more than eight days." I cannot believe that a single medical member of the Central Midwives Board would have voted in favour of fixing ten days as the minimum period of nursing in the [illegible] been known at the time of framing the [illegible] lying-in hospitals would have been excluded in consequence. But now, "Are we going to climb down?"

The Dublin grievances were discussed after the reading of a letter from the President of the Royal Academy of Medicine in Ireland at a meeting of the Board held on Feb. 25th when eight of the nine members were present. To a mere *non-possumus* motion to the effect that "the rules ...... having been approved by the Privy Council it is impossible for the Board to alter them," one of the usual minority proposed and another seconded an amendment, regretting that the Board was not made aware of the circumstances of the midwifery training schools in Ireland before the rules were sent to the Privy [illegible] and stating "that this Board [illegible] Irish institutions in their difficulties and will give every assistance in order to obtain a revision of the rules by the Privy Council." For this amendment only the proposer and seconder voted; against it five members. For the "*it is* impossible" motion then put substantively there voted six; against it the same two.

Owing to the persistence of the authorities of the Dublin lying-in hospitals the question came up again on April 28th, and although an excellent way out of the difficulty was proposed in a resolution by one of the lay members the result was practically the same. The subject was again under consideration on May 26th on a motion which appeared to indicate a weakening of the opposition but in reality offering no practical [illegible] tions. For an amendment once [illegible] assistance there voted only the [illegible] were opposed. That is how th[illegible] present moment.

Yet the Central Midwives Board is not always so pedantically exact in guiding its conduct by its own rules. In the printed minutes of the meeting of March 24th, which I was unable to attend, I read the following record: "Mrs. H—— stated that she had not undertaken cases without doctors but had been advised by a medical man that she need not be afraid to do [illegible] herself did not feel in any way afraid [illegible] and by no means lucid as the diction [illegible] to have grasped the intention of the [illegible] resolved:—

'That in the opinion of the Board it is desirable that Mrs H—— should be certified, as it appears from her letter that she is quite prepared to take a case alone.'

An [illegible]
the [illegible]

there ever yet who was not "quite prepared", to undertake a case, and preferably "alone"?

This episode appears to [illegible] its remarkable conclusion [illegible] on the agenda paper received by the members. "A letter was read from the deputy clerk" of a county council inclosing an inquiry from this Mrs. H—— and the resolu[illegible]e ado. The [illegible] me the first [illegible]redible violation of the rules. One of the certificates, which such an applicant for admission to the Midwives Roll is required by the rules to supply with her application, is according to Form VIII.: "I hereby claim to be certified under Section 2 of the Midwives Act on the ground that I have been in *bonâ fide* practice as a midwife since ——," one year at least before July 31st, 1902; and the application must be supported by a certificate in Form IX. that she "has, to my personal knowledge, been in *bonâ fide* practice as a midwife since ——," one year at least before July 31st, 1902, "and that she is trustworthy, sober, and of good moral character." But this applicant appears to have produced no evidence whatever except a statement as to her own mental condition, that of self-confidence, and a second-hand opinion from an anonymous medical man. Moreover, she testified to the Board against herself to the effect that she was practising as a monthly nurse and had not been at any time in *bonâ-fide* practice as a midwife. Contrast the levity and inconsistency of the resolution of the Board in this case with its persistently correct and severe attitude towards the Dublin lying-in hospitals. The resolution of the Board to dispense with certificates when the applicant is avowedly a monthly nurse "quite prepared to [illegible] a breach of its own rules; it [illegible]tention of the Act, and but for [illegible]ition of a "midwife" contained [illegible]d have been without question in direct contravention of the statute.

To another grave decision of the Central Midwives Board I desire to call the attention of the medical profession without further delay. At the meeting of the Board held on April 28th a motion was introduced by a lay member to the effect that the Board considers it desirable "to appoint an inspector to visit institutions applying for recognition and to report thereon." The proposer of this motion explained that by the term inspector she meant "a trained woman." It is fair to assume that the intention was to appoint a midwife. A few months [illegible]

[illegible] and consequently no one can be authorised to give the systematic instruction in midwifery who is not a registered member of the medical profession. But by the recent resolution the "trained woman" who is to be appointed and sent to inspect will have, no doubt, to report on the efficiency of the teaching of those qualified men and women who are engaged in giving systematic instruction to midwives in our lying-in hospitals, on the character of the equipment and organisation for systematic and clinical teaching, the sufficiency of the staffs, the sanitary arrangements of the hospitals, including the air space per bed, and other cognate matters. It was strongly objected by one of the minority that such an appointment was not likely to result in efficient inspection and reliable reporting, and that it would be a slight to the medical profession generally and an insult to the individual lecturer to have an inferior order of non-professional person thrust upon him or her as a reporter. It was also pointed out in opposition to the resolution that the county councils and county borough councils have almost universally appointed their medical officers of health as executive officers for the administration of the Midwives Act. [illegible] could be entirely relied upon by the Central Midwives Board as unbiased, accurate, and trustworthy. On the other hand, the irresponsible report of the "trained woman" could no [illegible] relied upon unless it was intended for publication, probably not even then. On a vote being taken with [illegible] members present three voted for the resolution, two of [illegible] being non-medical members, and one voted against it. Three members, two of them medical men, declined to vote. So the resolution was carried. None of the proceedings of the last 18 months more thoroughly demonstrates the defective composition and the consequent bias and sort of moral incompetence of the Central Midwives Board. On an important question of principle like this, involving a kind of degradation of the medical profession and magnifying the midwife's office, three men out of five present, not taken at unawares because the motion had been repeatedly on the agenda paper, refused to vote; and so this serious decision was carried by the votes of one-third of the whole Board, only one of the four medical members present recording his vote against it.

[illegible] in store for us. [illegible] the report of the [illegible] be instituted by [illegible]ion. The meet[illegible] its unanimous [illegible] the Board, consisted of four London members, two of them being medical men. There are still two non-medical members in reserve, so at a full meeting a majority supporting the standing committee will be almost certainly secured. *Inter alia* it recommends under the head of examinations "that one or more women who hold, or have held, the post of matron of a lying-in hospital, or midwife if otherwise qualified, may be appointed examiners." The only reason for this decision that I have heard stated in the Board is that it will be necessary to include "bed-making" among the subjects of examination. So at the beginning of the administration of an Act of Parliament which was brought into existence because of the notorious ignorance and incompetence of English midwives it is seriously proposed to grant to the Midwives Institute the privilege of nominating as examiners its own protégées, women with untrained intellects and equipped with only midwife, *Scoticé* "howdy," knowledge and experience, to set the standard of examinations and to take their places on examining boards on equal terms with qualified practitioners and teachers of midwifery. Surely the examining boards and reporters on examinations ought, in the early stages at least, to be exclusively composed of medical men and women. The professors of bed-making might gracefully postpone the assertion of their claims and wait a while until the system of examinations in mere midwifery has been set on its legs and has had a *fair start*.

The medical profession should keep a critical eye on the recognition by the Central Midwives Board of institutions as training schools and of individuals as teachers of midwife pupils. An abuse of considerable magnitude appears to be in course of creation. To the credit of the Board it may be recorded that there is some hesitation with regard to workhouse infirmaries, but, on the other hand, it seems that hardly anyone of the "ladies' charity" type of institution is too ill-organised, inefficient, or untried and paltry to escape recognition as a school for the training of midwives. As to the professional instructors or lecturers on midwifery I have so far failed to discover any principle guiding the decisions of the Board either in the recognition or the rejection of applicants. As matters are shaping at present there must be at no very distant time a teacher of midwifery in every township. The only satisfaction in contemplating extravagant proceedings is the rather remote prospect opening out behind them, that a reconstituted board must act on diametrically opposite principles and reverse the policy of its predecessors by compelling aspirants for privileges which will secure most of them a professional income for life or good conduct, to seek their professional training within efficiently equipped institutions in the great centres of population and of intellectual activity. There is, however, still some room for the hope that wiser counsels may yet prevail under the enlightened and benevolent criticism of the medical profession, now at last enabled to watch events, and by unofficial advice and assistance minimise the injury to the public interests resulting from the inadequate representation of their profession on the Central Midwives Board.

Manchester.

Physiology.

Inspiration the principal Agent in Venous Circulation.[*]

WE noticed, in a former number,[†] the experiments of Dr. Barry on this interesting subject, and it is principally for the purpose of attending to a practical suggestion afforded by these experiments, that we now return to them. As might be naturally expected, ever since Dr. B. made known his views on the influence of respiration on circulation, it has been attempted to detract from his merits, by asserting that the same thing had been known long before. The great difference, however, between Dr. Barry's views and those of Haller, and others on this point is, that the latter regarded the heart as the primitive cause of the vacuum which operates in the system, whilst Dr. B. attributes the dilatation of the heart itself, and of its proper auricles, to the tendency to form a vacuum which takes place in the whole cavity of the chest during inspiration. In the Report accompanying this memoir there is a subject alluded to of the highest importance, *viz.*, that the act of inspiration which produces the vacuum, and consequently the flow of blood into the cavity of the thorax of those animals which have lungs, is not sufficient to explain the movement of the blood in the veins of reptiles and fishes, which have another mode of respiration, the same coincidence of action not taking place between inspiration and the entrance of venous blood into the heart.

M. Barry is so strongly convinced of the action of the atmosphere on venous absorption, that he regards, as a sure means of preventing the absorption of poison into the system from wounds, the application of a cupping glass on the injured part. From experiments made with reference to this point, the opinion has been verified; nay, more, it has been found that the application of a cupping glass to a poisoned wound, even after a part of the poison has been absorbed, prevents the development of any bad symptoms. Although it appears that the remedy was not unknown to Celsus, still we are indebted to Dr. B. for an explanation of the principle on which its modus operandi depends.

Monstrosities.

M. Geoffroy Saint Hilaire, in a recent meeting of the Academy of Medicine, communicated verbally some very curious details on the various anomalies in the organization which result from the different positions of the egg submitted to incubation: thus, for instance, the vertical position, impeding the development of the chicken, produces a peculiar kind of monstrosity. M. G. St. Hilaire has promised fresh details and experiments, which we trust will throw some important lights on the formation of the different monstrosities.

IRISH MEDICAL SCHOOLS' AND GRADUATES' ASSOCIATION.

A SPECIAL general meeting of this association was held on May 25th at 11, Chandos-street, London, W., to consider the disabilities of the Irish Poor-law medical service.

The chair was taken by Dr. H. MACNAUGHTON-JONES who said that he was qualified to speak on this subject as he had been for several years a Poor-law medical officer both in a large city and in a country district and had nearly lost his life in the discharge of his dispensary duties. The complaints of the dispensary medical officers might be classified as follows: (1) the abuse of dispensary tickets; (2) no allowance for travelling expenses; (3) no definite arrangement for annual vacation; (4) no superannuation or pension for the widows and orphans of those officers who lose their lives in the discharge of their duties; and (5) no arrangement for extra professional service. The Chief Secretary for Ireland had taken a definite stand on the recent report of the Local Government Board for Ireland and in reply to a question asked by Dr. E. C. Thompson in the House of Commons stated that the report contained all the information required. There was evidence that the Local Government Board was aware of the disaffection existing in the medical service but it did not venture to express its sympathy with the medical officers while being in full sympathy with those boards of guardians who might desire to improve the condition of the medical officer. The Board proposed to meet the demands of the officers by reducing their number and uniting the dispensary districts, so in this way increasing the duties and responsibilities of the few remaining officers.

Surgeon-General C. MACD. CUFFE, C.B., A.M.S., stated that he felt strongly on this subject and after reading the recently published report of the commissioner sent to Ireland by the British Medical Association was indignant when he considered the manner in which his brother medical officers in Ireland were treated by the administrators of the Poor-law medical service. This service would never be efficient until it was made a State service and the admission was regulated by competitive examination. At present medical officers served under persons who were entirely out of sympathy with their work. Then as to *private practice in remote districts* he considered it a farce to make such a suggestion, as there was either none to be obtained or so much time was occupied in travelling over the district that the medical officer could not undertake any private practice. He could not understand why medical men adopted the service and considered that it ought to be boycotted by all the medical schools in Ireland and all students should be discouraged from entering it until the present conditions were improved. It was undignified for any medical man to accept £100 a year for his services when the cost of living and education had increased so much. The medical officers had his sympathy.

Dr. J. M. TABUTEAU stated that he had been a medical officer under the Local Government Board for Ireland for nine years and he considered that his circumstances were better than the majority of his brother medical officers. He went to his appointment fresh from his hospital and full of enthusiasm for his work, willing to do his best for the poor people. He soon found his efforts frustrated and that amidst conflicting interests he could neither do justice to his patients nor credit to himself. He did not know of any service which was more likely to sap the strength morally and physically of any young man than the Poor-law medical service of Ireland.

The following motion was then put to the meeting and carried unanimously:—

> That this special meeting of the Irish Medical Schools' and Graduates' Association having before it the recently issued report of the Local Government Board for Ireland on the Irish Poor-law medical service desires to express its opinion that the attitude of the Board as stated in that report does not adequately deal with the reasonable demands of the Poor-law medical officers and offers no permanent settlement of the difficulties now disturbing the relations between the public and the Poor-law medical service.

Mr. P. J. FREYER said that the recent report of the commissioner of the British Medical Association revealed facts which formed pathetic reading and almost moved one to tears. He considered that the position of the Poor-law medical officer was a disgrace to humanity and no one ought to be placed in such a position where it was impossible to perform his duty to his patients who were of the poorest and most destitute class. The amount of salary given was about equivalent to that allotted to the constabulary officer for the keep of one horse and no one could efficiently serve the sick poor in such circumstances. He proposed:—

> That this special meeting of the Irish Medical Schools' and Graduates' Association desires to express its hearty sympathy with the laudable efforts of the Irish Poor-law medical officers to improve the present condition of the Poor-law medical service in Ireland.

Dr. HUGH WOODS seconded the motion and said that the grievances of the medical officers were obvious and the pay was totally inadequate. The remedy, however, seemed to him to be evident and that was combination and coöperation among the medical men themselves.

The motion was carried unanimously.

THE GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

WEDNESDAY, MAY 25TH.

THE seventy-ninth session of the General Medical Council was opened at the Council Chambers, Oxford-street, London, W., on May 25th. Sir WILLIAM TURNER, the President, occupied the chair. After the President had delivered his inaugural address, which was reported in THE LANCET of May 28th, the Council proceeded to the business of the session.

Business Committee.

Sir JOHN BATTY TUKE moved the appointment of the following Business Committee: Dr. MacAlister (chairman), Dr. Windle, Dr. Bruce, and Sir Christopher Nixon. Dr. LITTLE seconded the motion which was agreed to.

Yearly Tables Submitted.

On the motion of Dr. MACALISTER the following yearly tables were received and entered on the minutes:—

[illegible] the medical authorities as to the [illegible] uary, 1904, for commissions in the Indian Medical Service.

Sir PATRICK HERON WATSON moved:—

[illegible] the future continue to be furnishe [illegible]

The motion was seconded by Dr. MCVAIL and agreed to.

Appointment of Assistant Examiner.

On the motion of Sir HUGH BEEVOR, seconded by Mr. MORRIS, it was resolved:—

That Mr. Charles Stonham, F.R.C.S., be appointed as assistant examiner in surgery to the Apothecaries' Society of London for a period of four years, vice Mr. Marmaduke Sheild, who retires by rotation.

The Inspector of Final Examinations.

Dr. MACALISTER moved that the following report from the Executive Committee in regard to the inspection of examinations should be received and entered on the minutes:—

[illegible]

Sir PATRICK HERON WATSON seconded the motion which was agreed to.

In moving the adoption of the report Dr. MACALISTER said that the Council had remitted to the Executive Committee to

[illegible]

were exceptional circumstances in this case which rendered it desirable that the salary should be somewhat greater. On the death of Sir George Duffey only one half-year's stipend was paid to him. Mr. Bryant would have to complete the inspections which were not carried out, and as his year's duty would really include the duty of one half-year more the committee recommended that the salary for the year

[illegible]

In any case he must enter somewhat of a protest against this appointment. If the appointment was only for one year that, of course, mitigated any evil he imagined would exist. He contended that they ought to appoint as inspector of final examinations a man who was in touch with the schools and with the hospitals. It was 15 or 16 years since Mr. Bryant resigned his position at Guy's Hospital and he thought that they could have done better by appointing not a gentleman who was so recently a member of the General Medical Council but a younger man.

Mr. BROWN agreed that if they were to appoint an inspector of final examinations he ought, in justice to the candidates, to be up to date. Mr. Bryant could not be expected to be so efficient an inspector as one who had been in touch with modern methods. He asked whether Mr. Bryant would be required to attend the final examinations of the Apothecaries' Hall of Ireland and said that they ought to have some information as to the examinations which he would attend.

The PRESIDENT said that these were the Scottish Universities and the Universities of London and Oxford. Mr. Bryant's appointment was really to complete the cycle and for that purpose only. He did not wish to re-argue the reasons why Mr. Bryant was selected. He had already given those in his address and nothing that he had heard had led him to alter his opinion.

The report was adopted.

Dental Business.

Dr. MACALISTER moved that the report from the Executive Committee on the dental business transacted since the last meeting of the Council should be received and adopted. The first paragraph stated that the prescribed conditions having been duly fulfilled in each case the names of the following persons had been restored to the Dentists Register from which they had been erased in conformity which the provisions of Section 12 of the Dentists Act, 1878: Reuben Davis, George Neep, Ellis Parsons, William A. Sleigh, and Alice Wilkinson. In paragraph 2 it was explained that the committee had considered an application from Mr. James Dickson Hamilton, a registered dentist of New South Wales, requesting that his name might be placed on the colonial list of the Dentists Register of the United Kingdom and directed that this application should be referred to the General Medical Council and that Mr. Muir Mackenzie should frame an answer for the consideration of the Council. This, said Dr. MacAlister, would be laid before the Council. Paragraph 3 stated that the committee had also considered an application from Mr. Edwin Burton Roper, a dentist of British nationality but domiciled in France, requesting that his name might be placed on the foreign list of the Dentists Register in virtue of his French diploma of Chirurgien Dentiste, which he had obtained after passing three examinations held by the Faculté de Médecine de Paris. This was the first instance of the kind and the merits of the diploma would have to be investigated. The next paragraph chronicled the receipt from the Privy Council Office of a copy of a circular respecting a dental congress at St. Louis, U.S.A., to be held in August next. Paragraph 5 was to the effect that the committee had received from the Colonial Office a copy of an ordinance of the Orange River Colony on the subject of the registration of medical practitioners, dentists, chemists and druggists, midwives, and nurses in that colony which embodied the provisions contained in a proclamation which had been transmitted to the Council in 1902. The Executive Committee, Dr. MacAlister interpolated, expressed its great satisfaction with the provisions which were included in the ordinance, provisions which would be well included in any legislation on the subject that might be undertaken in this country because they absolutely prevented unqualified practice in any of the departments of medicine, dentistry, and so on, and, more than that, they took precautions which seemed to the committee to be sufficient to prevent practice by joint-stock companies. The committee had thought it well to communicate to the Secretary of State for the Colonies its satisfaction at the character of the ordinance. The only remaining points in the report were that the committee had received from the Colonial Office a copy of an Act to consolidate and to amend the law relating to dentists in Tasmania and from the Irish branch of the British Dental Association a communication calling attention to a judgment in regard to medical or dental joint-stock companies.

Dr. LINDSAY STEVEN seconded the motion which was agreed to.

Mr. BROWN asked whether it was intended to take any official action in regard to the last point in the report—the communication from the Irish branch of the British Dental Association.

Dr. MACALISTER said that the Executive Committee

M. G. St. Hilaire has promised fresh details and experiments, which we trust will throw some important lights on the formation of the different monstrosities.

IRISH MEDICAL SCHOOLS' AND GRADUATES' ASSOCIATION.

A SPECIAL general meeting of this association was held on May 25th at 11, Chandos-street, London, W., to consider the disabilities of the Irish Poor-law medical service.

The chair was taken by Dr. H. MACNAUGHTON-JONES who said that he was qualified to speak on this subject as he had been for several years a Poor-law medical officer both in a large city and in a country district and had nearly lost his life in the discharge of his dispensary duties. The complaints of the dispensary medical officers might be classified as follows: (1) the abuse of dispensary tickets; (2) no allowance for travelling expenses; (3) no definite arrangement for annual vacation; (4) no superannuation or pension for the widows and orphans of those officers who lose their lives in the discharge of their duties; and (5) no arrangement for extra professional service. The Chief Secretary for Ireland had taken a definite stand on the recent report of the Local Government Board for Ireland and in reply to a question asked by Dr. E. C. Thompson in the House of Commons stated that the report contained all the information required. There was evidence that the Local Government Board was aware of the disaffection existing in the medical service but it did not venture to express its sympathy with the medical officers while being in full sympathy with those boards of guardians who might desire to improve the condition of the medical officer. The Board proposed to meet the demands of the officers by reducing their number and uniting the dispensary districts, so in this way increasing the duties and responsibilities of the few remaining officers.

Surgeon-General C. MACD. CUFFE, C.B., A.M.S., stated that he felt strongly on this subject and after reading the recently published report of the commissioner sent to Ireland by the British Medical Association was indignant when he considered the manner in which his brother medical officers in Ireland were treated by the administrators of the Poor-law medical service. This service would never be efficient until it was made a State service and the admission was regulated by competitive examination. At present medical officers served under persons who were entirely out of sympathy with their work. Then as to private practice in remote districts he considered it a farce to make such a suggestion, as there was either none to be obtained or so much time was occupied in travelling over the district that the medical officer could not undertake any private practice. He could not understand why medical men adopted the service and considered that it ought to be boycotted by all the medical schools in Ireland and all students should be discouraged from entering it until the present conditions were improved. It was undignified for any medical man to accept £100 a year for his services when the cost of living and education had increased so much. The medical officers had his sympathy.

Dr. J. M. TABUTEAU stated that he had been a medical officer under the Local Government Board for Ireland for nine years and he considered that his circumstances were better than the majority of his brother medical officers. He went to his appointment fresh from his hospital and full of enthusiasm for his work, willing to do his best for the poor people. He soon found his efforts frustrated and that amidst conflicting interests he could neither do justice to his patients nor credit to himself. He did not know of any service which was more likely to sap the strength morally and physically of any young man than the Poor-law medical service of Ireland.

The following motion was then put to the meeting and carried unanimously:—

> [illegible] of the Irish Medical Schools' and [illegible] g before it the recently issued report of [illegible] or Ireland on the Irish Poor-law medical service desires to express its opinion that the attitude of the Board as stated in that report does not adequately deal with the reasonable demands of the Poor-law medical officers and offers no permanent settlement of the difficulties now disturbing the relations between the public and the Poor-law medical service.

Mr. P. J. FREYER said that the recent report of the commissioner of the British Medical Association revealed facts which formed pathetic reading and almost moved one to tears. He considered that the position of the Poor-law medical officer was a disgrace to humanity and no one ought to be placed in such a position where it was impossible to perform his duty to his patients who were of the poorest and most destitute class. The amount of salary given was about equivalent to that allotted to the constabulary officer for the keep of one horse and no one could efficiently serve the sick poor in such circumstances. He proposed:—

> That this special meeting of the Irish Medical Schools' and Graduates' Association desires to express its hearty sympathy with the laudable efforts of the Irish Poor-law medical officers to improve the present condition of the Poor-law medical service in Ireland.

Dr. HUGH WOODS seconded the motion and said that the grievances of the medical officers were obvious and the pay was totally inadequate. The remedy, however, seemed to him to be evident and that was combination and coöperation among the medical men themselves.

The motion was carried unanimously.

[*] Recherches Experimentales sur les Causes de Mouvement du Sang dans les Veines, par David Barry, M.D., avec le Rapport de M. le Baron Cuvier et de M. le Professeur Dumeril. Paris, 1825.

[†] Vide LANCET, Vol. X., No. 5, p. 140.

The third and last piece of penal business was the consideration, adjourned from Nov. 26th, 1903, of the case of Robert Fawcitt Granger, registered as of 85, Church-street, Whitby, with the triple qualificat [illegible] had been summoned to appear [illegible] sequence of his conviction in Ply [illegible] children.

The PRESIDENT, addressing Mr. Granger, said he would recollect that in November he was asked to appear before the Council in May to give some evidence of what he had been doing between these two dates. There had been put into his (the President's) hands a certificate by Dr. Robert Milne, Sturg House, 32, Bow-road, E., and a statement by Mr. Granger himself, from which he gathered that he had been in practice in the Mile End-road since the beginning of the year. He also gathered from this statement that he had had many difficulties to overcome in connexion with the obtaining of a practice, but at the end of the statement it was mentioned that three weeks ago he was appointed medical officer in a dispensary and that his prospects were better now than at any time during the last two years. He would just ask him this question, Had he been what he promised he would be—namely, an abstainer?

Mr. GRANGER: Practically.

The case was then considered *in camerâ*, after which

The PRESIDENT said: The Council has now given further consideration to your case and we have had before us Dr. Milne's letter, a letter from the inspector of the National Society for the Prevention of Cruelty to Children, and also your own letter, and the Council has come to the resolution not to proceed any further with the case, so that you can leave the council chamber feeling that this matter is done with. All I would like to say is that I hope you will have profited by this experience and that your conduct in the future will be all that we should desire it to be.

Mr. GRANGER then left.

The Registration of a Colonial Dentist.

Dr. MACALISTER submitted the next business, which was an application from Mr. James Dickson Hamilton for registration as a dentist in the United Kingdom. On Oct. 5th, 1903, the application was received from Messrs. Sparke and Angus, a firm of solicitors in Sydney, on behalf of Mr Hamilton that he might be registered as a colonial dentist in the Dentists Register under Section 8 of the Dentists Act, 1878, the grounds of the application being that he was already registered under the Dentists Act of New South Wales and [illegible] had been th [illegible] spondence [illegible] Committee [illegible] Messrs. Sparke and Angus for the consideration of the Council. The following was the proposed answer prepared by Mr. Muir Mackenzie:—

> [illegible] er of Nov. 23rd, 1903, I have to [illegible], James Dickson Hamilton and [illegible] and your letter have been con- [illegible]
>
> [illegible] 274).
>
> With [illegible] registere [illegible] determir [illegible] (Victoria [illegible] ised, but the [illegible] ces stated in [illegible] e registration [illegible] tions will be [illegible] 216, 242, 162, [illegible] has therefore been refused by the Council on the grounds above stated.

Sir VICTOR HORSLEY moved that the Council adopt this answer. Those, he said, who had followed the case of Oldfield in times past would be much obliged to Mr. Muir [illegible] for producing such an extremely clear and convincing statement of the attitude of the Council on this, at first sight, rather complicated matter.

Dr. MACALISTER seconded and the motion was agreed to.

Appointment of Committees.

The nominations for the following committees were adopted:—

Examination Committee.—By the English Branch Council: Dr. Pye-Smith, Dr. Payne, and Mr. Young. By the Scottish Branch Council: Sir Patrick Heron Watson, Dr. Finlay, and Dr. McVail. By the Irish Branch Council: Sir Charles Ball, Dr. Little, and Sir W. Thomson.

Education Committee.—By the English Branch Council: Dr. Norman Moore, Dr. MacAlister, and Dr. Windle. By the Scottish Branch Council: Sir John Tuke, Dr. McCall Anderson, and Dr. Mackay. By the Irish Branch Council: Dr. Bennett, Sir C. Nixon, and Sir W. Thomson.

Public Health Committee.—By the English Branch Council: Sir G. Philipson, Mr. Power, and Mr. Jackson. By the Scottish Branch Council: Dr. Lindsay Steven, Dr. McVail, and Dr. Bruce. By the Irish Branch Council: Sir Charles Ball, Mr. Tichborne, and Dr. Bennett.

It was also agreed that the following should be the members of the Dental Committee: the President (chairman), Sir Charles Ball, Sir Patrick Heron Watson, Mr. Tomes, and Mr. Henry Morris; that the following should be the members of the Dental Education and Examination Committee: Mr. Tomes, Mr. Brown, Dr. Lindsay Steven, Dr. Finlay, Sir Charles Ball, Dr. Bennett, and Mr. Henry Morris; that the following should be the members of the Pharmacopœia Committee: Dr. MacAlister, Dr. Norman Moore, Dr. Payne, Sir George Philipson, Sir John Batty Tuke, Dr. McVail, Sir John Moore, and Mr. Tichborne; and that the following should be the members of the Students' Registration Committee: Sir Hugh Beevor, Dr. MacAlister, Sir John Batty Tuke, Dr. Mackay, Dr. Bennett, and Sir William Thomson.

The Council then adjourned till Friday.

FRIDAY, MAY 27TH.

The session was resumed on Friday, Sir WILLIAM TURNER being in the chair.

Preliminary Scientific Education and Examination.

Dr. NORMAN MOORE moved that the report from the Committee on Preliminary Scientific Education and Examination be received and entered upon the minutes. He said the Council would remember that a joint committee of the Education and Examination Committees was appointed to go into the whole question of preliminary scientific education and examination. Everyone who had read this report would find that it contained a most valuable collection of information on the subject. With the aid of the President the committee obtained information from a very large number of licensing bodies and medical and scientific institutions. He might add that the reason why the number of medical and scientific institutions was not increased by other medical schools in London was that these schools considering they were part of the University of London intimated that they would reply through the university. The university was unable to ask each school to express its opinion. That would have been an enormous labour, so that only one or two of the London medical schools had actually replied to the Council. The others would have been perfectly willing to do so if the university had seen fit to consult them on the matter. The answers, which had been very carefully summarised, were singularly of one complexion. There was no very great difference of opinion among any of those bodies. The committee having thoroughly discussed and digested the reports had drawn up eight recommendations which it suggested should be communicated to all the licensing bodies. He ought to say that these resolutions practically embodied what the licensing bodies and the teaching institutions approved of. They were not absolutely unanimous but the general agreement was obvious.

Dr. WINDLE seconded the motion which was agreed to.

Dr. NORMAN MOORE then moved that the first recommendation be adopted, viz:—

> That an examination in chemistry in order to be sufficient should comprise a written paper, a practical examination, and an oral examination.

Dr. WINDLE seconded the motion which was agreed to without discussion.

Dr. NORMAN MOORE moved the second recommendation which was as follows:—

> That in respect of chemistry a synopsis of subjects should be issued by each licensing body and that the scope of the examination in chemistry should not fall below that which has been indicated in the report of the visitors and has been generally approved by the licensing bodies.

Dr. WINDLE seconded the motion.

Dr. MACALISTER said the publication of the synopsis of subjects was useful not only to the schools as a guide and the examiners as a control but to other bodies in estimating the scope of the examinations held by any particular bodies. This was one of the strongest reasons given for the publication of the synopsis in all cases. Another reason was to emphasise the very general approval which was given by various experts in different licensing and teaching bodies to the outlined scope of an examination in chemistry which was submitted by Dr. Campbell Brown and he could not help thinking that it emphasised their appreciation of the report which he and Dr. Windle previously presented to the Council.

Sir JOHN MOORE suggested that the words "or syllabus" be inserted after "synopsis." That was a recommendation of the Irish Royal Colleges and he thought there was something in it. The syllabus gave a little more information to the students than the synopsis did.

It was agreed to insert the words "or syllabus" and the recommendation so amended was adopted.

Dr. NORMAN MOORE moved the adoption of the third recommendation which was:—

> That the examination in practical chemistry should not be limited to simple qualitative analysis but should include easy preparations and simple experiments illustrating important principles.

Dr. WINDLE seconded the motion.

Mr. TICHBORNE considered that the question of volumetric analysis should be specifically introduced.

Sir VICTOR HORSLEY remarked that this matter arose more in connexion with the course of study than examinations. The motion only related to examinations.

Dr. PYE-SMITH, while acknowledging the value of volumetric analysis, said that for the Council to impose it as a necessity for every medical student seemed to be pushing things too hard. Whatever they did he ventured to predict that the chemist would give papers which would not be either simple or easy. If he had his way he would print these two adjectives in italics. The university examination should insist on chemistry carried as high as it was reasonable to do. It was most important that every man who was a doctor of medicine in this kingdom should be a good physiologist and a good chemist, but they were not legislating for a university degree and they would not do any good by making the student's access too difficult.

Mr. TICHBORNE said that in regard to volumetric analysis they would be examining a man practically. It was a mode of manipulation which must have extensive use. He therefore moved as an amendment to insert after the word "preparations" the words "rudiments of volumetric analysis."

Dr. BRUCE seconded the amendment.

Dr. PAYNE said the syllabus would be somewhat defective if volumetric analysis were not introduced. Volumetric analysis was a method, not a thing learned by heart, and it was very necessary, if not absolutely necessary, in the daily practice of medicine.

On the suggestion of Sir JOHN MOORE Mr. TICHBORNE agreed to alter his amendment so as to read "simple volumetric analysis."

It was agreed to insert these words in the committee's recommendation which was then adopted in its amended form.

The fourth recommendation—viz.,

> That an examination in physics in order to be sufficient should comprise a written paper and an oral examination, the latter to include practical questions on the use of physical instruments and apparatus—

was agreed to without discussion on the motion of Dr. NORMAN MOORE, seconded by Dr. WINDLE.

The fifth recommendation was similarly adopted, viz.:—

> That in respect of physics a synopsis or syllabus of subjects should be issued by each licensing body and should include the elementary mechanics of solids and fluids and the rudiments of heat, light, and electricity.

Dr. NORMAN MOORE stated that this recommendation was a re-affirmation of the resolution of the Council, now of many years' standing.

Dr. NORMAN MOORE, in moving the adoption of the sixth recommendation, which was—

> That elementary biology should be retained in the curriculum,

said there was greatest room for discussion on this clause. After receiving the various reports he thought he was justified in saying that the conclusion the committee came to was that its recommendation represented the feeling throughout the world of medical education.

Dr. WINDLE seconded the motion.

Dr. MACKAY said most of them knew what tremendous difficulties medical students were at once plunged into by the faults of the curriculum. The medical subjects had increased greatly of recent years. The subjects of bacteriology had increased, public health had become of tremendous importance and would go on increasing in importance. The examiners were paying more attention to details of medical studies such as mental diseases and ophthalmology and when it was sought to relieve the curriculum they were forced to turn to the subjects of the first professional examination. He should be loath to propose anything which should diminish the care given to physics and chemistry but in regard to biology he held a different opinion. He was well aware that the great majority of the teaching institutions had replied to the Council that the subject of biology ought to be retained in the curriculum and he believed with them that biology had a very considerable educational value. But at the same time he thought that in view of the overburdened state of the curriculum biology should only be retained in a way that would interfere as little as possible with the other professional subjects. It was absolutely impossible for any student properly to study four great sciences within the first year of his curriculum. His proposal therefore was that while retaining biology in the curriculum they should exclude it from the examination subjects. Of course, this method of treating the subject opened up the possibility of putting other subjects on a similar footing. The proposal he now desired to submit was in the form of the following amendment:—

> That the Council is of opinion that while the subject of biology should be retained in the curriculum it will not regard it as necessary that a professional examination in the subject should be demanded, provided the student has attended and duly performed the work of a satisfactory course of instruction in the subject as part of his curriculum at a university or duly recognised school of medicine.

Sir JOHN BATTY TUKE said that he seconded the amendment with very great pleasure, more especially as it brought before the notice of the Council the principle of instruction without examination in order to reduce the amount of weary grind that went on and resulted in no intellectual activity and the acquisition of the minimum of knowledge.

After some discussion on procedure it was agreed to go into committee, so that paragraphs 6, 7, and 8 might be taken in conjunction and more freely debated. The three paragraphs were as follows:

> That elementary biology should be retained in the curriculum.
>
> That an examination in elementary biology in order to be sufficient should comprise a written paper and an oral examination, the latter to include practical questions on specimens and dissections and on methods of microscopical investigation.
>
> That, in respect of elementary biology, a synopsis of subjects should be issued by each licensing body.

Meanwhile, Dr. MACKAY withdrew his amendment. The Council having resolved itself into committee, Sir VICTOR HORSLEY proposed as a motion:

> That the further consideration of recommendations 6, 7, and 8 of the report of the Committee on Preliminary Scientific Education be suspended and that the committee be reappointed and instructed to report upon the courses of study and synopses of subjects for the preliminary scientific examination with especial reference to the branches of biology as subjects of study and examination.

He said that everything turned on what was meant by biology, and naturally they looked into the report of the committee to find what the committee meant by the term. For the first time he was a hostile critic of that body. The reference to the committee was far wider than it appeared to have accepted; it included the whole question of preliminary scientific education and examination, but the committee had not fully reported upon the courses of study and the synopses of subjects. Personally he felt that the Council owed it as a duty to the licensing bodies to indicate what it considered should be the courses of study and the subjects for these scientific examinations and until the Council had done that he thought it had not done its duty towards the medical student. The only way to fulfil this duty was obviously to reappoint the committee and to ask it to report upon the subject, say, next session. There was no hurry. Another consideration in support of the reappointment of the committee was that in England there were a great difference of opinion and considerable feeling in the minds of some members of the profession as to the relative value of biology. They must have advice and instruction from the committee and he thought that his amendment covered Dr. Mackay's point.

Sir **CHARLES BALL** seconded the motion.

Dr. **MACALISTER** said that if the proposal meant that the committee or the Council afterwards was to draw up anything like an ideal synopsis of the contents of elementary biology then he thought that the Council was embarking on a task for which it was not fitted. It was quite impossible for the Council without taking expert advice to frame anything like an ideal, uniform, and universal syllabus on the subject. What the committee did was to go to those who had experience in the teaching and examination of this subject for many years. It sent an extremely fair letter to all the teaching and examining bodies concerned with this subject in the United Kingdom and the result was very striking. Every single licensing body in the country except the Apothecaries' Hall of Ireland and the Royal College of Surgeons in Ireland thought that biology ought to be retained in the curriculum as a necessary subject of preliminary medical examination. Was it, after all, practicable for the Council to lay down that a subject should be a subject of teaching and not a subject of examination? If a subject was explicitly excluded from examination by the Council it would very soon be excluded from study. The real question was: Did the teaching of biology do any good? He thought it did; the teaching of the subject in the first year saved the student's time afterwards.

Sir **WILLIAM THOMSON** said that the speech just made showed that the further consideration of the subject ought to be postponed. Dr. MacAlister had shown what were the arguments in favour of the retention of the subject, and, on the other hand, they had heard from Dr. Mackay a speech which for the moment he thought carried considerable conviction to the Council. Dr. Mackay had proposed a procedure which was very novel and perhaps very attractive to the student but he did not know whether it would be attractive to those who had to do with medical education at large. Year by year they had been piling up the work of the medical student and it was becoming more and more evident that five years were quite insufficient to enable him to master the details of his course, if, indeed, he was making any attempt at the result. Dr. Mackay's suggestion was a most important one. It was entirely new and once they adopted it they must apply it to other subjects. He should like the committee to suggest some means by which, if biology was only to be an instructional course, it should be a *bonâ fide* course and not a farce. It would not do for the Council to associate itself with any arrangement which could be evaded by any corporation or teaching body.

Sir **CHARLES BALL** expressed the opinion that the matter was not in any way ripe for decision that day. There should be delay.

t seemed to him an
of opinion that had
glish Royal Colleges
in connexion with the preliminary subjects of medical education, and especially in connexion with biology, that they should now have a proposal that biology should merely be made a subject of instruction and not of examination. It was quite clear that if the proposal were agreed to biology would be excluded *from instruction as well as from* examination.

Dr. **PYE-SMITH** remarked that it had been said that biology was a vital question in the student's curriculum and he thought it would be a great pity if the Council did not stand up to what it had already done in this respect. He was sure that the result put before the Council by the committee whose report they were now discussing was very valuable indeed. He would urge the Council not to let the present opportunity pass. He was of opinion that this important subject was ripe for decision. None of the members of the Council spoke of it without at least some knowledge of the subject and in these circumstances he deprecated referring the matter to experts. He believed that biology was a valuable subject for preliminary medical study. He did not see how they could in the face of the reports which they had strike out such an important subject. They must not try to turn the students into automatons. Biology was a subject which could not well be taught in schools. That
favour of retaining it. But,
was the all but unanimous
He did not think that the Council ought to go beyond that. However, he considered that the Council should not try to fetter with a minute syllabus the teaching or the examining of this subject. He thought it would be as disastrous to make a minute supervision of the subjects to be examined in as to make everyone go through the same mould.

Dr. **WINDLE** agreed with Dr. Pye-Smith that it would be inadvisable for the Council to draw up a syllabus of biology. There was a divergence of opinion respecting the best way in which biology should be taught. Biology was essentially a growing subject in which a great deal of elasticity should be allowed to teachers and in which experiments should be made. For these reasons it would be injudicious to try to draw up a syllabus on the subject. Dr. Mackay's point was one of the most important which had been before the Council. He thought that in the principle of instruction without examination the Council would find the solution to many of their difficulties. The crux of the situation was that the institutions which were the teaching were not always the examining bodies. The solution to his mind was that the bodies which carried out the examinations should satisfy themselves that the instruction in the schools was of a sufficient and proper character. He was highly sceptical as to the teaching of biology saving time for anatomy. He did not think that it had saved those of them who were anatomists much trouble. It was of help to the student when he came to pathology. The teaching of biology was very important in the part it took in building up the medical character.

Dr. **MACALISTER** moved as an amendment—

> That it was desirable that elementary biology should be retained in the curriculum.

Sir **VICTOR HORSLEY** said that he was personally in favour of retaining biology but he did not think that the amendment was in order.

Dr. **MACALISTER** said that when they discussed the recommendations someone must make a specific motion.

Dr. **MCVAIL** thought that Sir Victor Horsley was right in thinking that Dr. MacAlister's amendment was not a proper one. Continuing, he said that nothing had emerged to show him that the committee could bring in any more satisfactory report six months hence on the subject of teaching in biology than it had done. It was not possible at the present time with the existing development of the subjects included in biology for any committee to draw up a syllabus in it which would be a working syllabus for all the bodies in the *United Kingdom*. It would, he thought, be quite impossible to draw up a syllabus which would suit the University of London and the University of Cambridge, and also the Apothecaries' Society. Nor did he consider it possible for any committee of the Council to say that there was a minimum syllabus of biology. When biology was brought in first it was very carefully considered, but nobody then could lay down more than "elementary biology." They had received a syllabus from each of the bodies throughout the country with one exception respecting the teaching of biology. There was not one syllabus which was not sufficient, but they differed not only as to standard but as to the subjects which were taken up. Some gave more attention to one department, some to another. He did not think, therefore, that any committee would be able to lay down any such minimum syllabus of biology as the Council would be justified in making a requirement and in demanding that the licensing bodies should adhere to. Nevertheless he strongly went in for the retention of biology. No case had been made out for giving it up. What a tyranny there would be in the school in which at the end of the session it should lie with the teacher to say that a man was to go on or not. Anything more retrograde than the proposal of Dr. Mackay he had not heard for a very long time and he hoped that the vote would go against Sir Victor Horsley's motion.

Dr. MacAlister's amendment was allowed to drop.

Dr. **NORMAN MOORE** observed that it would be wasting the time of the Council if they were to go further into a subject which the committee had considered at great length. It had also been discussed in a very large number of teaching institutions whether biology should be retained in the curriculum. The general consensus on the part of teachers had been that it was desirable to retain biology as a part of medical education. They could not get beyond that. He therefore moved, as an amendment to Sir Victor Horsley's motion:

> That instead of postponing the consideration of the report of the committee, Clauses 6, 7, and 8 be approved of by the Council in committee.

Mr. MORRIS seconded the amendment. He said that he did not think further postponement of the subject would bring forth further information. The very large number of replies received in answer to the questions sent out, the great unanimity of those answers, and the very admirable, concise, and clear report itself did not lead him to anticipate that they would get anything else in the form of information which the committee had not before it at the present time. It was sought to introduce a very important new principle into the curriculum—namely, that subjects should be taught but that the students should not be examined in them. He did not think that the time had arrived for that. He did not think it reasonable that any subject should be introduced into the curriculum for study and not be followed by examination. It would be of the nature of a dead letter.

Sir VICTOR HORSLEY submitted that the amendment was not a competent one. He had already pointed out that the committee had only dealt with the subject of examination and not with the course of study. He put forward a course of study and he did not think the amendment was quite in order to his motion.

Dr. MCVAIL considered that Dr. Moore's amendment should be put as it stood. If carried it would become a substantive motion.

The PRESIDENT said that he should put the motion as a whole and the amendment as a whole.

Dr. Norman Moore's amendment was carried by 19 votes to 10.

Upon its being put as a substantive motion,

Dr. MACKAY said that he should still like to take the view of the committee on his own proposal pure and simple.

Dr. MACALISTER, on a point of order, said that Dr Mackay's proposal did not concern clauses 6, 7, or 8 in any essential sense but was a general question.

The PRESIDENT pointed out that the proper stage for Dr. Mackay's motion would be after the Council resumed.

Sir VICTOR HORSLEY said that on the motion now before them he agreed that elementary biology should be retained in the curriculum, but if he were to agree to the motion as it stood he must know what he was voting for He must know what was meant by elementary biology. He was quite ready to vote for clauses 6, 7, and 8 on the ground of pure examinational requirements but he must have some sort of idea of the subjects and courses of study for the examination. He wished to know whether if he voted for clauses 6, 7, and 8 he would be precluded from bringing forward the question of courses of study.

The PRESIDENT said that No. 6 was a general proposition to the effect that elementary biology should be retained in the curriculum. There was nothing in clauses 6, 7, or 8 to define what the course of elementary biology should be. The feeling of the committee was that they should not define elementary biology in any minute sense, but that it should be left to the educational bodies and the licensing bodies themselves to stipulate what the course of study was to be which they would require for examination.

Sir VICTOR HORSLEY said the recommendations of the committee only related to examinations. He therefore wanted to come back to the question of study and take the opinion of the Council by a clear vote on this matter. He asked whether he would be able to do so after passing clauses 6, 7, and 8

Dr. MCVAIL said that Sir Victor Horsley wanted the committee to consider what should be in a synopsis. No. 6 was quite general, being simply to retain elementary biology. It did not refer to examination or curriculum. No. 7 was that there should be an examination. No. 8 did not refer specifically to examination at all. It said that in respect of elementary biology a synopsis of subjects should be issued by each licensing body. That synopsis might be for examination or curriculum, or it might be for both. Sir Victor Horsley from his own point of view should move an amendment to Dr. Norman Moore's motion that Nos. 6 and 7 be approved, and when that was carried he could raise the question of referring No. 8 to the committee.

Sir VICTOR HORSLEY said he thought that it would be more convenient if he raised his motion at the end of these recommendations. As to No. 7, on its merits he thought the subject should be in the curriculum, but he agreed that the time had now come when they should consider whether it was necessarily an examinational subject. He did not agree with the statement that their curriculum only included subjects necessarily examined in, because it contained subjects which could not be examined in, in the true sense of the word, and some minor subjects which were not examined in at all. No. 7 as it stood was a very important resolution of the Council, because if they looked at it they would see that it put biology on exactly the same footing as chemistry and physics. Personally he did not feel that biology should be on the same footing as chemistry and, he would add, physics. If there was to be a reconsideration of the degree and status of examination and if they were only carrying a vague kind of principle just now he would vote for it.

Dr. Norman Moore's amendment as a substantive motion was then agreed to and the Council resumed. What had been done in committee was formally approved of.

Dr. NORMAN MOORE moved

> That resolutions 1 to 8 adopted by the Council be communicated to all the licensing bodies.

Mr. MORRIS seconded the motion which was agreed to.

Dr. MACKAY said he thought that the matter which he had raised should be carefully considered. There were many who thought that the time was ripe for the change; if it was found that the time was not ripe no harm would have been done by the consideration. He would therefore propose:

> That the Preliminary Scientific Committee be re appointed and that the following suggestion submitted to the Council be referred to them for report—namely, that the subject of biology should be retained in the curriculum but that it should not be regarded as necessary that a professional examination in the subject should be demanded provided the student has attended and duly prepared and performed the work of a satisfactory course of instruction in the subject as part of the curriculum at a university or duly recognised college or school of medicine.

Sir JOHN BATTY TUKE seconded the motion.

Dr. FINLAY expressed the opinion that it would be a mistake to make the reference too narrow. The committee ought to be able to take up the question of non-examination in many of the subjects.

Dr. LINDSAY STEVEN also took the view that the inquiry should be general and not particular.

After further discussion

Dr. FINLAY moved as an amendment to Dr. Mackay's motion

> That the committee be re-appointed and instructed to consider and report as to the advisability of dispensing with examinations in the case of any of the subjects in which courses of study are prescribed by the licensing bodies.

Mr. MORRIS seconded this amendment

Dr. MCVAIL said that the Council had just decided to send out an opinion as to the examination in biology and here they were now proposing to send out an entirely different, in fact, contradictory, opinion. If it were desired to make the Council ridiculous he could not imagine a better way of doing it. The thing was absurd; it was utterly unworthy of the Council and of the great universities and corporations that the Council was supposed to assist and to direct.

Mr. MORRIS said that although he had seconded Dr. Finlay's amendment he had done so merely to escape from the position that would be created by the passing of Dr. Mackay's motion and so little was he in favour of Dr. Finlay's amendment which he had seconded that he would be happy to vote against it when it came to be put as a substantive motion.

Sir VICTOR HORSLEY said that surely the speech they had just listened to was the way to make the Council absurd. He considered that Dr. McVail's observations were entirely unwarranted by the facts. Personally, he preferred Dr. Finlay's amendment as being the wider statement of the same proposition.

Dr. BRUCE said he thought that the Council was not in a condition to decide the question that day. Due notice of the proposals should be given.

Dr. BENNETT then moved the previous question and Dr. MCVAIL seconded the motion.

On a vote 13 members supported the motion and 14 voted against it. The previous question was accordingly lost.

Dr. MACKAY suggested that they should put the matter on the next day's programme of business for discussion.

The PRESIDENT: You ask that for your own motion?

[illegible] Dr. Finlay): Are you agreeable [illegible]

Dr. FINLAY: No; I am not. Continuing, Dr. Finlay said [illegible] ement would be a waste of the [illegible]

[illegible] put Dr. Finlay's amendment to [illegible] 16 votes to 12. Two members did not vote and two were absent. Names and numbers were taken as follows:—For (16): Dr. MacAlister, Dr. Norman Moore, Mr. Morris, Sir Charles Ball, Dr. Mackay, Dr. Caton, Mr. Jackson, Sir Christopher Nixon, Sir Victor Horsley, Dr. Windle, Dr. Finlay, Sir William Thomson, Dr. Bruce, Dr. Little, Sir Hugh Beevor, and Sir John Batty Tuke. Against (12): Dr. Payne, Dr. Pye Smith, Sir John Moore, Mr. Young, Dr. McVail, Sir Patrick Heron Watson, Dr. Lindsay Steven, Mr. Brown, Mr. Tichborne, Sir John Williams, Dr. Bennett, and Sir George Philipson. Did not vote (2): The President and Dr. McCall Anderson. Absent (2): Mr. Power and Mr. Tomes.

Dr. FINLAY'S amendment was then put as a substantive motion. 13 members voted for it and 15 against it and it was declared lost. Two members did not vote and two were absent. Names and numbers were again taken as follows:—Against (15): Dr. MacAlister, Dr. Norman Moore, Mr. Morris, Dr. Payne, Dr. Pye Smith, Sir John Moore, Mr. Young, Dr. McVail, Sir Patrick Heron Watson, Dr. Lindsay Steven, Mr. Brown, Mr. Tichborne, Sir John Williams, Dr. Bennett, and Sir George Philipson. For (13): Sir Charles Ball, Dr. Mackay, Dr. Caton, Mr. Jackson, Sir Christopher Nixon, Sir Victor Horsley, Dr. Windle, Dr. Finlay, Sir William Thomson, Dr. Bruce, Dr. Little, Sir Hugh Beevor, and Sir John Batty Tuke. Did not vote (2): The President and Dr. McCall Anderson. Absent (2): Mr. Power and Mr. Tomes.

The PRESIDENT: Dr. Mackay, your original motion is also gone.

Notices of Motion.

The following notices of motion were given:—

By Sir VICTOR HORSLEY:

That the Preliminary Scientific Committee be reappointed and instructed to consider and report upon courses of study in chemistry, physics, and elementary biology.

By Dr. MACKAY:

That the Education Committee be requested to collect information and report on the subject of the possibility of including certain subjects in the curriculum without requiring examination in them.

By Dr. LINDSAY STEVEN:

[illegible] ituted by himself and involving the [illegible] of the entry money and the subscrip [illegible] s looked upon by this Council as con [illegible] ing to have been guilty of infamous conduct in any professional respect.

The Council then adjourned till Saturday.

SATURDAY, MAY 28TH.

The Council resumed business on Saturday, Sir WILLIAM TURNER presiding.

The Curriculum and Examination in Scientific Subjects

Dr. NORMAN MOORE moved that the communications referred to the General Medical Council by the Executive Committee from the Royal College of Physicians of London [illegible] England in regard to [illegible] itific subjects should [illegible] ch was agreed to.

The following are the terms of the communications:—

(a) [illegible]

DEA[illegible]

[illegible] nich have now been adopted by this [illegible] e of Surgeons of England [illegible] es will be incorporated in the regula [illegible] take effect from March, 1905.

I am, dear Sir, faithfully yours,
EDWD LIVING, M D, Registrar.

H. E. Allen, Esq, Registrar, General Medical Council.

COURSES OF INSTRUCTION.

1. That a minimum length of courses be required in chemistry, physics, and biology before candidates are admitted to examination in these subjects.

2. That the minimum course in the several subjects be:

In chemistry 180 hours' instruction and laboratory work.
In physics 120 " " "
In biology 120 " " "

3. That these courses need not run concurrently, nor be completed within one year.

[illegible]

6. That the study of anatomy and physiology be not recognised until after the first examination in chemistry, physics, and biology has been passed.

7. That no student be admitted to examination in medicine and [illegible] udy after [illegible], towards [illegible] ounted, if [illegible]

FIRST PROFESSIONAL EXAMINATION.

That Part I. Chemistry, Part II. Physics, Part III. Biology, and, at the option of the candidate, Part IV Practical Pharmacy, be the subjects of the first examination.

Chemistry.

1 That the paper in chemistry do consist of nine questions, six to be answered and no more, for which three hours shall be allotted.

2 That the time for the practical examination be extended from two to three hours

3. That the use of books and tables be allowed in the practical examination.

Physics.

4 That there be a separate paper in physics consisting of six questions, four to be answered and no more, for which two hours shall be allotted

5 That there be a *vivâ voce* examination on the use of physical [illegible] chemistry and physics [illegible] rded in chemistry and [illegible] lates who obtain 40 per [illegible] ss provided that they [illegible]

Biology

7. That in addition to the *vivâ voce* examination there be a paper in biology for which two hours shall be allotted, consisting of six questions, four to be answered and no more.

8. That each candidate be examined orally for 15 minutes.

Then follow synopses [illegible]

(b) From the Royal College of Surgeons of England —

Royal College of Surgeons of England,
Lincoln's Inn Fields, London, W.C, May 2nd, 1904

[illegible]

H E Allen, Esq, Registrar, General Medical Council.

*** The information as to the courses of instruction and first professional examination is identical with that from the Royal College of Physicians.

(c) From the Royal College of Physicians of London, inclosing a copy of the full regulations of the Examining Board in England as now revised:—

Royal College of Physicians, London, S.W., May 13th, 1904.

DEAR SIR,—Referring to my previous letters for a statement of the [illegible] oidable delay in the [illegible] reply to the letter [illegible] essed to myself as [illegible] port of the visitors [illegible] try, physics, and [illegible] *United Kingdom* [illegible] College. I now [illegible] nation of the Pre [illegible] e answers to them in a parallel column adopted at a general meeting of the Fellows held yesterday May 12th.

[illegible]

I am, dear Sir, faithfully yours,
EDWARD LIVEING, M D, Registrar.

H. E Allen, Esq, Registrar.

Sir VICTOR HORSLEY moved:—

That the cou [illegible] Examining Boa [illegible] London and of [illegible] in March, 1905, a [illegible]

He said that he felt it was his duty to put this motion on the paper because in a previous session he had made a proposal which the Council agreed to—namely, that the then courses of study and examinations of the Conjoint Board in England were insufficient. This session they were given to understand in the course of discussion that the Conjoint Board of England was considering this matter and that it had already published a kind of preliminary account of what it meant to do. It was obvious that the preliminary account satisfied the members of the Council to a very large extent. At any rate, the matter proceeded no further at that point. They had now before them these new regulations and the synopses relating to them. They ought not, as they seemed to do the previous day, to regard the synopsis and a course of study as synonymous terms. The synopsis was only part of the documents relating to the course of study. The previous day he had been interrupted by Dr. Norman Moore when he spoke of the requirements of this Council in the arrangements of the curriculum. Dr. Norman Moore had corrected him and said "recommendations," and he had accepted it at the time. Dr. Norman Moore, however, knew perfectly well that the word used by the Council in the details of the curriculum was "requirements."

Dr. NORMAN MOORE: No, I do not.

Sir VICTOR HORSLEY said that in that case he was sorry to say that Dr. Norman Moore did not know the principal document of the General Medical Council which laid down what the Council "required" in the curriculum—subjects, courses of study, and examinations. This document was their Magna Charta. It began: "A. The requirements in regard to professional education," and with regard to the course of study and examination the Council "required," &c. The same document in the second part had a few recommendations of the Council relating to practical work. This Council was the supreme authority in medical education and all he had to say was that the course of study and examinations were "required" by the Council. That governing the position, as it appeared to him, they might proceed to look at the communication from the Royal Colleges. The communication consisted of two parts. It dealt with the course of study and with examinations. His motion only related to the first part—the course of study—because he personally was quite satisfied with the details of the examinations. They coincided with what the Council passed the previous day. The courses of study were to fit the student after he was registered to show that he was possessed of the requisite scientific knowledge. In resolutions 3, 4, 5, 6, and 7 they found embodied the opposite of what he expected to see after the discussion of last session. At the last session he really thought from what fell from Dr. Norman Moore and Dr. Windle and others that a kind of *modus vivendi* had been arrived at in the minds of members of the Council, but they found here, with one exception, precisely the point which the Council had taken exception to in the past and had voted against again and again. In other words, all the previous debates of the Council and all the money of the profession which had been expended on this question were thrown away if these regulations were now to be accepted by the Council as adequate. Taking No. 3, which said that these courses of study need not run concurrently nor be completed within one year, he submitted that in other words the students might begin at any age—at ten years of age if they liked. The next resolution said that these courses might be commenced or attended before the required preliminary examination in general education was passed. He was quite sure that he was reflecting the opinion of the majority of the Council when he said that they laid down that the curriculum of education for the medical student should be divided in an orderly manner, that he should have done with his preliminary education first, that then he should take his general education, and after being done with that he should go on to his anatomy and physiology and so on. The Council had therefore decided against this No. 4. No. 5, which stated that study at an institution other than a recognised medical school be counted for not more than six months of the curriculum, was the only concession which the Colleges had made, but it did not affect the general issue. Pointing to No. 6 resolution he remarked upon the difference which the Colleges were making in their treatment of the scientific education of the student on the one hand and his education in anatomy and physiology on the other. The Colleges said that anatomy and physiology were not to be recognised, or in other words not commenced until the scientific part of the education was got rid of. Precisely the same treatment ought to be meted out to the scientific part of the education if it was of equal importance. If the Colleges took the line that it was not of equal importance that would be a legitimate position, but the Council had decided in the opposite way. With regard to the seventh resolution they had it stated again that the curriculum, as the majority of the Council understood it, was definitely to be evaded by the Royal Colleges. It was not to be any longer five years of study but four and a half years. He would not labour that point as it had been discussed in detail by the Council. Coming back to general principles, it was clear that these regulations violated the principles which the Council had laid down after wearisome and prolonged debates during a period of ten years. He therefore submitted that whatever step the Council took in regard to preliminary scientific education it ought not to accept these regulations as being sufficient.

Sir WILLIAM THOMSON seconded the motion.

Dr. MCVAIL, after drawing attention to several resolutions come to since 1894, said that the great point of dispute had been that the English Royal Colleges were admitting men who were taking their scientific course before they had passed the preliminary examination. That matter was keenly fought for two or three years and the Council in the end gave way and authorised the admission of men who had taken this course prior to the preliminary examination on condition that the curriculum should be five years in duration. The next great subject of dispute was the one regarding the institutions at which those subjects might be studied and it began about 1898. The Council had a few years' quiet on conceding that point to the Royal Colleges and then came in another great subject of dispute which had lasted down to the present time. Sir Victor Horsley would see that the minutes did not bear out his view of the requirements since 1894. He entirely agreed with him in principle that those subjects should be taken after the preliminary examination was passed. That was his own personal opinion but the Council for nine and a half years had practically conceded the point to the Royal Colleges.

Dr. MACALISTER said that he thought it was desirable to emphasise three points on which a new departure had been made by the Royal Colleges. It was important to consider whether or not the substance of all that they had been con- tending for had now been obtained, even although the form in which it was presented might be different from what they had originally desired. First of all for the first time the length of the minimum course of instruction in chemistry, physics, and biology was prescribed. The discussion between the Colleges and the Council as to what should be preliminary scientific instruction, whether it should be ordinary school work or special lectures at a medical school, turned very largely on the question what was the kind of instruction that was given at ordinary secondary schools and whether the instruction received by the boys was adequate. On that point the inquiry made by the Education Committee seemed to afford evidence that much was still to be desired in the requirements of the Royal Colleges in this respect. It appeared that in some of the schools which they recognised the number of hours given to a subject per week was not such as to insure to young students a thorough acquaintance with the subject. Now a minimum course of 180 hours' instruction and laboratory work in chemistry, 120 hours in physics, and 120 hours in biology was to be the *sine qua non* of the recognition of any such course of instruction. Looking to what happened in ordinary medical schools and in universities and other insti- tutions of higher instruction he should have no hesitation in saying that that minimum course was at least equal, and in many instances superior, to what at present was received by the ordinary medical student so far as duration was con- cerned. The second point was that if the boy spent three years in doing his course he would get credit at the very most for six months. It was true that he might pass this scientific education examination immediately after the preliminary examination, but that was permitted by the Council's regulations and was not contrary to any- thing the Council had laid down. The Colleges had gone further than that and laid down the regulation that until the student had passed his examination in chemistry, physics, and biology no study in anatomy and physiology would be recognised at all. On the whole, although they had not formally put themselves exactly in line with what the Council had put down, their conditions were more drastic than what the Council would have been prepared to regard as a minimum. It would be grossly unjust to say that these conditions were insufficient. They might not be perfectly happy in their form but they certainly could not be regarded as insufficient in severity or comprehensiveness.

Mr. BROWN said that although some of them might agree with Regulation No. 3 many of them would disagree with Regulation No. 4, which stated that the courses might be attended before the preliminary examination was passed.

Dr. NORMAN MOORE: That is a regulation of the Council.

Mr. BROWN said that to his mind it was one which should not exist. He would be glad if the sense of the Council were taken on the point.

Dr. WINDLE said with regard to the meaning of the word "require" it appeared to mean this, that when the Council laid down something as a requirement and it was not carried out they were at liberty to report the body to the Privy Council. That was what was meant by "requirement" and nothing more. The courses of instruction of the English Royal Colleges appeared to meet a great many of the difficulties which had been previously felt. One which previously appealed to him was that in the recognised institutions apparently no definite instructions as to length of course or nature of course were given. Those institutions had now full guidance. The only thing he regretted was that some regulation had not been laid down as to the length of time over which this instruction might be spread. There was something to be said for intensity of instruction as well as length of instruction. Looking at the regulations from the common-sense point of view it was extremely unlikely that a boy would come up for examination in chemistry and succeed who had spread his 180 hours over six years. He would require to be a very brilliant boy. The Council now got from the Conjoint Board a great deal more than they got from the University of London about which there was no complaint. After passing the preliminary examination of the University of London the student might attend for instruction anywhere or nowhere. He might work in a back attic. It was not laid down that he was to go to any institution or to receive instruction of any particular length. Of course, the answer was that the position was covered by a hard, severe examination, but to his mind that was no answer. The curriculum was the important thing. He saw no reason to regard the instruction which was demanded by the Conjoint Board as other than sufficient. It was perfectly true that a student might obtain his qualification in four years and six months, but this period was more likely to be six years and four months. Although the regulations of the Colleges did not in every respect conform with the letter, they more than conformed with the spirit of the finding of the Council and he could not, therefore, support the motion.

Sir CHRISTOPHER NIXON said it was not necessary to labour the reduction of the five years. The course of instruction and examination in connexion with the first year's course of study was more than adequate for the ordinary medical student. It was more than any other examining body in the United Kingdom required. The number of hours in connexion with physics, chemistry, and biology afforded a marked contrast with what was required in the Royal University. The position of the Colleges was very favourable for medical education in respect of the fact that physics, chemistry, and biology might be taken up before passing the preliminary examination and the over-burdened curriculum might thus be lightened. By the tables presented by the Examination Committee they had been shown that in the great majority of instances the student did not go to medicine until he had reached his nineteenth or twentieth year. Assuming that he had chosen medicine for his profession at 16 or 17 years of age what, he asked, was the boy to do in the intervening years? In those years there was ample time to take up the subjects of physics and biology and a certain amount of useful chemistry. If they allowed a boy after passing his preliminary examination to present himself a month or two afterwards for the preliminary scientific examination then he would have all his time at his disposal to devote himself to essentially medical subjects. He thought the differences between the Colleges and the Council were very trivial and that the action of the authorities emphasised the principle, which he would like to see generally recognised, of leaving a student free to take out scientific subjects before he passed his preliminary examination.

Dr. MACKAY said that if he read the regulations rightly he could not understand the criticisms. Probably a boy would never begin to study chemistry or biology before he was 16 years of age. He could not think that in substance these regulations transgressed any of the Council's orders. He thought they were in keeping with all that they had laid down in principle at least if not exactly in form.

Sir JOHN BATTY TUKE said that although he was not perhaps in accord with certain of the regulations he recognised the essential necessity of good scientific education. Tremendous efforts had been made by the Colleges to bring themselves into line. He could not say that there was justification for such a motion as was now before the Council.

Sir PATRICK HERON WATSON asked why midwifery had been left out in Resolution 7, which stated:—

> That no student be admitted to examination in medicine and surgery until he has completed five years of professional study, &c.

Dr. NORMAN MOORE said that no alteration whatever had been made in the regulations about midwifery.

Mr. MORRIS said that the midwifery examination could be taken before the expiration of five years but, of course, no one could get the diploma until he had passed the whole examination in medicine and surgery.

The PRESIDENT said he was under the impression that the manner in which this question had been interpreted by the Council was that those three subjects were to be the subjects of the final examination.

Dr. NORMAN MOORE: So they are.

The PRESIDENT: Do you divide your final examination into two parts with the intervention of a year between midwifery and surgery?

Dr. NORMAN MOORE said that was not compulsory. The regulations were sent to the Council every year and if the arrangement was not legal he had no doubt the Colleges would alter it.

Dr. MCVAIL thought that the matter was quite clear in the regulations. At the English Conjoint Board candidates might present themselves for midwifery at the completion of the fourth year but they could not present themselves for examination in medicine or surgery until the completion of five years. That was their custom. Perhaps the Colleges might be continuing some old arrangements but he thought as Dr. Norman Moore's attention had been called to the matter he might look into it.

Dr. MACALISTER recalled the fact that this matter was discussed in 1890 and the legal opinion obtained then was that there was nothing to prevent the authorities from separating the examinations on the three subjects and holding them at different times.

Sir WILLIAM THOMSON said that it was because he was in entire accord with the spirit of the motion that he had seconded it. The matter to which it referred was an old and very painful story and as a very young member of the Council he had protested against the action which these two English Colleges had taken in assuming a position hostile to the views and rules which the Council had laid down and which they insisted that other bodies less strong perhaps and less pugnacious should carry out. That always seemed to him an extravagant position and as the Council knew the matter had come up year after year. What was the position they were in now? Those bodies after telling them last year that they were bringing in a scheme which would satisfy the requirements of the Council had brought in a scheme which, although he had heard some members say was entirely satisfactory in the spirit, still allowed them to maintain a position of independence with regard to the Council. The Council had either power to deal with educational matters or it had not. If it had power to deal with educational matters then some respect ought to be paid to the views which it from time to time expressed and which it submitted for the guidance of the licensing bodies. Some who had spoken maintained that the Colleges were now ready in spirit to do a great deal more than the Council had ever required. He would not assent to that view. The bodies came in, not surrendering at all, but thinking that the Council having admitted their rules on other occasions would accept their regulations now. That was not a satisfactory condition of things. If there was to be a perpetual wrangle over the instruction in the preliminary scientific studies it would be better for the Council and the various bodies, and also for the higher education of the students, that those subjects should be made the subjects of an entrance examination and the professional education limited to four years. Of course, he was glad that to the minds of several members of the Council who had spoken there had been an approximation to the rules of the Council with regard to these subjects. He still held that the Colleges had not taken the attitude in relation to the Council which ought to be taken. The Colleges were two old and distinguished bodies. They ought to be the leaders in acquiescence in the judgment of the Council. They ought not to set the example of resistance to its regulations. The suggestions of the two bodies would be always considered. The Council wanted to arrive at a scheme which would be best for the development of medical education and he hoped that all would come into line in the matter.

Dr. **BRUCE** said that he was going to vote against Sir Victor Horsley's motion and he did so from the point of view that he thought this was not a question of fighting or anything else. The less they heard of any autocratic demands by the Council the better.

Sir **VICTOR HORSLEY** remarked that six months ago members said that the instruction in the preliminary scientific subjects at the recognised schools was not sufficient. If they voted against his motion they would be saying that it was sufficient.

Dr. **MCVAIL** said that whilst he would vote against the motion he was giving no opinion as to the schools in which those courses of study would be carried on.

Sir **VICTOR HORSLEY**, continuing, could not admit that this question of teaching institutions was a trivial matter. The Council was still exactly in the position which it had been in, as the Colleges could recognise any school they liked. They could demand any preliminary examination they liked and they could recognise it without any reference to the Council. The situation with regard to medical education, which was looked upon with great gravity six months ago, was still to his mind a subject of great gravity.

On a division, six members voted in favour of Sir Victor Horsley's motion and 22 against it. It was accordingly declared lost. Three members did not vote and one was absent.

Mr. **BROWN** then moved

> That the new scheme of courses of study under the new regulations of the Examining Board in England by the Royal College of Physicians of London and of the Royal College of Surgeons of England be referred to the Education Committee for examination and report.

Dr. **BRUCE** seconded the motion.

On a division 11 members voted for the motion and 13 against. It was accordingly defeated.

Visitation of Preliminary Scientific Examinations.

Sir **PATRICK HERON WATSON** moved that the following recommendation by the Examination Committee should be adopted by the Council:—

> That the Council complete the visitation of the preliminary scientific examinations held by the bodies mentioned in Schedule A by appointing visitors to visit these examinations in the universities.

Dr. **MCVAIL** seconded the motion.

Dr. **MACALISTER** thought that the present time was inopportune for making this proposal. The Council had just passed a number of recommendations as to what subjects preliminary examinations in science ought to include. It was probable that changes might be made in some examinations in consequence of the communications which would be sent out by the Council. Time should be given for these changes to be introduced. In these circumstances he thought they might postpone the visitation until next year.

Dr. **MACKAY** considered that there was no necessity at the present moment to have a system of examining the preliminary examinations. He thought that the Council should inspect final examinations, but only from time to time on occasions when it seemed necessary should they carry out the inspections of others.

Sir **JOHN BATTY TUKE** said that he had sufficient confidence in the universities carrying out their work and he thought that it was unnecessary to go to the trouble and expense proposed in the motion.

Dr. **NORMAN MOORE** remarked that when this matter was taken up by the Council it was intended to review the whole subject of examinations. He thought that even if they were put to some inconvenience and expense they ought to go through with the work which they definitely undertook.

Dr. **LINDSAY STEVEN** agreed that it would be little less than an injustice if the inspection was not carried through to the end.

Dr. **MCVAIL** said that they had visited the examinations of the corporations and certainly it was a most extraordinary thing that Dr. MacAlister should propose that they should not examine the universities also. He hoped that the Council would be quite consistent and carry the policy through.

Dr. **PYE SMITH** protested as treasurer against the proposal as extravagant. He confessed that the series of inspections which they had gone through had had good results. However he did not think that the further inspection which was proposed was necessary at present. He thought that in view of the financial statement which he had to present they should not spend money now on this object.

Dr. **MACALISTER** then formally moved as an amendment:

> That the visitation of the university examinations in chemistry, physics, and biology, be not continued until after the inspection of the final examinations is completed.

Dr. **WINDLE** seconded this amendment.

Sir **VICTOR HORSLEY** submitted that the Council ought not to consider the expense when they were dealing with a matter of importance in the curriculum. He hoped the amendment would not be carried.

Dr. **FINLAY** said that he saw nothing inconsistent in approving of both the motion and the amendment. They might pass the motion and add the amendment to it.

On a division 19 members voted for the amendment and 10 against it. Dr. MacAlister's amendment was accordingly carried.

When put as a substantive motion the amendment was adopted by 19 votes to 10. Two did not vote and one was absent.

Suggested Uniform System of Marking.

Dr. **MCCALL ANDERSON** moved—

> That the Registrar be instructed to communicate with each of the licensing bodies, recommending a uniform system of marking in all cases in connexion with their examinations.

He said he was not aiming at a uniform system of examination. That was not possible. If it were possible he questioned whether it would be desirable. Each licensing body should be entitled to carry out the details of its examination as it thought best, always subject to the approval of the Council. But what he wanted to direct attention to was the great variety in the systems of marking that were adopted by the various licensing bodies. A uniform system would, he submitted, be a great convenience, and he thought that the best would be a percentage system, that each subject should have a special mark. If a man passed a perfect examination let him have 100 per cent. and 50 per cent. could be a pass mark.

Dr. **BRUCE** seconded the motion.

Dr. **MACALISTER** proposed as an amendment:

> That the question be referred to the Examination Committee for consideration in connexion with their final report on the completion of the cycle of visitation of inspections.

Sir **CHARLES BALL** seconded this amendment.

The **PRESIDENT** pointed out that in 1895 the Council passed a motion for the adoption of a uniform system of marking. That had been on the minutes of the Council for nine years and what had been the result? *Nil.* And he ventured to say that if the motion was re-affirmed now the result would again be *nil.* It must be left to the different examining bodies which had the experience to guide them to decide whether in their judgment a man was competent to pass or not. As an old examiner—for he had been engaged for 40 years in examining and thousands of students had passed through his hands—he might be permitted to say that the only thing that was in his mind when a man came before him for examination was, "Is that man fit to pass or not?" It would be quite absurd to go into all the minutiæ of marking.

Sir **VICTOR HORSLEY** claimed to say a word for the poor student. The object in having a uniform system of marking was that justice should be done. Without some definite system they could not say that one man was not obtaining the privilege of entering upon the Register on more easy terms than another.

Sir **PATRICK HERON WATSON** said that to lay down a strict rule to be followed by every examining body would simply be an act which would make the Council jeered at by all these bodies.

Dr. MacAlister's amendment having been withdrawn leave was given, after a show of hands had been called, for the withdrawal of the original motion.

Instruction without Examination.

Dr. MACKAY moved :—

> That the Education Committee be requested to collect information and report on the subject of the possibility of including certain subjects in the curriculum without requiring examination in them.

He said that on the previous day it had been suggested that this subject should be referred to a committee with the view of action being taken on an early date. And as the question was in a way discussed on the previous day he did not consider it necessary to go once more into details. He trusted that the question would be discussed outside and that all the bodies concerned in medical education would sooner or later take up the matter and deal with the whole question of the overcrowding of the curriculum and the great pressure upon students at the present time. It was an important educational question and he had thought it right that the Education Committee should be asked to find out what was being done in other countries and by other teaching institutions in this country.

Dr. NORMAN MOORE seconded the motion. The subject was worthy of discussion. Whether it was practicable or not could be proved.

Dr. MCVAIL rose to ask a question. What were the "certain" subjects?

Dr. MACKAY: Whatever subjects which it may be found possible to include.

Dr. MCVAIL: That means uncertain subjects. It is absurd to talk about certain subjects when the whole thing is uncertain.

Sir JOHN BATTY TUKE said he did not think it would be possible to define the subjects.

Dr. LINDSAY STEVEN said he would vote against the motion chiefly upon the ground that the matter was decided on the previous day when Dr. Finlay's proposal was rejected.

Dr. MCVAIL said that the proposal would only unsettle the minds of teachers and students.

On a division the motion was carried by 13 votes to 11. Four did not vote and four were absent.

The Council then adjourned till Monday.

* * *

MONDAY, MAY 30TH.

The Council resumed its deliberations on Monday, Sir WILLIAM TURNER presiding.

The Registration of Medical and Dental Students.

The first business on the notice paper was a motion by Sir John Batty Tuke regarding a Bill for the registration of medical and dental students.

The PRESIDENT said that before this was taken up he thought it was right that he should make a preliminary statement so that the members of the Council might be in a position to know what was the state of matters at this moment. As that statement would require him to call attention to certain official communications that he had had he thought he should make it *in camerâ*.

The statement was accordingly made in private and when the public were readmitted the business was proceeded with.

Sir JOHN BATTY TUKE moved :—

> requested to intro-
> ral Medical Council
> ers of medical and
> [illegible] £1 for registration
> therein.

He said that he desired to support the President's opinion given *in camerâ* regarding the position taken up by the authorities of the Privy Council. It was that the adoption of a registration fee for students was the most convenient way of adding to the resources of the Council. But apart from those authorities he had consulted men versed in affairs and without exception they had given the opinion that the Privy Council having made the statement which it had made to the President in this matter, it would be advisable for the Council to follow the advice of the Privy Council. They recognised that the line taken by the Privy Council was one of the least resistance, and they advised him personally that the proposal of the Privy Council was the most likely one to meet the objects which the Council desired. For these reasons and for others which he would give he had tabled this motion. The proposal required to be regarded from two points of view—firstly the monetary, and secondly the administrative. As to the monetary point, the report of the Finance Committee of the Council was not altogether a satisfactory document; in fact, it would be easily seen that the Council, if matters went on as at present, was within measurable distance of bankruptcy. He had taken the five years ending 1903 and he found that during those years the average excess of expenditure over income was £1525. In other words, during those five years they had eaten into capital to the amount of £7500. No one doubted that money must be got somewhere. They had of their own motion exercised certain economies, they had reduced the fees payable to members, and they had added extra fees to certain registrations which it was within their power to increase. Might he also be allowed to express the hope that in the next few years they would have a stoppage of the cycle of inspections. In the cycle almost concluded they had had very good results; bodies that were criticised had accepted the criticisms in the best spirit and had either introduced reforms or intimated their intention of doing so. There were two means of increasing their receipts—the increase of fees and the economies they had exercised in their own arrangements as a Council. If the Council accepted the proposed Bill and that Bill passed, the Council would be in receipt of an increase of revenue of £1700. That was a low calculation. He based it upon the fact that in each of the five years ended 1903, 1715 students registered—1518 in medicine and 197 as dental students. But he had a strong suspicion that he might place the receipts somewhat higher than £1700, for judging from the evidence of a report which he would submit later he thought that a not inconsiderable number of students neglected registration. He found that in England there were 629 students registered and 568 in Scotland—a difference of only 61—and he was not aware of any material increase of students in Scotland nor of any decrease in England to such an extent as was indicated by these figures. He might be wrong; if he was wrong there was all the more necessity for this Bill, but however he was quite content to base his calculation on an increase of receipts of £1700. He believed that in the economies made and the extra fees which they had charged they would be able to produce a surplus of between £1000 and £1200, and that money the Council absolutely required. They must in the next few years lay up a surplus in order to perform their statutory duties and for other purposes, and amongst those other purposes they would probably require more money for the Pharmacopœia. At present they were dependent to a great extent on almost gratuitous services and that placed the Council in a somewhat false position. Now as to the tax upon students. Was it fair or unfair? He held that it was a reasonable initial expense, for it must be remembered that the Council even in existing circumstances went to considerable expense in the matter; they had to maintain a staff, to print schedules, to print regulations, and to keep a students' register. That all cost money and it came out of the pockets of the practitioner. He had thus roughly foreshadowed what would be the effect from a monetary point of view. In the second place he would state his opinion as to what would be the effect administratively. In the first place the Council would by legislative enactment be made responsible for the carrying out of the registration of students, and being so it would be the duty of the Council to lay down conditions. The power of laying down conditions would be an absolute *sequitur* to their obtaining power to register students. Now what would the Council gain and what would it lose? It should gain a certain assurance that its first and principal and great requirement—the study of medicine for five years after registration—would be complied with by all. At present the Council had no official assurance that this chief requirement was complied with in the case of students who neglected to register. Secondly, the Council would be able to assure itself that each student had passed a satisfactory examination in Arts. Thirdly, the Council would have the power of approving or disapproving of those institutions recommended by the various bodies at which medical study would be begun. The Council would be able to put into force what it at present laid down as requirements, which were not universally followed. In plain terms, there would be compulsory registration under the Council's conditions. Every member of the Council would admit that such a state of things would be convenient to the Council, to the profession, and to the public and after all the public was a part of the community whose interests required to be looked after carefully. He did not expect that everyone would agree with him on this matter beyond convenience. But he should like to ask what the licensing bodies would lose. When he said licensing bodies he meant every one of them. They would merely lose in two matters—the right to nominate educational bodies whose examinations in general education were accepted by them and the right to nominate bodies at which medical education could be begun. In no other respect whatever would the autonomy of any individual body be interfered with. And when they came to consider the important bearing of such a measure on medical education at large he asked was it worth while fighting for the supersession of such comparatively unimportant matters? All cases of friction would disappear. The poor student would not be bewildered between his duty to the Council and the body whose school he might attend and all bodies would come into line on equal terms. There was one other point. It was extremely likely that the motion might be met by a suggestion for delay—a suggestion that the bodies should themselves be first consulted. He hoped the Council would take the ordinary constitutional method of passing or rejecting the proposal. If it was passed each licensing body could express its opinion on the action of its representative and it would also be left to each body to take action to further its interests when legislation was proposed.

Sir Victor Horsley seconded the motion. He said he wished to speak in support of the Bill solely from the point of view of the material interests of both the professsion and the public. Everyone interested in medical education knew that the registration of a student was an essential of the perfection of the medical curriculum. That essential had been wanting hitherto and this motion proposed to provide it. The autonomy of the licensing bodies was not touched at all. These bodies had no autonomy in the Council. By the Act of 1886 it was hoped that the individual interests of the licensing bodies would be harmonised or if necessary suppressed in the Council's discussions and that the decrees and laws passed by the Council would represent the feelings of those who were anxious to advance medical education independently of the autonomous interests of any licensing body. That was the feeling of the profession at large.

Dr. Payne said that there were one or two points which possibly might not have received sufficient attention. It was entirely a good thing in general that every medical student should in some way make his existence known to the Council and be recognised. But he did not quite see that compulsory registration would give the Council unlimited power of fixing the conditions of such registration. There was only one method of making it compulsory and that was to lay down that unless a student registered himself at the proper time and under proper regulations he should not be admitted to final registration as a practitioner when he had passed the examinations. Unless that was put down absolutely in black and white in the Act of Parliament he did not think that the Act would have any force at all. It seemed to him that it would be a very good thing if they could once for all simplify the question of preliminary education by saying that only one authority—that was the Council—should lay down what was the preliminary education for a medical student. He thought that they should have power in an Act of Parliament to refuse to register any student who did not show evidence of preliminary education. That seemed to him a reasonable course, but, on the other hand, he did not think they should try to control the course of the student beyond that. If they wanted to use power of that kind it must be literally defined and, in his opinion, they ought not to go too far.

Dr. Norman Moore said that there were two things which the Council wanted to get. It wanted money. That was apparently an immediate and pressing need. The other thing which, speaking from his own time of service on it, it appeared to have even a larger appetite for, was power. Every session that he had sat on it motions had been brought forward to try to increase its powers. The Council discharged under the Act of Parliament a most important duty in maintaining the Medical Register. It discharged certain duties with regard to education and qualification. It had never, however, been given the power of absolute supremacy in every point referring to medical practitioners in the country. He hoped that that power never would be given. The Council had shown an inclination to lay down what it called requirements at every stage of medical examination with regard to what candidates were to be examined in and where they were to study. He thought that the power ought not to be taken from the universities and licensing bodies and given to the Council. There had been a good deal said about licensing bodies not having any particular curriculum of studies. Universities had that curriculum. He believed as a member of a university that it was a better authority to determine what was best for the students of its several faculties than a body like the Council. The University of London had arrived at a decision as regarded its matriculation examination. The General Medical Council had said that it would not recognise that as a sufficient education for men about to commence medical studies. Unless the student who had passed this examination of the University of London could produce in certain circumstances further evidence of education he would not be acceptable to the Council. He thought that was a good example of how the Council would take it upon itself to dictate to the universities.

The President said that Dr. Norman Moore stated his argument rather too strongly about the University of London.

Dr. Norman Moore explained that the student who wished to matriculate at the University of London had a choice of subjects. Supposing he selected a group not containing a subject or subjects required by the Council and passed it the Council would not admit him. Fortunately this power of the Council was at present limited. This desire for increased power on its part ought to be resisted. Now what would the student get in return for his sovereign registration fee which was proposed? Nothing at all. What would the public gain from it? Nothing at all. It would be a sovereign taken in the Council's own interests and for its own purposes. He opposed this proposal because it would give to the Council a power which by its own acts it had already shown ought not to be given to it and because it proposed to impose a fee upon students without giving them any return.

Sir William Thomson remarked that the Council had heard itself painted in very strong colours. The members had been described as if they were a lot of bandits setting out to assault the unfortunate but innocent student and to extort a sovereign, not for his benefit and not for the benefit of the public, but for the benefit of members of the Council. That was an aspect which had hardly been justified by the speeches of the proposer and seconder of the motion. Dr. Norman Moore had said that there had been a cry for money and an insatiable desire for more power. He hoped that the Council recalled the proceedings of Saturday and observed the attitude of the representative of the English College of Physicians. The speech which they had just listened to was of the character of a manifesto which would perhaps be adopted by other bodies in their relation to the Council. This was a rebellion against what he would call the powers which were conveyed to the Council by Act of Parliament. What scheme had Dr. Moore brought forward to the Council by which the deficit would be made up?

Dr. Norman Moore said that the scheme he was prepared to support was that members of the Council should not be paid. That would save a very considerable sum per annum.

Sir William Thomson, continuing, declared that he was not one of those people who believed that work which was well done should not be paid for. Work had been given to the Council by Parliament and the way by which it was to raise funds was by charging fees to the practitioner who had just passed his examinations. He did not think that the collection of an annual fee from practitioners was feasible but upon all grounds the method which had just been proposed was one which ought to commend itself to the Council. He did think that it was unfortunate that the Council, representing all the licensing bodies of the country and the general profession, should be described as a sort of insatiable monster seeking to get into its grasp the whole control of the profession. He would venture to say that the Council, composed as it was of men who now were, or had been, medical teachers knowing the practical wants of the student, was able to discharge its duty as no individual licensing body could do.

Mr. Morris said that really there were two matters involved in this discussion. One was the control of the licensing bodies over the preliminary courses of study which they should adopt and over the schools from which they should accept certificates. The other matter was to place a tax of £1 upon the medical student. These had to be considered together. He could not help saying that in his opinion this attempt to get compulsory registration, accompanied with the charging of a fee, was a backstairs way of getting the other object the Council had in view—namely, the control of early education and the control over the bodies which had been recognised by the institutions. On the question of the expenditure of the Council, he pointed out that on some occasions its time was occupied by unpractical discussions. Those sittings, however, involved considerable expense. For instance, nothing bearing upon the essential work of the council had accrued from the discussions on Friday and Saturday. The effects of passing this motion would, he felt, be to threaten the chartered rights and powers of the licensing bodies. The motion would have to meet with their opposition. In saying this he wished to say that it was the desire of the council of the College which he had the honour to represent to consider with due deference and respect every suggestion that came to them and to consider it carefully and fully. He was quite sure that there was nothing which that Council or any member of it would be less desirous of doing than taking up a position of hostility to the General Medical Council. There was nothing they desired more than to act in consonance and in harmony with the Council. The attitude of his College to the Council was simply, so far as any opposition was concerned, one of defence and not one of defiance. He felt it necessary to oppose the motion because he thought a better method could be adopted of raising funds. He was afraid that the imposition of a fee of £1 would not be sufficient for the income desired to be raised, while the tax would cause serious contention amongst the licensing bodies.

Dr. BENNETT opposed the motion as it stood. The Council, for example, had no right to restrict the rights of the University of Dublin with regard to its students. The question had never been raised but he was quite sure that the governing body of Trinity College would oppose the imposition of a tax of £1 on every medical student.

Dr. MACALISTER said that he should prefer to have raised the fee of the medical practitioners to imposing a registration fee, but the choice not having been given to him he could not say that he would oppose the proposal in its present form. He thought they ought not to refuse this source of revenue if it were obtainable. That was his reason for believing that the Council should accept the motion of Sir John Batty Tuke. The motion would also give to them constitutional powers to establish a register of medical students. That seemed to him to be the logical completion of the powers given to the Council by the Act of 1858. *On the mere point of view of making registration* complete and significant he could not help thinking that the members of the Council were justified in asking for power to establish a students' register. They were advised by their lawyers that they had power to establish anything for the carrying out of the Act, and in setting up a students' register they could refuse to register a diploma to any student who had not registered. Of course, an appeal to the Privy Council on the part of the student was possible. They in Cambridge, he continued, did not regard the Council as an external body greedy of power and grasping at functions which it was not entitled to exercise. They regarded it as the only existing inter-university board in the kingdom. It was the only board that he knew of where representatives of all the universities met and took counsel together on matters which were of common interest to them all. Round that board they had the representatives of the great licensing corporations, of the Crown and of the profession and he could not imagine a body more entitled to speak on points such as those raised by Dr. Moore and Mr. Morris. As to the University of London, it had been dealt with in the same way as other universities in the country. He was prepared to support the motion.

Dr. LITTLE said he could perceive that there would be *some difficulty in carrying out the details of the proposed* scheme but he was prepared to support the motion. If it were only a question of raising money he would not do so. He had always felt that one of the most important things was to ascertain when a student began his studies and whether he was fit to begin them at the time. The Council had never exceeded its proper functions in regard to supervision and advice. He thought that some of the bodies which he would not mention had not shown a proper attitude in resisting their advice.

Sir CHRISTOPHER NIXON said it had been a matter of disappointment to him after the period of storm and stress through which the Council had passed to hear the observations of Dr. Moore. Dr. Moore had represented the Council as a number of caterans who desired an amount of money for which they gave no value and who were grasping for power. With what object were they grasping for power? They were grasping for power to try to secure a body of men who would be entitled to be put upon the Register. They made regulations of a minimum character which would apply to all students of medicine. There was no desire or intention on the part of the Council to interfere with the rights of corporations or to interfere in any way with the regulations which the universities might make with regard to their own branches. They did not ask more than that all the men who passed and were entitled to be put on the Register should be sufficiently educated. The requirements *in regard to the subjects of the preliminary scientific* examinations had been to a large extent complied with by the Royal Colleges and the differences between them as to institutions recognised or approved by the Council had come to a vanishing point. Now, it seemed that the action of the Colleges by some indirect and, as the word had already been used, backstairs method in opposing Sir John Batty Tuke's motion was to secure a right which was not to be exercised by any other bodies in the Council. He regretted that the struggle between the Colleges and the Council seemed to be emphasised by the tone assumed by the representative of the Royal College of Physicians of London. He hoped the motion would be carried without delay as no advantage could be gained by sending it to a committee. He strongly urged the Council to accept the proposal inasmuch

all the bodies represented in t

wisdom of all the universities an

be superior to that of a small minority and no regulation *inimical to the interests of the profession* was likely to be passed in the Council in face of the representations of those different bodies and interests. What had helped to put the Council in the high position which it held both with the profession and the public was that all its enactments had been made in the interests not of any merely local corporation or university but in the interests of the profession at large.

Dr. PYE-SMITH intimated his intention to vote against the motion on purely financial grounds if on no others.

Dr. MACKAY regretted deeply that opposition had been offered to this motion by representatives of the Royal Colleges and others because if they studied carefully the proposal before them they would see that there could be no attempt to interfere with the rights and privileges of any of the licensing bodies guaranteed under the Medical Act. All that the motion asked for was that a duty which this Council had undertaken on its own responsibility might become a statutory duty imposed on the Council by the law. *Actually the only fundamentally* new fact in the whole situation was that it was proposed to enable the Council to charge a fee. The students' register would not take away from the bodies the right to have their own standard and length of courses. No powers would be taken from the licensing bodies *but the Council would find it easier to do* the work which the Government had laid upon it. He would therefore support the motion.

Mr. BROWN agreed with the terms of the motion. It was obvious that it was an oversight in the Act of 1858 that the registration should not be in the hands of the Council.

Sir JOHN MOORE said he intended to vote for the motion. Up to the present the Medical Acts had been distinctly defective in not giving the Council more power in regard to the registration of students. Registration meant that they would know about the ages of students, where they had been taught, and their antecedents. Education began at school and the sooner the General Medical Council was brought in contact with those young men the better. Law students were registered and had to pay a registration fee. He did not regard this payment as a grievance to the student. It would come out of the pockets of his parents or guardians who would like to know that their sons were being looked after by registration. It was an insignificant tax which would not amount to much more than ¾ per cent. of the money paid for medical education.

Sir HUGH BEEVOR, in supporting the motion, thought the fee was not an unreasonable one. It was unfortunate, he said, that this question should be strongly opposed by representatives of bodies which had recently done far more than the Council had asked them to do in other directions.

The PRESIDENT asked the Council to allow him to speak on this question because he had been intrusted with the making of certain important statements to the authorities in the direction that he had indicated in his preliminary remarks when the Council sat *in camerâ*. It seemed to him that some of the arguments which had been advanced against the motion were not applicable to the motion, but to what was considered might be the nature of the Bill. It rested with those who framed the Bill to specify in that Bill exactly what the statutory powers meant. All they were asking at that moment was that a Bill should be introduced into Parliament to confer on the General Medical Council statutory power, but they must wait till the Bill was drafted before they knew what the statutory power was to be. It was possible, therefore, that some of those who had spoken adversely on this motion had spoken in terms which might not be in consonance with the terms of the Bill. He did not know what those terms might be. Some members objected to the fee. He thought that a fee of £1 was a very proper fee to be paid by a student on entrance to the study of the profession of which he wished to become a member. It was an initial payment which conferred on him the privilege of becoming a medical student and being entered on the medical students' register.. For his part he could not see that there was any hardship in the imposition of this fee and he did not think that the student or his parents or guardians would consider it a hardship. It was simply an entrance fee which found its way into the purse of the Council and which would enable the Council to conduct its business. They had heard references made to charters and the possibility of this Bill being an infringement of the charters. It was a somewhat interesting matter in connexion with this discussion, and other discussions which had taken place from time to time during some years, that those references to charters proceeded from a very limited number of members of the Council. But the institutions represented by those members were not the only institutions which were in possession of charters. The universities were in possession of charters. Other important licensing bodies were in possession of charters. Yet these universities and institutions were not continually, if he might say so, displaying their charters in their arguments. The whole of this question he had been familiar with from the commencement and he knew what happened at the University of Edinburgh. When it was proposed that there should be established a register for medical students the various bodies educationally interested in the matter who were represented on the Council received the information that the Council was desirous of establishing a register of students on a voluntary principle. It was suggested at the time that whilst the registration was to be voluntary it was hoped that the University of Edinburgh, so far as regarded its own work, would not confer its qualifications upon students and candidates for the degrees unless they were registered. The University acceded to that request. The University of Edinburgh looked at the general interests of medical education and the medical profession. It felt that the general interests of medical education and the profession would be greatly advanced if along with the other teaching and examining bodies it fell into line with the General Medical Council. He thought he was right in saying that from the time when the University of Edinburgh did fall into line in this matter, and it was very early, to the present time it had loyally acted up to the decision it then came to. They should keep in view that there were things beyond what could be contemplated in a charter of many hundred years ago. The medical profession had not been standing still since those ancient charters were made out. The medical profession had been advancing on great and important lines and he should like to think that all the great educational and examining bodies that were represented on the Council tried to work with the Council in improving and developing the education of their students. They should all help the Council to see that those who aspired to come within the profession had gone through that preliminary education which the Council conceived to be necessary. It was with a very strong conviction that he had spoken, and he thought the Council ought to move in the direction which was indicated in the motion.

The motion was then put and carried by 22 votes against six.

The PRESIDENT intimated that a copy of the minutes would be forwarded to Mr. FitzRoy for presentation to the Lord President of the Council.

Scientific Education Courses.

Sir VICTOR HORSLEY moved :—

> That the Preliminary Scientific Committee be reappointed and instructed to consider and report upon courses of study in chemistry, physics, and branches of elementary biology.

He said that he wanted more information and he also wished to draw attention to the fact that the Preliminary Scientific Committee had collected in its report a large number of facts but had not given them its view of those facts in a digestible form. The institutions as a whole had reported in favour of the biological system that was being conducted, but the teachers were not satisfied that the student was a great gainer by the courses actually administered to him. If there was this doubt in the minds of some teachers there was considerable doubt in his own mind.

Mr. JACKSON seconded the motion.

Dr. MACALISTER said that as a member of the committee he did not see what it was the committee was asked to do. It had obtained a large amount of information a digest of which was presented in the report.

Sir VICTOR HORSLEY submitted that no conclusions were drawn by the committee from the information it had as to how far those various courses met the requirements of the student.

Dr. MACALISTER said that the committee had very carefully considered what was being done and it had advised the Council that the subject of elementary biology should be retained in the curriculum. The Council had come to that decision and it seemed to him that that part of the question was closed. If any more information was wanted than that which was in the report he did not see how the committee was to arrive at it.

Sir VICTOR HORSLEY said that the committee recommended that elementary biology was to be retained and not a word of indication was given of what was meant by elementary biology. Many of them thought that considerable change should be made in the mode of the course of study but the facts produced by the committee were in confusion and disorder. They had not been tabulated; they had not been considered, and they had not been reported on by the committee.

Dr. NORMAN MOORE said that the committee considered whether any special resolution as to any particular line in regard to biology should be adopted. The discussions in committee amounted to this, that there were many directions in which biology might be useful and that this was not the time to say that such and such were useful. The conclusion of the committee was that elementary biology should be retained.

Dr. McVAIL said that as Sir Victor Horsley seemed disposed to take trouble to give some guidance in the matter there would be no harm in referring the matter, in so far as it affected elementary biology only, to the Scientific Committee.

The PRESIDENT said he thought that if Sir Victor Horsley would confine the motion to elementary biology the Council would be unanimous.

Sir VICTOR HORSLEY agreed and the motion was adopted in the amended form to the effect that the committee should consider and report "upon courses of study in the branches of elementary biology." Sir Victor Horsley was added to the committee.

Examination of the Apothecaries' Hall of Ireland.

Sir PATRICK HERON WATSON moved that the report from the Examination Committee on the inspection of the final examination held by the Apothecaries' Hall of Ireland in January last should be received, entered upon the minutes, and adopted. He said that all that need be read was the conclusion of the committee which was as follows :—

> The report by the assistant examiners in surgery, acting also as inspectors to the General Medical Council, on the final examination of the Apothecaries' Hall in Dublin in January, 1904, without comment- [illegible] ey "were satisfied [illegible] nducted and with [illegible]." The inspectors [illegible] is sufficient" and [illegible] nspectors.

Dr. LITTLE seconded the motion which was agreed to.

Royal College of Surgeons of England and the Council's Inspector.

Sir PATRICK HERON WATSON moved :—

> That a report from the Royal College of Surgeons of England having reference to the last report of the visitor and inspector on the final examinations of the Examining Board in England be received and entered in the minutes.

The Examination Committee stated that "having already presented a report on this matter which has been accepted by the Council we are not now in a position to discuss the remarks of the Court of Examiners, but recommend that it be *entered in the minutes of the Council for future reference.*"

The document is as follows :—

The Court of Examiners beg to make the following report to the Council :—

t, in addition to the oral
e required to furnish a
, the court do not agree
considerable experience of
nation for the Fellowship
on, proved that the two
to be required have been
discontinuing the single
d. The *viva voce* clinical

ge number of candidates presenting themselves. (*During the year ending June 24th last 766 candidates were examined in surgery at the final examination of the* Conjoint Board.)

no special

Pass mark ...	*6*	*5*	*5*	*5*	*9*	*30*
Minimum ...	3	2	2	2	4	—

Candidates who obtain not less than 30 marks (50 per cent.), provided they do not obtain less than the minimum at any one part, will be adjudged to have passed the examination.

Dr. FINLAY seconded the motion which was adopted.

Sir PATRICK HERON WATSON then moved :—

Mr. BROWN said that this was far *too* important a matter to be tabled *merely for future reference.* It should be *referred to the Examination Committee for further consideration* and a report. He moved an amendment to that effect.

Dr. LINDSAY STEVEN seconded the amendment.

Some discussion ensued but eventually Mr. Brown's proposal was unanimously agreed to as a substantive motion.

Education Committee's Report.

Sir JOHN BATTY TUKE moved that the following report by the Education Committee be received and entered upon the *minutes* :—

I.—AGES OF MEDICAL STUDENTS AT THE DATE OF REGISTRATION.

it the following table
sh the ages of students
at nder which applicants
e *precise date of their birth,*
1st, 1903. *Up to that date satis-*
attained the age of 16 years was
e data at the disposal of the

months.

it might be a hardship to delay the commencement of professional study.

II.—*RECOGNITION OF CERTAIN PRELIMINARY EXAMINATIONS.*

III.—CONFERENCE WITH THE CONSULTATIVE COMMITTEE ON SCHOOL LEAVING EXAMINATIONS.

In accordance with the resolution of the Council on Nov. 24th, 1903, Sir John Tuke and Dr. MacAlister attended a conference with the Consultative Committee of the Board of Education and explained to that body the relations of the Council to the question of examinations in subjects of general education. No official intimation has yet been received as to the conclusions arrived at by the Consultative Committee of the Board of Education on the important suggestion that a system of school leaving examinations for England and Wales should be established.

Dr. NORMAN MOORE seconded the motion which was agreed to.

Students' Registration Committee.

Sir HUGH BEEVOR proposed that the report of the Students' Registration Committee be received, entered upon the minutes, and adopted.

This was agreed to.

The Council then adjourned till Tuesday.

TUESDAY, MAY 31ST.

The reports of the Education Committee and Finance Committee were received and adopted, the latter report showing a deficit on the year's working of the Council of £2165 1*s.* 8*d.*

Mr. Tomes was elected joint treasurer of the Council and the Finance, Executive, and Penal Cases Committees were chosen.

The Pharmacopœia report was received, when on the motion of Mr. JACKSON a resolution was passed in favour of the Weights and Measures (Metric System) Bill now before Parliament.

After debates upon the registration of joint stock companies as dentists and upon the systematic canvassing on behalf of medical men for subscribers to sick clubs, which will be reported in our next issue, the session came to a close.

THE CENSUS OF INDIA OF 1901.[1]

VERY few people in this country realise all that is comprehended in the word India, its extent of territory and varieties of climate, its huge population and the diversities among its peoples, races, and tribes, in language, caste, religious beliefs, habits and customs. But these voluminous reports, which are a very mine of information on these subjects, will give some idea of how stupendous was the task of numbering nearly 300,000,000 of people under the conditions that obtain in that country. The census of 1901 was the third general census of India and is the most complete yet taken, only a few disturbed tracts in Burma and part of Baluchistan being omitted. Of the total of India, 1,766,597 square miles, 61·5 per cent. is under direct British administration, as is also 78·8 per cent. of the total population, 294,361,056. The Native States comprise over a third of the area with less than one quarter of the population. The largest British province is Burma but by far the most populous is Bengal, which also embraces the most varied physical conditions and the most heterogeneous races. Among the Natives States, Haidarabad, with its 11,000,000 people, stands first. Having started, however, with this brief statement illustrative of the comprehensive character of the work we may say at once that it is not our purpose to deal so much with the statistical portion of it, with its colossal figures and tables, as to pick out here and there some few points which have struck us in going through Part I. of the report as of medical and general interest. These will serve at the same time to afford some indication of the nature and scope of the inquiries instituted and of the great learning and thoroughness with which Mr. Risley, C.I.E., and Mr. Gait, I.C.S., and others have set about and fulfilled their very laborious and absorbing undertaking. The maps, diagrams, and tables are all excellent in their way, clear and pertinent to the subjects in hand. When we think, indeed, of all the labour involved in drawing up these records it is not without a feeling of regret that, despite their intrinsic value and scientific interest, they should not command a wider sphere of consideration and influence than so commonly falls to the lot of official reports to do.

Those who are concerned with the study of demography, ethnology, anthropology, linguistic lore, or the subject of caste will find a large amount of interesting, curious, and instructive material the value of which they cannot fail to appreciate. But for such of our readers as with a limited time at their disposal nevertheless desire to make themselves fairly acquainted with this report we would suggest that they should first of all peruse the introduction and then turn to those chapters in which they are most likely to be interested specially, such as the chapters on sex, infirmities, language, marriage, age, and caste.

The third general census of India dealt with in these volumes was taken on the night of March 1st, 1901, and the system and methods employed in the census operations are detailed by Mr. Gait and Mr. Risley in their introductory remarks. Speaking generally, the census returns show a steady increase of population from 1872 to 1901, but the true rate of progress has been far smaller than would appear from the figures and the reasons for arriving at that conclusion are fully and satisfactorily set forth in the report. Confining ourselves to the period from 1891 to 1901 the true rate of increase of the population is estimated to have been only about 1·5 per cent. There was a gain of 3·9 per cent. in the British provinces but it was accompanied with a decline of 6·6 in the Native States.

With regard to the distribution of the population of India, the most important factor affecting the rural distribution is, as may be easily understood from its connexion with grain and food crops, the water-supply. Tracts of country with heavy and regular rainfall are more densely peopled, while relatively rainless regions have the scantiest population, although this again is modified by such influences as the presence of canals, irrigation, and forests. Taking India as a whole, we find that only one-tenth of the people live in towns. While the growth and population of many old Indian towns and cities are stationary or decadent, Calcutta with its suburbs ranks among the 12 chief cities of the world, and Bombay despite all its troubles is a flourishing and stately city. India, taken as a whole, is not over-populated, for two-thirds of the people live on one-fourth of the area. Burma and Assam have made great progress in the decade, but Bombay and the Central and other Provinces of India have been very gravely affected by famines, plague (which alone probably claimed 1,000,000 victims), and other epidemic diseases.

Chapter III. deals with Sex and we are told that while, with few exceptions, the females outnumber the males in all European countries, in India it is the reverse and in the whole country taken together there are only 963 females to 1000 males. The subject is very exhaustively treated and from various points of view, some of which are pretty well known, while others are relatively new. The chapter abounds with much curious information of various kinds and of more or less interest to the medical statistician and anthropologist.

Chapter IV. treats of Infirmities. It is satisfactory to learn that there has been a decided and continued decline in the number of certain classes of afflicted persons—insane, deaf-mutes, blind and lepers—in the last twenty years. This decline is ascribed to better sanitation and medical relief, improved system of food-supply in times of famine, and largely perhaps in the more careful and exact methods of numbering the people. In Travancore statistics were also collected regarding elephantiasis. There is little insanity in India; Eurasians and Parsees are most affected by it. The mental wear and tear and the strain on the nervous system incidental to the severe competition which obtains in Europe have comparatively no place in the East. The evidence as to the effect of the native consumption of ganja in this respect is somewhat conflicting, but that there is a connexion is no doubt true. As regards social practices the theory that consanguineous marriages have a tendency to produce mental unsoundness receives but little support from the census figures. The influence of race and other conditions in connexion with insanity is discussed and is followed by a consideration of deaf-mutism and leprosy. The latter disease has a very localised prevalence in India. The results of Mr. Jonathan Hutchinson's investigations into the causation of leprosy together with those of the Indian Leprosy Commission and of the Berlin International Conference are passed in review.

Chapter VII. is devoted to "Language" and the subject of Indian languages is handled in expert style. It is headed by a quotation from John Hunter, the father of modern surgery, which is appropriate seeing how many members of the Indian Medical Service have contributed to our knowledge of Indian languages. In the range of philological research there is nothing more provocative of our keen curiosity than the discovery of a tribe or people who speak a language quite unconnected with that of the people surrounding them. At p. 278 of Part I. of the Report will be found a map showing the localities in which the Dravidian and Munda languages of India are spoken. A small isolated patch of colour in Baluchistan, close to Quetta, indicates one islet of the Brahui language, which reminds us that in 1887 Surgeon-Major Theodore Duka, I.M.S., M.R.A.S., a Hungarian by birth, published an excellent and learned essay on the Brāhūi grammar after the German of the late Dr. Trumpp of the University of Munich and in 1874 the late Dr. Bellew, I.M.S., as an appendix to his work "From the Indus to the Tigris" (Trübner and Co.) added a short grammar and vocabulary of the same tongue. It may be useful to those interested in this study to be referred here to vol. v., Part I., of the Linguistic Survey of India, compiled and edited by G. A. Grierson, C.I.E. (Calcutta Government Printing Office, 1903), which deals with the Indo-Aryan family. The survey enumerates altogether 147 languages recorded as vernacular, but as regards their variety and distribution the reader must consult the report. In language, as in other things, India is a land of contrasts—some languages with very rich and others with the most limited vocabularies, some with no past and others with a past of 30 centuries.

---

[1] Census of India, 1901. Two vols. By H. H. Risley, I C.S., C.I.E., Officer of the French Academy, Corresponding Member of the Berlin Anthropological Society, and E. A. Gait, I.C.S., Fellow of the Royal Statistical Society, Anthropological Secretary to the Asiatic Society of Bengal. Calcutta: Office of the Superintendent of Government Printing, India. 1903. Vol. I., 7*s.* 6*d.*, pp. xxv.–582; Vol. IA., 6*s.*, pp. 592.

In attempting to review this voluminous report we have fully realised the meaning of *embarras de richesses*, for we are compelled to pass over those sections dealing with occupation, religion, marriage, age, caste, tribe, and race. In nothing is the contrast so strong between India and Europe as in marriage and the information in the report is instructive and well worth reading. As regards religions we may say that out of the total Indian population in 1901 70 per cent. were Hindus, 21 per cent. were Mahomedans, 3 per cent. were Buddhists, and 1 per cent. were Christians.

EPSOM COLLEGE.

THE annual general meeting of the governors of Epsom College was held at the offices in Soho-square on May 27th, when there was a good attendance, including Dr. C. Holman (treasurer), in the chair, Dr. J. H. Galton, Mr. Stamford Felce, the Rev. E. W. Northey, Dr. J. Roberts Thomson, Mr. George C. Croft, Sir R. Douglas Powell, Dr. G. Eastes, Mr. H. W. Kiallmark, Sir W. S. Church, Dr. M. Baines, Mr. W. A. Propert, and Mr. Reginald Harrison. The secretary having read the notice convening the meeting announced the result of the voting, the successful candidates being as follows:—

PENSIONERS.

	Votes.		Votes.
Sudlow, Rebecca E.	5969	Elliott, Eliza...	4381
Thurgar, Caroline E.	5875		

FOUNDATION SCHOLARS.

Sheperd, Charles L. W. ...	8138	Mortlock, Wm. K.	6327
Walker, Wm. J. G.	7534	Bright, H. Norman	5434
Kenny, Hilary A. H. S. ...	7284	Corry, Eric V.	4536

In moving the adoption of the annual report and the income and expenditure account the treasurer adverted to the loss which the institution had sustained in the death of Sir Edward H. Sieveking, M.D. Edin., a Vice-President, one of the honorary consulting physicians, and for very many years a member of the council. He referred to the services rendered to the institution in its early days by Sir Edward Sieveking, who was the first honorary secretary of the College and whose interest in its work continued until his death. The report showed a surplus of income over expenditure of £2763, but this was entirely owing to the most successful festival dinner which was held last June under the presidency of the Prince of Wales, when the record sum of about £7000 was collected. He announced that he had just received through Mr. Reginald Harrison a munificent donation of £500 from Mr. Thomas Moreton, J.P., honorary local secretary and treasurer for Northwich. In giving this donation Mr. Moreton had made no reserve, thus leaving the Council discretion to use the money as it deemed best. Referring to the change of name effected at the extraordinary general meeting in November the treasurer said that whilst those who were familiar with the work of the College had confidence in the result of that change there was naturally some doubt as to how the general public would receive it. So far as he could judge the change was almost generally welcomed and not only had contributions been coming in freely but this term there was one of the largest entries of new boys on record. He reminded the governors of the progress made by the College in recent years, for whilst there was a debt of £7000 when he accepted the office of treasurer 17 years ago, at the present time the institution was out of debt with the exception of a mortgage of £10,000, but to set against this there were over 80 acres of freehold land apart from the extensive buildings. In conclusion he announced the numbers of the respective classes of boys in the school as follows: 49 foundationers, nine council exhibitioners, 133 other boarders in the College, 34 boarders in masters' houses, and 10 day boys.

The report having been adopted formal business was proceeded with, including the re-election of the auditors and the appointment for a further period of three years of the following members of the council: Dr. Matthew Baines, Dr. Charles Drage, Mr. George P. Field, Sir R. Douglas Powell, Bart., Dr. A. E. Sansom, Mr. Clement L. Smiles, Dr. J. Roberts Thomson, Mr. Hugh E. Vardon, Sir Arthur T. Watson, Bart., K.C., and Colonel Gordon Watson. A vote of thanks to the chairman, proposed by Sir R. Douglas Powell, concluded the proceedings.

ASYLUM REPORTS.

Bristol City and County Asylum, Fishponds (Annual Report for 1903).—The average number of patients resident during the year was 854, comprising 386 males and 468 females. The number of cases admitted during the year amounted to 226—viz., 109 males and 117 females. Of these 194 were first admissions. Dr. Harry A. Benham, the medical superintendent, states in his report that the Bristol board of guardians has determined to provide new buildings for their insane inmates, equipped with all modern improvements, an arrangement which will enable chronic patients of the asylum to be transferred thither from time to time as may be considered expedient. Plans for the scheme of extension of the asylum are in course of preparation and new flushing cisterns have been fixed to lavatories in various parts of the house. A pump has been erected to supply the greenhouses with water and a new ironing machine has been purchased for the laundry. "The whole of the recently acquired land is now under cultivation. We were able to supply 36½ tons of potatoes to the institution during the year." The number of cases discharged as recovered during the year amounted to 109—viz., 53 males and 56 females, or 12·7 per cent. of the average number resident. The deaths during the year amounted to 91, or 10·6 per cent. as calculated on the same basis. Of the deaths two were due to cardiac disease, five to epilepsy, ten to renal disease, 11 to congestion of the lungs, 12 to general paralysis of the insane, 13 to senile decay, 16 to pulmonary and other forms of tuberculosis, and the rest to other causes. Post-mortem examinations were made in 81 cases of death. The Commissioners in Lunacy state in their report that all parts of the asylum continued to be maintained in excellent order, that the wards were tastefully decorated and plentifully supplied with objects of interest, that the dormitories were light and clean, that the patients were in a thoroughly satisfactory condition as regards clothing and personal neatness, and that the medical case-books were well kept. Pathological work is also done by the two assistant medical officers of the institution. There have been no cases of zymotic disease during the year and no inquest has been held. Only one serious casualty occurred in the case of a female patient who accidentally fell and fractured her forearm. The committee of management states in its report that among the patients are included three males and 12 females who are private patients, the rest being chargeable to the county.

East Sussex County Asylum, Haywards Heath (Annual Report for 1903).—The average number of patients resident during the year was 873, comprising 373 males and 500 females. The admissions during the year amounted to 311—

viz., 169 males and 142 females. Of these 230 were first admissions. Dr. E. B. C. Walker, the medical superintendent, states in his report that 86 of the 124 male admissions, excluding transfers and second admissions, and 84 of the 141 female admissions were hopeless as regards prospect of recovery and that 33 males and 38 females were on admission over 55 years of age. The number of patients discharged as recovered during the year amounted to 61—viz., 27 males and 34 females, or 6·9 per cent. of the average number resident. The deaths during the year amounted to 92—viz., 53 males and 39 females, or 13·7 per cent. as calculated on the same basis. Of the deaths three were due to renal disease, four to pulmonary tuberculosis, six to pneumonia, seven each to senile decay and to cardiac disease, nine to epilepsy, 20 to general paralysis of the insane, and the rest to other causes. Four coroner's inquests were held during the year. In two of these death was found to be due to natural causes. The other two were cases of fracture of the hip and leg respectively, accidentally sustained, and verdicts were given in accordance with the evidence, exonerating the asylum officials from blame. The asylum has been free from infectious disease with the exception of one case of scarlet fever. The case was that of a nurse who was found to have the disease on the third day after joining the staff. In November, owing to the accommodation for female patients at the asylum proving inadequate, 15 were transferred to the Lincolnshire County Asylum under contract. This relief to the pressure for room proved to be sufficient until the opening of the new East Sussex County Asylum at Hellingly, which took place in July, when 50 male and 50 female patients were removed there. The Commissioners in Lunacy state in their report that all parts of the asylum were found to be in a satisfactory condition, that the wards were bright and comfortable, that the dormitories and bedding were clean and in good order, and that the medical case-books were carefully and well kept. The committee of management states in its report that in consequence of the removal of a number of patients to East Sussex Asylum at Hellingly the sanatorium, which had been used for some years as an annexe, was on August 1st closed for accommodation of ordinary patients and the temporary buildings were closed a month later, those attendants and nurses who had been engaged for service in the latter receiving notice to leave. The necessary and ordinary repairs of the buildings were carried on, as hitherto, to the end of September.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 7137 births and 4507 deaths were registered during the week ending May 28th. The annual rate of mortality in these towns, which had been 14·9, 16·1, and 15·5 per 1000 in the three preceding weeks, further declined to 15·4 per 1000 last week. In London the death-rate was 14 3 per 1000, while it averaged 15·8 per 1000 in the 75 other large towns. The lowest death-rates in these towns were 3 9 in King's Norton, 5·5 in Devonport, 8·7 in Willesden and in Handsworth (Staffs.), 9·4 in Leyton, 9·6 in Hornsey, and 10·5 in Ipswich; while the highest rates were 19·9 in Bradford, 20·1 in Plymouth, 20·4 in Sunderland and in South Shields, 20·7 in Rochdale, 21·3 in Burnley, 21·7 in Warrington, 22·0 in Bootle, and 22 8 in Hanley. The 4507 deaths in these towns last week included 519 which were referred to the principal infectious diseases, against 514, 525, and 528 in the three preceding weeks; of these 519 deaths 205 resulted from measles, 163 from whooping-cough, 57 from diarrhœa, 41 from diphtheria, 27 from scarlet fever, 22 from "fever" (principally enteric), and four from small-pox. No death from any of these diseases was registered last week in Hastings, Reading, Ipswich, Burton-on-Trent, Handsworth (Staffs.), King's Norton, Smethwick, Grimsby, Preston, Stockton-on-Tees, or Tynemouth; while the highest death-rates from the principal infectious diseases were recorded in Aston Manor, Coventry, Birkenhead, Wallasey, Salford, Blackburn, Rotherham, and Rhondda. The greatest proportional mortality from measles occurred in Croydon, Walthamstow, Brighton, Birkenhead, Wallasey, Burnley, Middlesbrough, Leeds, and Rotherham; from whooping-cough in Plymouth, Walsall, Aston Manor, Coventry, Birkenhead, Bootle, Bolton, Blackburn, and Merthyr Tydfil; and from diarrhœa in Hanley and West Bromwich. The mortality from scarlet fever, from diphtheria, and from "fever" showed no marked excess in any of the large towns. Of the four fatal cases of small-pox registered in these towns last week two belonged to London, one to Stockport, and one to Bradford. The number of small-pox cases under treatment in the Metropolitan Asylums hospitals, which had been 88, 99, and 96 at the end of the three preceding weeks, had risen again to 118 at the end of last week; 33 new cases were admitted during the week, against 14, 26, and 18 in the three preceding weeks. The number of scarlet fever patients in these hospitals and in the London Fever Hospital on Saturday last, May 28th, was 1663, against 1590, 1600, and 1630, on the three preceding Saturdays; 194 new cases were admitted during the week, against 242, 239, and 222 in the three preceding weeks. The deaths in London referred to pneumonia and diseases of the respiratory system, which had been 193, 231, and 210 in the three preceding weeks, further declined last week to 188 but were slightly in excess of the number in the corresponding period of last year. The causes of 52, or 1·2 per cent., of the deaths in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Bristol, Nottingham, Leeds, and in 46 other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, St. Helen's, Manchester, Blackburn, Preston, and South Shields.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 18·0, 17·9, and 18·7 per 1000 in the three preceding weeks, declined again to 17·6 per 1000 during the week ending May 28th, but was 2·2 per 1000 in excess of the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 14·9 in Paisley and 15·3 in Aberdeen, to 20·0 in Edinburgh and 21·5 in Perth. The 582 deaths in these towns included 29 which were referred to whooping-cough, 15 to diarrhœa, 12 to measles, three to diphtheria, two to scarlet fever, and one to small-pox, but not any to "fever." In all, 62 deaths resulted from these principal infectious diseases last week, against 64, 75, and 58 in the three preceding weeks. These 62 deaths were equal to an annual rate of 1·9 per 1000, which was slightly in excess of the mean rate last week from the same diseases in the 76 large English towns. The fatal cases of whooping-cough, which had been 25, 28, and 21 in the three preceding weeks, rose again last week to 29, of which nine occurs in Glasgow, nine in Dundee, five in Edinburgh, and four in Aberdeen. The deaths from diarrhœa, which had been 15 and 13 in the two preceding weeks, rose again to 15 last week, and included five in Glasgow, five in Edinburgh, three in Dundee, and two in Aberdeen. The fatal cases of measles, which had been 17 and 16 in the two preceding weeks, further declined last week to 12, of which three were registered in Dundee, three in Paisley, two in Glasgow, two in Edinburgh, and two in Greenock. Of the three deaths from diphtheria two belonged to Glasgow, where the fatal case of small-pox also were registered. The deaths referred to diseases of the respiratory organs in these towns, which had been 100, 90, and 97 in the three preceding weeks, declined again last week to 85, and were 29 below the number in the corresponding period of last year. The causes of 20, or nearly 3 per cent., of the deaths registered in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 23·1, 21·6, and 21·9 per 1000 in the three preceding weeks, declined again to 21·3 per 1000 during the week ending May 28th. During the past four weeks the death-rate has averaged 22·0 per 1000, the rates during the same period being 15·2 in London and 17·6 in Edinburgh. The 155 deaths of persons belonging to Dublin registered during the week under notice showed a decline of four from the number in the preceding week and included eight which were referred to the principal infectious diseases, against 18, 17, and 13 in the three preceding weeks; of these, four resulted from whooping-cough, two from scarlet fever, one from "fever," and one from diarrhœa, but not any from small-pox, measles, or diphtheria. These eight deaths were equal to an annual rate of 1·1 per 1000, the death-rates last week from the principal infectious diseases being 1·7 in London and 2·2 in Edinburgh. The fatal cases of whooping-cough, which had been 11, ten, and five in the three preceding weeks, further declined last week to four. Two deaths from scarlet fever were recorded, against one in each of the two preceding weeks. The 165 deaths in Dublin last week included 26 of children under one year of age and 31 of persons aged 60 years and upwards; the deaths of infants exceeded the number in the preceding week, while those of elderly persons showed a considerable decline. Two inquest cases and two deaths from violence were registered, and 62, or two-fifths, of the deaths occurred in public institutions. The causes of 12, or nearly 8 per cent., of the deaths in Dublin last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following qualified candidates for the Naval Medical Service have been appointed Surgeons in His Majesty's Fleet:—Harry Arthur Kellond-Knight, Hugh Bernard German, Douglas Duke Turner, Alfred Berridge Cox, Gordon Moir, Briton Smallman Robson, Alfred Austin Chancellor, Norman Bremer Vickers Jacob, Herbert Stone, Gerald Nunn, Bryan Pick, William Lawrence Hawkins, John Herbert McDowall, George Eric Hamilton, John Duncan Keir, George Oswald Morrell Dickenson, Alex Bedingfeld Marsh, James McCutcheon, John Miller Gordon, William Christian Baumgarten Smith, Thomas Edward Blunt, Leslie Charles Robinson, Francis Edwin McCune, Frank Reginald Featherstone, and Walter Turner Haydon (dated May 23rd, 1904).

The undermentioned gentleman has been appointed Surgeon in His Majesty's Fleet:—William Nichols Horsfall (dated May 23rd, 1904).

ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel J. Carmichael has joined at Warley for duty. Captain O. Challis is posted to the Station Hospital, Colchester, for duty. Captain W. R. P. Goodwin is selected to officiate as Personal Assistant to the Principal Medical Officer, Punjab Command.

THE ROYAL MILITARY TOURNAMENT.

A better exhibition of military smartness, nerve, and muscle than that presented at the Royal Military Tournament has never previously been seen at the Agricultural Hall. Compared with other years there is less spectacular effect, but from a purely physical point of view it would be difficult to improve on the present tournament. The first item of the programme which attracts attention is the splendid display by the staff of the headquarters gymnasium at Aldershot who illustrate a method of gymnastic training that not only develops the muscles but quickens the intellect in a remarkable degree. In previous years we have described similar exercises performed by non-commissioned officers under training and by recruits from the marine depôt at Deal and now we have an opportunity of witnessing the performances of the instructors themselves. To those who look beneath the surface of things it is perhaps the finest part of the tournament. Then there is the 12 pounder gun drill by the seamen of H.M.S. *Excellent* and the manner in which the guns are dismounted and remounted, manœuvred, and lifted over a four-foot wall shows clearly that the ability and resource said to be possessed by the men of our navy is no fiction but an absolute fact. The display by the Royal Marine Artillery is another item illustrating the smartness and resource of our "soldier sailors." A five-inch B.L. gun weighing two tons is placed with its mounting as used on board ship and weighing 42 hundredweights, together with the necessary stores on a wagon (total weight six tons), and drawn into the arena. The gun is then mounted by means of an extemporised gin, brought into action, fired, after which the gin is "struck," dismounted, and replaced in the wagon. The display by the Army Service Corps, too, will be watched with interest. The usual displays of riding, jumping, tent-pegging, combats between various arms, the musical drive by the Royal Artillery, the Royal Horse Artillery galloping, Royal Field Artillery trotting, and other items common to the tournament are carried out in a manner which does credit to all concerned. The musical drive of the 1st Life Guards is a fine performance of its kind and always receives the applause it undoubtedly deserves. On the latter days of the tournament this drive will be performed by the 21st Lancers. The pageant representing the rise of the Royal Artillery is an object lesson in British history, introducing the bombard and matchlock of the Middle Ages and various engines of war from Crecy to the Boer war with its 12 pounders and "pom-poms." Pushball as played by a team of the Royal Horse Guards is a performance at once clever and amusing, the horses entering into the spirit of the game, and this quality of the horse is exhibited in a still more remarkable degree in the contest between four mounted men from the riding establishment at Canterbury and four horses with dummy riders. The object of the mounted men is to strike with their swords from the helmets of the dummies paper plumes. The clever manner in which the horses with their dummy riders escape from the mounted men must be seen to be appreciated, while the ludicrous way in which the dummies jerk their limbs about in consequence of the motion of the horses keeps the spectators in a constant roar of laughter. The resources of the executive committee in providing fresh features for the annual tournament seem to be unlimited, but it will be difficult for it to equal the entertainment which it has provided for the public this year.

The sanitary arrangements are as good as the medical officers in charge of the tournament can make them, considering the limited space which a building like the Agricultural Hall, never intended for military shows on such a large scale, allows, and the same thing applies to the comfort of the spectators. It is, however, unfortunate that a larger and more suitable home cannot be found for an entertainment which, in addition to its principal objects of encouraging and developing skill at arms and of benefiting military charities, must of necessity educate the public in naval and military matters and act as an important aid to recruiting. While congratulating the executive committee and the staff generally upon the success of the present tournament we would ask them to consider whether it would not be possible to make its scope still wider and to enlarge its sphere of usefulness by transferring it to a building more suited to large military displays and where the public would have a better opportunity of seeing a bird's eye view of the two services with their auxiliaries which have helped to build our great Empire. The tournament will close on June 9th.

H.H. PRINCE ALEXANDER OF BATTENBERG.

Midshipman H.H. Prince Alexander of Battenberg, who is serving in the *Cæsar*, flagship of Vice-Admiral Lord Charles Beresford, has been seriously ill on board the hospital ship *Maine*, suffering from pneumonia, but is now reported convalescent.

THE WAR IN THE FAR EAST.

That a series of successes on the part of the Mikado's land forces have followed on the great initial one obtained by the Japanese fleet has now become patent to everyone. The two big defeats of the Russians on the Yalu and at Kin-Chau with the capture of 78 Russian guns at the latter battle have been followed by the occupation of Dalny—the great Russian mercantile port and harbour—by General Oku's troops, and a renewed attempt has been made by Admiral Togo to complete the "bottling up" of Port Arthur on the side of the sea. Nor is this all. What happened in the Franco-German war and in the late Boer war in the case of the "entanglement" of Ladysmith seems likely to be repeated in the case of Port Arthur which begins its siege with the return of the defeated troops from Kin-Chau bringing with them their wounded to occupy its military hospitals. Assuming that 500 dead Russian soldiers were found by the Japanese after Kin-Chau and that the proportion be taken as four wounded to one killed we may estimate the Russian losses at 2000 at least on that occasion Kuropatkin with his force at Mukden is in the meantime placed in a most difficult position owing to his very natural desire not to abandon Port Arthur and to leave its garrison to its fate. With Japanese forces to his rear and in his vicinity ready to cut his troops off from their base the situation is obviously one of perplexing jeopardy. The revelation of so much preparedness, strategic skill, daring, and discipline on the part of the Japanese, their minute attention to details, and the splendid coöperation of their army and navy in the work before them have probably caused more astonishment on the continent than in this country. And yet the Japanese troops who took part as a contingent in the operations in China some four years ago made a very powerful impression on General Frey who was then in command of the French troops. The General wrote of the Japanese contingent on that occasion in terms of surprise and the highest admiration. From all we can learn from our own naval and military medical officers who have had personal experience and intercourse with the Japanese they were greatly impressed with their care, skill, and thoroughness in all they undertook. So much, as everyone knows, turns in war on commissariat and transport, and in the case of the Russians a good deal of the sickness among the troops in Manchuria is alleged to be attributable to the character of the clothing, supplies, and foodstuffs furnished by dishonest contractors. The Japanese medical officers are reported to have shown every attention and consideration to the Russian wounded and prisoners that fell into their hands and the Russian medical officers worked in the same spirit among the Japanese sick and wounded. Among the items of news we learn from Peking that an Imperial Order has been issued for the establishment of a Chinese Red Cross Society under the terms of the Geneva Convention.

Some days ago, says the *Novoe Vremya*, two complete portable mechanical medical disinfecting rooms, made by a Warsaw house, were despatched to the Far East. The whole combination is included in two third-class carriages. In the first there is a plant to treat 30 poods of dry linen (the pood being 36 pounds) consisting of a machine for washing, rinsing, and wringing linen, a steam mangle, and water boiler, &c. In the second carriage there are two disinfecting chambers, one acting with dry steam and the other with formalin. A portable artificial ice-producing machine in a goods wagon is also in course of preparation to make 100 poods of ice a day.

The Odessa branch of the Society for the Preservation of the Public Health has opened subscriptions for the families of medical men killed or wounded in the war and of medical men ordered to the front who require assistance. There has been a generous response to the appeal.

The *Novosti* describes a hospital train consisting of nine goods wagons and two Pullman passenger cars just despatched to the Far East which was fitted up at the expense of the Russian "South-Western Railway" employés. The cost was £3500. The staff attached to this train consists of five physicians, a pharmacist, four field medical officers, 14 sanitary officers, eight servants, three cooks, 14 sisters of mercy, and a steward. The train is abundantly furnished with medicines, linen, and surgical instruments.

The Tsaritsa's hospital train, which is described as the finest railway hospital ever constructed, has left St. Petersburg for the East.

Correspondence.

"Audi alteram partem."

THE INFANT ORPHAN ASYLUM AT WANSTEAD.

To the Editors of THE LANCET.

SIRS,—The Infant Orphan Asylum at Wanstead is a charitable institution, supported by the public, containing over 500 children of both sexes, all of whom are of an age when they are particularly liable to infectious diseases and, even more than adults, require skilled nursing when attacked by illness.

The committee has lately, by refusing to make arrangements for the proper isolation of infectious cases and still more by dismissing its staff of trained nurses, taken so retrograde a step that we think it our duty to call the attention of the public thereto. We ask you, therefore, to find space for the following letter conveying the resignation of our respective positions as consulting physician and consulting surgeon to the asylum.

We are, Sirs, yours faithfully,
W. P. HERRINGHAM.
May 30th, 1904. ANTHONY A. BOWLBY.

[INCLOSURE.]

May 3rd, 1904.

To the Chairman of the Infant Orphan Asylum.

DEAR SIR,—Three years ago your committee requested one of your consulting medical staff to report upon the arrangements for the care of cases of sickness occurring at the asylum. The report advised (1) that certain alterations should be made in the existing infirmary; (2) that adequate provision should be made for the isolation of infectious cases and for the disinfection of clothes and bedding by building an isolation block and by purchasing a steam disinfector; and (3) that the infirmary and isolation block should be under the charge of a trained nurse of the status of a hospital sister with at least one trained nurse under her orders.

That report was approved by your committee at the time. Within the last month your committee has decided: (1) "That an isolation block will not be provided." (2) "That trained nurses will be abolished as permanent staff and the infirmary will be under the charge of an untrained head nurse." (3) "That the mild cases now composing and termed out-patients will be treated by their own nurses in the main building."

All these decisions have been arrived at without asking the opinion of any of your medical staff. We have informed you that we consider that these arrangements do not make adequate provision for the health and treatment of the children. These number now more than 500, many of them are babies, and all are of an age at which they are specially prone to many infectious disorders. We consider that so long as our names appear as members of your consulting staff we may be held responsible for these arrangements. We have asked for an opportunity to meet your committee in company with your local medical officer that we may state our opinions and discuss the questions that have arisen. Our request has not been granted and we have therefore no alternative but to tender you our resignation. We reserve to ourselves the right to publish this letter.

We remain, yours faithfully,
W. P. HERRINGHAM, M.D., F.R.C.P.
ANTHONY A. BOWLBY, C.M.G., F.R.C.S.

*** Mr. A. E. Cumberbatch and Mr. W. T. Holmes Spicer, who were consulting aural surgeon and consulting ophthalmic surgeon respectively to the Infant Orphan Asylum, have, we learn, also both resigned.—ED. L.

THE METROPOLITAN STREET AMBULANCE ASSOCIATION.

To the Editors of THE LANCET.

SIRS,—The rapid growth of this association and the necessity of supplying the demand for information on the ambulance question has led to a greater expenditure on postage, printing, and incidental expenses than was anticipated. It has been decided therefore that a fund of about £70 to £80 should be formed from voluntary donations to meet present and future needs. Donations may be sent to Mr. A. A. Bowlby, 24, Manchester-square, London, W., or to me.

I am, Sirs, yours faithfully,
ARTHUR JAMES, Hon. Secretary.
69, Gloucester terrace, Hyde Park, London, W., May 28th, 1904.

The following donations have been received :—

	£	s.	d.		£	s.	d.
Mr. Reginald Harrison, President...	2	2	0	Dr. H. D. Rolleston ...	1	1	0
Mr. James Berry	1	1	0	Mr. Cuthbert S. Wallace	1	1	0

NEURO-RETINITIS IN CHLOROSIS: A CORRECTION.

To the Editors of THE LANCET.

SIRS,—I regret that in my paper on the above subject[1] I should have inadvertently attributed to Dr. C. O. Hawthorne the suggestion that the primary cause of the optic neuritis was thrombosis of the cavernous sinus whilst it should have read "thrombosis of one or more of the intracranial sinuses or veins."

I am obliged to Dr. Hawthorne for directing my attention to the mistake and also for the lucid explanation of his view, the detailed discussion of which, and of other theories, was beyond the scope of my paper.

I am, Sirs, yours faithfully,
Birmingham, May 31st, 1904. J. JAMESON EVANS.

THE PRESENT STATE OF MEDICAL PRACTICE IN SOUTH AFRICA: A WARNING.

To the Editors of THE LANCET.

SIRS,—I think a few words on the subject of medical practice in South Africa may perhaps prove useful to those of the profession at home who contemplate coming to this part of the world to engage in practice. Prior to the South

---

[1] THE LANCET, May 14th, 1904, p. 1345.

African war there were many openings both in town and country districts where the average medical man could have made certain of working up a good practice. More especially did this apply to up-country districts in Cape Colony and Natal. Over and over again it has been remarked to me by medical men and laymen alike, "If you go to such and such a place you will be fairly certain to capture the present man's practice, he drinks so heavily," and no doubt many practices have been lost and obtained in this way. It is a sad thing to admit, but many medical men in up-country districts are addicted to alcohol and the morphia habit—chiefly unmarried men I believe. The monotony and loneliness of the life are responsible for this apparently. But I am straying from the point. During the war hundreds of civil surgeons came out from England and at its conclusion a very considerable percentage stayed out here. They obtained all the Government billets in the new colonies—e.g., the district surgeoncies—and with such appointments as nuclei they settled in various parts of the country and many are doing well. The result is that small towns and districts which formerly supported one medical man now have their three or even four. Similarly at the close of the war many new men settled in the large coast towns and in these the profession is certainly overcrowded; there must be many who are hard put to it to make a decent living. A friend of mine who is a well-known practitioner in a large town has calculated that in proportion to population there are more medical men out here than at home and I quite believe it. Of course, in the country, owing to its large extent and scattered population, this must needs be, but in the towns the conditions are the same as at home.

Medical men, unless possessed of considerable means, who contemplate emigration to South Africa, should think well on the matter. I would also point out here the great cost of living. House rent is exorbitant in the large towns and as all the colonies are protectionist the prices are naturally enhanced all round. Fees are higher than at home, of course, ranging from 5s. to 7s. in towns and according to distance in the country, but these do not compensate for the increased cost of living. To the general practitioner, then, the cry is "full up" at present. There may perhaps be room in the large towns for men who have specialised in diseases of the eye, skin, nose, throat, and ear, especially the former two. Finally, a word of warning may not be out of place to those desirous of buying practices in South Africa. A great deal of caution is needed to avoid being "let in" for a practice which is rapidly diminishing; this refers chiefly to up-country practices. Medical men, in common with every other class, are feeling the pinch of the present depression, but when this passes away and the country begins to expand and immigration to take place on a large scale then, no doubt, there will not only be plenty of room for the men already in practice here but for many more who are desirous of coming. My object in writing these lines will have been attained if they afford food for reflection to those at home who may be looking upon South Africa as an El Dorado (from a medical point of view) in its present state. Apologising for the length of this communication,

I am, Sirs, yours faithfully,

Maritzburg, Natal, May 6th, 1904. H. J. W.

A VISIT TO LYONS.

(FROM A CORRESPONDENT.)

LYONS has five general hospitals, with an aggregate of 6000 beds, and it is unnecessary to say that its medical school has a world-wide reputation. The professors themselves consider that one of their great advantages is that every section of the hospitals has its own laboratory, so that the professor in charge can do any research work in which he and his assistants are interested without being at the mercy or the good nature of a colleague who may easily be less interested in their particular line of investigation. A statue is being erected to Dr. Ollier, a noted surgeon of the town, who was the first to point out the need of preserving the periosteum in resections of bones and excisions of joints. There are still living some of his old operation cases dating from the war of 1870.

The students are engaged in hospital work during their second, third, and fourth years, and besides passing five examinations they still have to write a thesis. The total fees of their medical course only amount to £56, which is enough to make the parents of London students envious. Each student who passes successfully becomes a doctor of medicine and there is some talk of instituting a higher title such as "doctor of medical science" for those who wish to pass an honours examination and to qualify themselves for teaching posts. The old title of "officier de santé," which was a much lower qualification, now no longer exists. There are in Lyons 1500 medical students, including 45 ladies all of whom are Russian Nihilists except three or four French women. The Russian ladies are always poor, subsisting on bread and tea, and living two or three in one room After being qualified they are employed by the Russian Government as country practitioners. The French lady doctors occasionally make successful practices in Paris but not in the provinces. At the last examination for 40 "internes" a lady student (a French Protestant) was elected at their head. This examination takes place once a year, when about 150 of the best students compete in their third year to become "internes." The successful competitors are kept by the State for four years and the best of them eventually become assistants of various kinds and later professors. For some unknown reason the French women refuse to become druggists. An interesting relic of old times exists in the diploma which is still given to herbalists who are mostly women. Candidates must bring a certificate of being 21 years of age and of good moral character, after which they are examined in their knowledge of medical plants, which includes the gathering, drying, and preparation of the plants. Although Lyons is the leading commercial city of France it has had almost exclusively for a hundred years a medical man as mayor. Each mayor is appointed for six years, so he has time to introduce hygienic reforms.

The Hôtel Dieu with 1200 beds is the oldest and chief hospital, dating from the eighth century, and is now about to be demolished and turned into public museums and libraries. The patients will be transferred to two new hospitals which are to be built outside the town. The large wards are now crammed with patients in four rows of beds, so that only half the sick can ever be near the windows. The windows were mostly shut at my visits, the air seemed stagnant, and it was a relief to get into the corridors and staircases outside the wards. The patients looked anæmic, but this was perhaps due to the great number of tuberculous cases, for there is as yet no hospital for consumption in Lyons. This question has already been before the university, for it is stated that phthisis is on the increase in France. The hospital corridors and many public places were furnished with spittoons attached to the walls, with plentiful notices to prevent all spitting on the floors. In the operating theatres the surgeons have made most gallant efforts to prevent septicism, but the wards are so irretrievably bad that but little can be done there. The whole hospital is nursed by old-fashioned *sœurs de charité* in stuff dresses, devoted pious women quite certain to go to heaven themselves but not always calculated to prevent their patients going there prematurely! Professor Gayet showed me a splendid collection for a future album of enlarged photographs of sections of eyes, and I noticed in his ophthalmic wards that all the windows were draped with dark blue curtains which were only drawn back when it was necessary to examine the eyes.

The medico-legal museum is a unique and valuable collection of photographs, weapons, stabbed organs, fractured skulls, poisons, and models of all kinds. There is the dagger which the Italian assassin thrust into the liver of President Carnot in one of the principal streets of the town, and a piece of string which after being passed into a male urethra was found spontaneously knotted in the bladder. Dr. Lortet, professor of parasitology, kindly allowed me to see his splendid collection of parasites, mostly shown by lantern slides and photographs, demonstrating their effects on the human body. The photograph rooms of the medical side of the university are very well fitted up. Professor Arloing conducted me over the veterinary department where there were five horses in use for preparing antidiphtheritic and antitetanus serums. The energetic Dr. J. Courmont is professor of hygiene, physician of one of the hospitals, and also sanitary inspector of the town. His hygienic laboratory is the newest and most complete in France, with centrifugalisers and other instruments worked by electricity, and a museum of sanitary appliances. Among the students walking about were many in uniform who belong to that portion of the caused more astonishment on the continent than in this country. And yet the Japanese troops who took part as a contingent in the operations in China some four years ago made a very powerful impression on General Frey who was then in command of the French troops. The General wrote of the Japanese contingent on that occasion in terms of surprise and the highest admiration. From all we can learn from our own naval and military medical officers who have had personal experience and intercourse with the Japanese they were greatly impressed with their care, skill, and thoroughness in all they undertook. So much, as everyone knows, turns in war on commissariat and transport, and in the case of the Russians a good deal of the sickness among the troops in Manchuria is alleged to be attributable to the character of the clothing, supplies, and foodstuffs furnished by dishonest contractors. The Japanese medical officers are reported to have shown every attention and consideration to the Russian wounded and prisoners that fell into their hands and the Russian medical officers worked in the same spirit among the Japanese sick and wounded. Among the items of news we learn from Peking that an Imperial Order has been issued for the establishment of a Chinese Red Cross Society under the terms of the Geneva Convention.

Some days ago, says the *Novoe Vremya*, two complete portable mechanical medical disinfecting rooms, made by a Warsaw house, were despatched to the Far East. The whole combination is included in two third-class carriages. In the first there is a plant to treat 30 poods of dry linen (the pood being 36 pounds) consisting of a machine for washing, rinsing, and wringing linen, a steam mangle, and water boiler, &c. In the second carriage there are two disinfecting chambers, one acting with dry steam and the other with formalin. A portable artificial ice-producing machine in a goods wagon is also in course of preparation to make 100 poods of ice a day.

The Odessa branch of the Society for the Preservation of the Public Health has opened subscriptions for the families of medical men killed or wounded in the war and of medical men ordered to the front who require assistance. There has been a generous response to the appeal.

The *Novosti* describes a hospital train consisting of nine goods wagons and two Pullman passenger cars just despatched to the Far East which was fitted up at the expense of the Russian "South-Western Railway" employés. The cost was £3500. The staff attached to this train consists of five physicians, a pharmacist, four field medical officers, 14 sanitary officers, eight servants, three cooks, 14 sisters of mercy, and a steward. The train is abundantly furnished with medicines, linen, and surgical instruments.

The Tsaritsa's hospital train, which is described as the finest railway hospital ever constructed, has left St. Petersburg for the East.

"Audi alteram partem."

THE INFANT ORPHAN ASYLUM AT WANSTEAD.

To the Editors of THE LANCET.

SIRS,—The Infant Orphan Asylum at Wanstead is a charitable institution, supported by the public, containing over 500 children of both sexes, all of whom are of an age when they are particularly liable to infectious diseases and, even more than adults, require skilled nursing when attacked by illness.

The committee has lately, by refusing to make arrangements for the proper isolation of infectious cases and still more by dismissing its staff of trained nurses, taken so retrograde a step that we think it our duty to call the attention of the public thereto. We ask you, therefore, to find space for the following letter conveying the resignation of our respective positions as consulting physician and consulting surgeon to the asylum.

We are, Sirs, yours faithfully,
W. P. HERRINGHAM.
May 30th, 1904. ANTHONY A. BOWLBY.

[INCLOSURE.]

May 3rd, 1904.

To the Chairman of the Infant Orphan Asylum.

DEAR SIR,—Three years ago your committee requested one of your consulting medical staff to report upon the arrangements for the care of cases of sickness occurring at the asylum. The report advised (1) that certain alterations should be made in the existing infirmary; (2) that adequate provision should be made for the isolation of infectious cases and for the disinfection of clothes and bedding by building an isolation block and by purchasing a steam disinfector; and (3) that the infirmary and isolation block should be under the charge of a trained nurse of the status of a hospital sister with at least one trained nurse under her orders.

That report was approved by your committee at the time. Within the last m[illegible] will not b[illegible] manent sta[illegible] head nurse." (3) "That the mild cases now composing and termed out-patients will be treated by their own nurses in the main building."

All these decisions have been arrived at without asking the opinion of any of your medical staff. We have informed you that we consider that these arrangements do not make adequate provision for the health and treatment of the children. These number now more than 500, many of them are babies, and all a[illegible] they are specially prone to many infectious [illegible] that so long as our names appear as members [illegible] we may be held responsible for these arrangements. We have asked for an opportunity to meet your committee in company with your local medical officer that we may state our opinions and discuss the questions that have arisen. Our request has not been granted and we have therefore no alternative but to tender you our resignation. We reserve to ourselves the right to publish this letter.

We remain, yours faithfully,
W. P. HERRINGHAM, M.D., F.R.C.P.
ANTHONY A. BOWLBY, C.M.G., F.R.C.S.

*** Mr. A. E. Cumberbatch and Mr. W. T. Holmes Spicer, who were consulting aural surgeon and consulting ophthalmic surgeon respectively to the Infant Orphan Asylum, have, we learn, also both resigned.—ED. L.

THE METROPOLITAN STREET AMBULANCE ASSOCIATION.

To the Editors of THE LANCET.

SIRS,—The rapid growth of this association and the necessity of supplying the demand for information on the ambulance question has led to a greater expenditure on postage, printing, and incidental expenses than was anticipated. It has been decided therefore that a fund of about £70 to £80 should be formed from voluntary donations to meet present and future needs. Donations may be sent to Mr. A. A. Bowlby, 24, Manchester-square, London, W., or to me.

I am, Sirs, yours faithfully,
ARTHUR JAMES, Hon. Secretary.
69, Gloucester-terrace, Hyde Park, London, W., May 28th, 1904.

The following donations have been received :—

	£	s.	d.
Mr. Reginald Harrison, President...	2	2	0
Mr. James Berry	1	1	0
Mr. A. A. Bowlby	2	2	0
Dr. R. J. Collie	1	1	0

NEURO-RETINITIS IN CHLOROSIS: A CORRECTION.

To the Editors of THE LANCET.

SIRS,—I regret that in my paper on the above subject[1] I should have inadvertently attributed to Dr. C. O. Hawthorne the suggestion that the primary cause of the optic neuritis was thrombosis of the cavernous sinus whilst it should have read "thrombosis of one or more of the intracranial sinuses or veins."

I am obliged to Dr. Hawthorne for directing my attention to the mistake and also for the lucid explanation of his view, the detailed discussion of which, and of other theories, was beyond the scope of my paper.

I am, Sirs, yours faithfully,
J. JAMESON EVANS.
Birmingham, May 31st, 1904.

THE PRESENT STATE OF MEDICAL PRACTICE IN SOUTH AFRICA: A WARNING.

To the Editors of THE LANCET.

SIRS,—I think a few words on the subject of medical practice in South Africa may perhaps prove useful to those of the profession at home who contemplate coming to this part of the world to engage in practice. Prior to the South which surra disease had been communicated by inoculation. The Pettenkofer apparatus was used and the production of heat was measured by indirect calorimetry. The production of heat rose one day 45·6 per cent. and was greater than could be accounted for by the toxogenic disintegration of albumin. Dr. Staehelin came to the conclusion that in fever an increased metabolism of albumin was not the only process involved, as was proved by the decomposition of glycogen and the excretion of acetone.

---

[1] THE LANCET, May 14th, 1904, p. 1345.

Dr. MOHR (Berlin) said that in fever the excretion of carbon in the urine was not increased relatively to the excretion of nitrogen, a fact which showed that there was no considerable alteration of the metabolism.

Diet in Cholelithiasis.

Dr. CLEMM (Darmstadt) said that a sufficient flow of bile was the best means of counteracting inflammations of the bile passages. This result was most easily obtained by the use of a mixed diet containing plenty of lean meat and also of fatty substances (Fett- und Fleischnahrung); the cholagogic action of lean meat was powerful but of short duration, whilst that of fatty substances was more prolonged. The fat of milk in the form either of fresh or sour cream or of butter, the fat of the yelk of egg, salad oil, and raw smoked bacon were the best. The fat which was separated from meat on boiling or roasting was less emulsifiable than it otherwise would be.

Speech Defects in Neurasthenic Persons.

Dr. GUTZMANN (Berlin) spoke on impairment of coördination as affecting the organs of speech and especially on stuttering. Up to the present time stuttering had not been regarded as an effect of neurasthenia, but Dr. Gutzmann had found that a good many stutterers in the course of time developed unquestionable neurasthenic symptoms. On the other hand, neurasthenic patients might become stutterers. Treatment must be directed both to the patient's general state and also to the local conditions.

The Motor Function of the Vagus Nerve.

Professor STARCK (Heidelberg) gave a report of experiments made by him on the function of the vagus. He tried to produce dilatation of the œsophagus in dogs by resection of the vagus within the thoracic cavity above and below the hilum of the lung and above the cardia. Resection of the vagus did not produce contraction of the cardia; dilatation of the œsophagus might, however, be rendered possible by paresis of the muscles of the œsophagus. Atrophy of the vagus could only be accepted as a cause of dilatation of the œsophagus in the event of no hypertrophy of the muscles being found post mortem, as paralysed muscle could not become hypertrophied. Resection of the vagus below the hilum did not cause dilatation, because the motor fibres entered at a point higher up the œsophagus.

"Photodynamic" Action of Some Fluorescent Substances.

Professor VON TAPPEINER (Munich) said that certain fluorescent substances which in darkness were scarcely toxic acquired in sunlight or diffuse daylight the power of destroying infusoria and cells and of neutralising toxins and enzymes. Even weak solutions of the substances in question exhibited this photodynamic action. He had examined eosin, chinolin-red, harmalin, acridin, and fluorescin, and found that their photodynamic action was in inverse ratio to the degree of fluorescence. By the action of the above substances ricin, for instance, lost not only its general toxic quality but also its power to agglutinate erythrocytes, diphtheria toxin was rendered absolutely inert, and tetanus toxin was considerably weakened. By experiments on animals inoculated with diphtheria toxin it was found that the fluorescent compounds had also a certain therapeutic effect. Injections of eosin had a beneficial effect in rodent ulcer, lupus, and chancre. Although the photodynamic action increased as the fluorescence diminished, it nevertheless came to an end completely when the fluorescence disappeared.

Dr. SEIFERT (Würzburg) confirmed the above statements as to the therapeutic results obtained by eosin in lupus and mycosis.

The Action of Digitalis.

Dr. BRANDENBURG (Berlin) said that digitalis rendered the heart muscle more resistant to external irritants, such as the electric current. On the other hand, it imparted the power of motility to portions of the heart where movements could not else occur. This effect took place even when nervous influence was excluded.

The Virulence of Pneumococci.

Dr. STUERTZ (Berlin) said that he had found by numerous researches that the virulence of pneumococci present in pneumonia was proportionate to the severity of the disease, and he therefore concluded that the prognosis might be arrived at by bacteriological examination of the sputum. The virulence decreased only 24 hours after the crisis.

Diabetic Coma.

Professor KRAUSE (Breslau) said that he had found in three cases of diabetic coma a marked decrease of tension on palpation of the eyes. A comparable decrease of tension was not observed in persons kept without water, or in the dying, or even in the dead. An anatomical explanation of the decrease of tension was not forthcoming and Professor Krause tried to produce this symptom artificially by the injection of excreted products which were characteristic for diabetic coma, such as acetone and beta-oxybutyric acid. The symptom was not present in phloridzin diabetes and pancreatic diabetes. It was also absent in other forms of coma such as that of Addison's disease. The symptom appeared only a short time previously to death.

Polycythæmia.

Dr. GRESBOECK (Munich) described an ailment which was characterised by marked polycythæmia. In some cases the blood counts showed that there were from 6,000,000 to 11,000,000 red corpuscles per cubic millimetre. The amount of hæmoglobin was from 140 to 150 per cent. and was equal in venous and arterial blood. The blood pressure was found to be abnormally high. The most striking external symptom was the intense red colour of the skin on the face, the extremities, the mucous membranes, and the retina. The causes of the disease were unknown. The patients observed by Dr. Gresboeck were not engaged in exceptionally laborious or exhausting occupations.

Antistreptococcic Treatment.

Dr. MENZER (Halle) reported a series of cases of rheumatic polyarthritis which were cured by his antistreptococcic serum. According to him rheumatic endocarditis and chorea were also amenable to his method.

Dr. ARONSON (Berlin) said that the fever observed after injections of Dr. Menzer's serum was not of antitoxic but of toxic origin. On the injection of toxin-free serum the temperature ought to become normal at once.

Professor WOLFF (Berlin) said that the fever following Dr. Menzer's injections was the consequence of endotoxins precipitated by the bactericidal serum.

Dr. MICHAELIS (Berlin) said that injections of the same serum could not cure polyarthritis and mixed infections by tubercle bacilli and streptococci. The streptococcus of rheumatic polyarthritis and the streptococcus present in tuberculous cavities of the lungs were two quite different species which were each to be combated by a specific serum.

Dr. MENZER replied that by injections of serum of other streptococci a raising of the temperature was produced. His therapeutic results had proved that his theory was right.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

The Tibet Mission and the Hardships of the March.—The Plague Death-roll.—A Successful Septic Tank and Sewage Farm.—Caste Prejudices and Sanitary Improvements.

THE ordinary accounts of the advance of the Tibet mission only briefly refer to some of the hardships of this wintry march. It is not generally recognised that the marching and camping are being done at altitudes unknown and impossible in Europe and that while the sufferings from the cold are severe those from the rarity of the air are intense. A correspondent writes: "The lungs seem unable to do their work. One gasps and pants after the slightest exertion as if about to suffocate. Whilst still this rarefied air can be tolerated, but under exertion air-hunger becomes distressing. The transport animals feel it and the business of bringing them along is painful." The mission camped at Dantu opposite a frozen waterfall 200 feet high. As the march was above the wood line fuel was doled out very sparingly—in fact, only sufficient to cook the daily ration.

None could be spared to light fires for the sake of warmth. Further on Pharo plain an altitude of 14,000 feet was attained. During this part of the march it is stated that at every few yards men sat down, bent double, grasping their heads in their hands. Their faces were purple and working. Still further on came the Tung pass which is higher than Mont Blanc and the air-hunger became still more extreme. Many followers in advancing lay down and would have died from the cold but the column moved them on. Here was another camping ground but again without fuel and with 23° of frost. There are few who can realise the difficulties of this march—in many ways they are unparalleled.

There were 44,783 deaths from plague in India during the week ending April 30th, an increase of nearly 6000 on the preceding week. Of this total no less than 33,953 occurred in the Punjab, an increase of over 9000. Kashmir is the only other place which shows an increase, the deaths having risen from 578 to 627. Improved returns are published from the Bombay districts with 3027 deaths, as against 3723; from the United Provinces with 2965 deaths, as against 4279; from Bengal with 1062 deaths, as against 1439; from Rajputana with 865 deaths, as against 1072; from Central India with 512 deaths, as against 732; from the Central Provinces with 214 deaths, as against 498; from Bombay city with 520 deaths, as against 563; from Calcutta with 270 deaths, as against 440; and from Karachi with 219 deaths, as against 249. Later returns from Bombay city and from Calcutta show still further declines; the outbreaks in the two cities are rapidly subsiding.

A recent report shows a most successful working of the Matunga sewage farm (septic tank system) near Bombay city. There is here a leper asylum and the septic tank installation deals with the sewage. The whole of the effluent is used on a farm of about five and a half acres and the produce from the farm has amounted to 36 tons per acre. Plantains, guinea grass, lucerne grass, and vegetables are grown but the chief out-turn is of karbi and jowar. The fodder crops are sold to the health department for the feeding of bullocks. The profits of the farm wholly maintain the 50 lepers located therein. The gas given off from the septic tanks works an engine which actuates a small centrifugal pump and daily lifts as much of the fluid to the filters as is required. When the effluent, as in this case, is chiefly applied to the land one purification only of the sewage appears necessary, and nearly the whole of the effluent used on the farm comes directly from the septic tank. Otherwise the filter beds are used and they continue to give the same satisfactory results as in 1902.

Caste prejudices in India operate seriously at times against sanitary improvements. Here is an example. The town of Trevandrum wants an improved supply of water and there is a proposal to dam the river 12 miles away and to introduce the pipe system, but caste prejudices oppose a scheme for bringing drinking water along by means of a pipe, as it is said that water touched by a low-caste Hindu would not even be accepted by one of high caste and that the wells (situated in every house compound) would be preferred. To pander with this prejudice it is now advocated to combine irrigation with the supply of drinking water and to have open channels, and the excuse is given that a large area of land might be made productive and that if necessary pipes could subsequently be connected. The danger to the purity of the water by conveyance in open channels, not to mention the additional breeding grounds for mosquitoes, seems to be forgotten.

May 12th.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

Lying-in Charity.

THE annual meeting of the friends and supporters of this charity has recently taken place and from the sixty-first report then read I learn that 914 cases were attended during the year 1903 and the percentage in which medical officers were called in was 5 2. One mother had died and there had been eight deaths of children in the first ten days and one death between ten and 30 days. As representing the only maternity charity in the Midlands the committee had considered it its duty to undertake the training of midwives in accordance with the Midwives Act of 1902. The scheme was now in working order and the charity was prepared to take pupils.

Training of the Feeble-minded.

The Midland Counties Asylum at Knowle is an institution for the care and training of the feeble minded and its thirty-seventh annual meeting has recently been held at the council house, Birmingham, under the presidency of the Lord Mayor. The report then read stated that considerable progress had been made with the work of the institution during the year. The number of admissions was greater than in any previous year and coupled with the increasing number of applicants for treatment was a striking testimony to the favourable estimation of the work and the urgent necessity for its further extension. The scholastic training of the patients received primary consideration and many of the inmates had made considerable progress. The industrial training in carpentry, shoemaking, tailoring, &c., had also received due attention and many of the boys were now rendering useful assistance in those branches of industry; several of the inmates had become excellent wool rug makers. There was a deficit on the year's working of £368 5*s*. 10*d*., which was due chiefly to the appointment of industrial trainers in tailoring, shoemaking, and carpentry, and additional nurses and attendants rendered necessary by the classification of the inmates. Those were entirely new items of expenditure and it was only too apparent that if the work of the charity was to be carried out on up-to-date lines the income must be considerably augmented. The Lord Mayor, in moving the adoption of the report, said there were few questions of greater national importance at the present time than the subject of the treatment and future of the feeble-minded. The question had been allowed to drift for a number of years with the result that their numbers had been largely increased and many of them were to be found in workhouses and prisons. Being crippled in mind they could not withstand the numerous temptations which beset them and therefore they became a moral danger to the State. He was glad to know that the matter was occupying the public mind more and more and it was time the nation became alive to the present condition of many ot its members. The Poor-law guardians and education committee, thanks principally to Mrs Hume Pinsent and her fellow-workers, were taking steps to make better provision for the training and care of the feeble-minded in Birmingham and he hoped that homes would be established all over the kingdom where they could be isolated and properly cared for. For 36 years there had been such a home at Knowle where the feeble-minded children of the Midland counties had been educated, cared for, and trained. He knew the claims on the citizens of Birmingham were numerous, but because the asylum was not within the city was no reason why it should not be included in the local list for support. He trusted the citizens, therefore, would show their appreciation of the work which had been carried on in a very practical manner. The number of Birmingham patients admitted last year was 28, or about one-third of the total number of admissions, and the subscriptions from the city amounted to only £97. Seeing that the average cost of each patient was £35 Birmingham's contribution should have been £970 and consequently it seemed that subscribers outside Birmingham had been helping to keep the Birmingham patients in the institution. Archdeacon Diggle, in proposing a motion sympathising with the objects of the asylum, said that in removing one of the feeble-minded children into the asylum it was not simply that the child itself was benefited but that the family to which the child belonged was released from a very great incubus. He was convinced that if more people would visit the asylum and similar institutions they would not have to complain of the lack of financial support. He was dead against too much State interference but he thought the local education authority in Birmingham was not doing anything more than its duty when it undertook the training of crippled and feebled-minded children. He wished they could do without State help or subsidy but he would rather have that assistance than that the work should not be done at all. Dr. Thomas Savage, in seconding the motion, remarked that it was estimated that one in every 400 of the population was feeble-minded. Those people could not go into lunatic asylums because they were not lunatics and they could not always go into the workhouses. Therefore, such an institution as the one at Knowle was doing an incalculable amount of good on behalf of the community. Mrs. Hume Pinsent, chairman of the

Local Feeble-Minded School Committee, in supporting the motion, said it would be hard to over-value the good done for the mentally defective in the past by the devoted pioneer work of the Knowle and kindred institutions. She appreciated to the fullest extent all that had been done but thought the time had come when such charitable institutions should look to the State for further aid. The way to help the mentally defective had been pointed out by private charity but she was afraid the work was too vast for private charity to cope with successfully. For instance, there were 106 cases under treatment at Knowle last year but in Birmingham they knew of 100 feeble-minded adults and it was estimated that there were 245 feeble-minded children and at least 50 idiots and imbeciles. Thus in Birmingham alone there were 395 individuals needing permanent asylum accommodation. Private charity could not face such a vast number as that. She wished the Knowle authorities could see their way to relieve the Birmingham committee of some of the 50 idiots and if they could not they might join the Birmingham committee in an earnest endeavour to obtain public funds for the provision of some of them other than was supplied by the Poor-law.

X-ray Treatment at the Skin Hospital.

At the twenty-third annual meeting of the friends and supporters of the Skin Hospital recently held the medical report read by Mr. E. Gilbert Smith stated that in the out-patient department the average daily attendance had been 123, as against 115 in the previous year. 150 in-patients passed through the wards and many of the cases were of a severe type, demanding assiduous attention on the part of the nursing staff. Only four deaths occurred and of these two were due to convulsions in children. 82 operations had been performed, all of which resulted in cure or material benefit to the patient. The committee was about to commence treatment by the means of radium. Since the installation of the x ray and electric light apparatus in 1901 230 cases of lupus, cancer, and other chronic diseases of the skin had received treatment in the electrical department. An average number of 24 cases had attended daily from June, 1901, to January, 1904. The sanguine hopes that were expressed when that treatment was first applied for lupus, &c., had not been entirely realised, but results had been obtained which constituted a great advance in the treatment of certain diseases of the skin. The great majority of the cases had shown decided improvement and that had encouraged the patients to continue the treatment. A considerable number had not continued treatment for a long enough period for the rays to have any effect and of those who had been benefited by the treatment a large number had been very irregular in their attendance. The disease had disappeared in ten cases of lupus and in seven of rodent cancer. 20 cases were almost cured and 46 were very much improved. A few patients over 70 years of age and one of 83 had been completely cured of rodent cancer.

May 31st.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Royal Infirmary Site.

A SPECIAL subcommittee of
met on May 19th to take
view of deciding how best to
area left within the infirmary railings now these have been set back for the widening of the surrounding streets, including, of course, the space that will be cleared when the present infirmary buildings are removed. This subcommittee was a very large one and on the motion of the Lord Mayor it was resolved to form a smaller one to consult with the art gallery committee and the free libraries committee in order to prepare if possible a scheme for the building of a free reference library and an art gallery on the site.

The Manchester and Salford Ambulance System

A discussion is going on in Manchester on the subject of the ambulance system both here and in Salford, with the view of its improvement. A short time since (March 23rd) a letter appeared in the local papers from Mr. W. Thorburn, dealing with the question as it would be affected by the removal of the Royal Infirmary from the centre to a suburb, and now a letter, dated May 19th, signed by the chairman and honorary secretaries of the Medical Guild, has been published in which the matter is considered in its wider aspects as affecting both Manchester and Salford generally. Accidents and sudden illness, as it says, may happen to all without distinction of class, and while many of the cases would be most suitably treated at a hospital some would prefer treatment at their own homes. For all these classes the guild considers that a "municipal ambulance and first-aid system" ought to be available. Both Mr. Thorburn and the guild say that the first-aid rendered before removal should be "far more efficient than at present" and that "the somewhat hysterical haste in transit so common nowadays often does more harm than good." The first aid should be as efficient as possible before removal and the guild agrees with the idea that it should be carried out by a properly qualified medical man, also that it would not be necessary or advisable to appoint special emergency medical officers or to equip dressing stations in various districts as lending to delay and expense. The proposition is that the police be "empowered and directed" to summon the nearest medical practitioner who already has a surgery fitted up for dealing with emergencies. In theory the police have now this power "but in practice are exceedingly chary of summoning medical aid lest they should be accused of incurring expense without reason." If this system were carried out the patient would often be properly attended to before the arrival of the ambulance conveyance. The guild suggests the formation of a central board "consisting of representatives of the corporations of Manchester and Salford and of the various hospitals and other public bodies concerned with the coöperation of the medical practitioners of the various districts to concert a thorough scheme of first-aid and ambulance removal in medical and surgical emergencies." Any such scheme would have to be well thought out, but it would tend to the saving of life and to the relief of suffering if the present well-meant but often irregular and happy-go-lucky methods were better organised.

Salford Royal Hospital.

At the last monthly meeting of the board of management of the Salford Royal Hospital a letter was read from the distributers of the Booth Charities stating that they had decided to make a grant of £1000 a year to the hospital. A hearty vote of thanks was accorded to the distributers for their very welcome announcement. These charities come down from the seventeenth century. Humphrey Booth the elder founded a charity in 1630 for "the succour or relief of such poor, aged, needy, or impotent people as for the time being should inhabit or dwell within the town of Salford." The income is derived from land in Manchester and from Government stock and exceeds £16,000 per annum. It is disposed of to about 1050 recipients in sums of 5*s.* or 10*s.* weekly. In 1695 another Humphrey Booth, the grandson of the former one, devised certain premises the income from which was to be employed in the repairs of Sacred Trinity Chapel in Salford and any overplus was to be distributed among the poor of Salford at Christmas, as the money left by his grandfather was. The yearly income is about £1170 and is devoted to repairing Trinity Church and to the relief of the poor. These charities are administered by trustees and the distributers are the Mayor of Salford, the Alderman of Crescent Ward, and the churchwarden of Salford.

Lancashire and Yorkshire Railway Ambulance Work

A gathering of the Lancashire and Yorkshire Railway Company's officials and employés was held at the company's offices on May 18th, when certificates and awards for proficiency in ambulance work were presented by the general manager, Mr. Aspinall, to those who had qualified. The occasion was rendered all the more interesting by the presentation to Mr. F. H. Westmacott who has instructed the ambulance classes, of an electric lamp as a token of appreciation of the work he had done in
kindly feelings towards him on
Mr. Aspinall stated that now 160
96 vouchers, and 46 had gained
G. H. Darwin, who has for many
years identified himself with the ambulance movement, was

Woodhead by June 27th. It is proposed to establish new demonstratorships in surgery and in experimental psychology.—Professor C. S. Sherrington of the University of Liverpool has been approved for the D.Sc. degree.—At the Congregation on May 26th the following degrees were conferred:—

Bachelor of Medicine.—F. D. Nicholson, King's; H. S. D. Browne, Trinity; W. E. Hume, Pembroke; E. Higson, Magdalene; and W. B. Crowfoot and H. J. Shone, Emmanuel.

Bachelor of Surgery.—H. Falk, King's; R. G. Elwell, Trinity; E. Ward, Clare; W. E. Hume, Pembroke; and K. H. A. Kellie, Gonville and Caius.

The Grace for the establishment of a Board of Anthropological Studies was carried at the same Congregation by 102 to 8.—At the Special Congregation for conferring honorary degrees held at Cambridge on May 28th, two of the six honorary degrees in Science were conferred on two distinguished anatomists, Emeritus Professor Retzius of Stockholm and Professor Waldeyer of Berlin. The Public Orator, Dr. J. E. Sandys, in presenting them for the degrees, delivered two speeches distinguished by the happy turns of speech and elegant Latinity so characteristic of him.

CONJOINT EXAMINATIONS IN IRELAND BY THE ROYAL COLLEGE OF PHYSICIANS AND THE ROYAL COLLEGE OF SURGEONS.—At a special examination for the diploma in Public Health held in February the following were successful:—

M. A. Curry, L.R.C.P. & S.Irel., and Edward Carnell, L.R.C.P. Irel.

FOREIGN UNIVERSITY INTELLIGENCE.—*Berlin:* Dr. Georg Levinsohn and Dr. Joh. Herzog have been recognised as *privat-docenten* of Ophthalmology and Dr. Adolf Bickel as *privat docent* of Pathology.—*Breslau:* Dr. H. Reichenbach of Göttingen has been recognised as *privat-docent* of Hygiene.—*Copenhagen:* Professor Hirschsprung is resigning his post as lecturer on Children's Diseases.—*Freiburg:* Dr. Hegar, the well known gynæcologist, is about to retire from his professorship and has been appointed Privy Councillor with the title "Excellenz."—*Gratz:* Dr. Paul Mathes has been recognised as *privat-docent* of Midwifery and Gynæcology.—*Marburg:* Dr. W. Krauss has been recognised as *privat-docent* of Ophthalmology.—*Naples:* Dr. C. Cafiero has been recognised as *privat-docent* of Internal Pathology, Dr. Gaetano Finizio as *privat-docent* of Children's Diseases, and Dr. Vito Capriati as *privat docent* of Electro-therapeutics.—*Strasburg:* Dr. Leopold Rosenthalen, First Assistant in the Pharmaceutical Institute, has been recognised as *privat-docent*.—*Vienna:* Dr. Leopold Freund, Dr. Robert Kienbock, and Dr. Guido Holzknacht have been recognised as *privat docenten* in the use of the Roentgen Rays. Dr. Paul Moser has been recognised as *privat-docent* of Children's Diseases.

CENTRAL MIDWIVES BOARD.—At a meeting of this Board, held at the Board Room, Suffolk-street, S.W., on May 26th, the following business amongst other was transacted. The further consideration was resumed of letters from the Royal Academy of Medicine in Ireland, the Rotunda Hospital, Dublin, the Coombe Hospital, Dublin, and the Belfast Maternity Hospital asking for a modification of the rules of the Board so as to facilitate the admission of Irish trained pupil midwives to the examinations of the Board. After discussion it was resolved that the Privy Council should be asked to sanction the appending of the following note to Rule C.I. (2):

> *Note.*—A certificate to the effect that the candidate has nursed twenty lying-in women during the *eight* days following labour will be accepted in place of the above in cases (1) where the course of special training in a hospital has extended over a period of six months, or (2) where a course of three months' special training in a hospital has been preceded by a full course of training in general nursing.

It was also resolved that the Privy Council should be asked to sanction an alternative form of certificate under Form IV. in the Schedule, to meet the modification contemplated by the above note. It was further resolved that reporters of the recognised medical and nursing journals heaould be invited to attend the meetings of the Board. May`. following figures show the separate numbers of the Compas qualifications at present appearing on the roll: ground-. College of Physicians of Ireland, 1; Obstetrical to a railw of London, 1434; Rotunda Hospital, 64; Coombe so that th 28; Queen Charlotte's Hospital, 99; Liverpool as they will Hospital, 57; British Lying-in Hospital, 4; aternity Hospital, 49; St. Mary's Hospital, Manchester, 85; Manchester Maternity Hospital, 1; City of London Lying-in Hospital, 10; Royal Maternity Hospital, Edinburgh, 11; Salvation Army Maternity Hospital, 5; National Maternity Hospital, Dublin, 2; and Women in *bonâ fide* practice July, 1901, 3480. Total enrolled, 5330.

THE NOTIFICATION OF MEASLES.—The Wigan sanitary committee has adopted for a further period of three years the following recommendation of the medical officer of health as to the voluntary notification of first cases of measles in a household: "Notification of the first case of measles occurring in any house shall be made to the sanitary authority on the same terms as compulsory notification of other infectious diseases."

GLASGOW OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.—The following have been elected office-bearers of this society for the session 1904–05: Honorary President, Dr. C. J. Cullingworth, London; President, Dr. J. K. Kelly; Vice Presidents, Dr. A. Richmond and Dr. John Lindsay; treasurer, Dr. G. N. Turner; secretary, Dr. G. Balfour Marshall; editor of Transactions, Dr. A. N. McLellan; reporting secretary, Dr. A. Louise McIlroy; pathologist, Dr. John H. Teacher; members of council, Dr. J. Nigel Stark (past president), Dr. Samuel Alexander, Dr. D. Watson, Dr. R. C. Adamson, Mr. Campbell Syme, Dr. W. L. Reid, and Dr. W. Ritchie.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Ludwig Wilhelm Liersch of Kottbus, author of "The Last Illness and Death of Frederick the Great," "The Left Hand," and various ophthalmological papers. He studied medicine in the early "fifties" in Paris, London, and Edinburgh, after having qualified in Germany.—Dr. E. Demange, professor of forensic medicine in Nancy.—Dr. Gilles de la Tourette, *agrégé* of the Paris Medical Faculty.—Dr. Carlo De Vincentiis, professor of ophthalmology in the University of Naples.—Dr. Georg Karamitsas, professor of medicine in the University of Athens. He was born in 1834 in the island of Lesbos and studied at Athens and afterwards at Würzburg, where he took his degree. He then returned to Athens and taught pathological anatomy in the university, subsequently becoming professor of medicine. He founded the medical journal *Asklepios* and edited the Greek edition of Niemeyer's "Special Pathology and Therapeutics" and several other translated works.

UNIVERSITY OF ABERDEEN.—A meeting of the University of Aberdeen Anatomical and Anthropological Society was held on May 28th at Marischal College, Professor R. W. Reid being in the chair. Dr. G. Stoddart read a paper entitled "Statistics obtained from Observations of the Eyes of 400 Students." The observations had been made in the anthropometrical laboratory at Marischal College for the most part by Dr. C. H. Usher, and with his assistance Dr. Stoddart had compiled the statistical results, a compilation which is unique in the history of British university anthropometry. Dr. Stoddart reviewed the subject under several heads. As regards acuteness of vision the statistics obtained compared favourably with those obtained by other observers. The proportion of Aberdeen students with short sight was shown to be much smaller than that found by similar observations in German and American universities—namely, 18·7 per cent., as compared with 28 per cent. in some American universities and 59 per cent. at the University of Breslau. Another interesting point brought out by the observations was that short sight was much more frequently found in students coming from towns than in those from country districts. The prevalent idea that in short-sighted eyes the pupil was usually larger than in eyes with normal vision was contradicted by these observations which showed a larger average pupil in long sight than in short sight. With regard to the colour of the eye, it was shown that dark eyes predominated in persons having dark hair and skin. In the group of those with red hair a larger proportion of the eyes were of a grey colour than in the other groups. Acuteness of vision was found to depend little, if at all, on the size of the pupil or the colour of the eye. Light-coloured eyes were found to have a slightly larger pupil than dark or grey-coloured eyes. 3 per cent. of the students were found to be colour-blind. After a short discussion on the above subject a paper was read by

Mr. M'Kerrow on the Inhabitants of Uganda, illustrated by ten skulls of Wa Soga people presented to the anatomical museum by Dr. Ian Rose, late medical officer, Uganda Railway.

CENTENARIANS.—Two centenarians in North Wiltshire have just been celebrating their birthdays. Mrs. E. Winter of Cricklade has attained her 104th anniversary and Mrs. M. Vines of Bradenstoke has attained her 102nd.

REMUNERATION FOR EXTRA WORK.—At the meeting of the Bristol board of guardians held on May 20th a gratuity of £10 was awarded to Dr. C. Morley Phillips, medical officer of the tenth district of the Bristol union, for extra services rendered by him in connexion with the outbreak of diphtheria at the Grove Home for Girls, Brislington.

A UNIVERSITY FOR THE DON PROVINCES.—A movement to found a university in Novotcherkask, says the *Pharmaceutical Gazette*, to meet the educational wants of South-East Russia and the Caucasus, is warmly supported by the local authorities and the first day's subscriptions towards the realisation of the project reached the sum of 30 000 roubles (£3000).

GUY'S HOSPITAL LADIES' ASSOCIATION.—The ninth annual general meeting of this association was held at the hospital on May 28th. The President of the Association, Princess Christian, was present at the meeting and was received by Mrs. Benyon and Mrs. Cosmo Bonsor. Before the meeting several ladies, as secretaries of local branches, were presented to Her Royal Highness. The minutes of the last general meeting having been read and signed by Her Royal Highness as correct, Mrs. Pye-Smith, the honorary treasurer, presented the accounts which were approved of. The annual report, which was read by Mrs. May H. Shaw, the honorary secretary, contained a recommendation from the committee that £150 should be voted from the funds to support three beds in the maternity ward. It was announced that two new branches had been instituted during the year. The reports of the 14 local branches were read and proved that all were in a highly satisfactory state. A vote of thanks to Her Royal Highness for presiding was moved by Mrs. Benyon, seconded by the Countess of Bective, and carried with acclamation, after which Her Royal Highness inspected the needlework contributed during the year and was entertained at tea.

CRYSTAL PALACE JUBILEE.—Great preparations are being made for the forthcoming celebration of the Crystal Palace jubilee. On June 10th, 1854, the Crystal Palace after being transferred from Hyde Park was opened in state by Her Majesty Queen Victoria, accompanied by the Prince Consort and His Majesty King Edward VII. (then Prince of Wales) and it has been decided to celebrate the jubilee of this event by a grand concert on Saturday, June 11th next. The undertaking has been honoured by the patronage of their Majesties the King and Queen and it is intended that the festival shall be in keeping with those many gigantic musical functions associated with the name of the Crystal Palace. Sir August Manns on the forthcoming occasion will occupy his old position as director of the choir and orchestra, which will number over 3000 performers, and the artistes will be Madame Albani, Miss Agnes Nicholls, Miss Muriel Foster, Mr. Ben Davies, and Mr. Santley. Mr. Walter W. Hedgcock will be the organist. Messrs. C. T. Brock will give a great display of fireworks.

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.—The annual general meeting of this society was held on May 18th at 11, Chandos-street, W., Mr. Christopher Heath, the President, being in the chair. From the report read by the secretary it appeared that 12 new members had been elected in 1903, four had died, and three resigned, leaving 297 members at the end of the year. Two widows were elected and three had died; 53 were in receipt of grants on Dec. 31st, 1903. Six orphans had been granted assistance and one had become ineligible, leaving 15 receiving grants. A sum of £3308 10*s.* had been distributed during 1903. The expenses of the year had been £244 19*s.* 9*d.* The receipts available for payments had been £3302 1*s.* 10*d.*, a deficit of £251 17*s.* 11*d.* on receipts and payments owing to change of investments and half a year's interest only paid on the new stock. A small legacy of £25 had been received. A vote of thanks to the editors of the medical journals was passed unanimously. The following gentlemen were elected to fill the vacancies in the court of directors: Mr. A. W. Green, Mr. E. G. C. Snell, Mr. E. H. May, Dr. C. Godson, Mr. W. J. N. Bell, Dr. W. C. James, and Dr. Samuel West. A vote of thanks to the chairman closed the proceedings.

TORBAY HOSPITAL.—The sum of £1215 has been already received by the committee of the Torbay Hospital towards the £2000 required for the proposed children's ward in that institution, and an anonymous donor has promised £100 provided that the whole amount is forthcoming by the end of June.

DONATIONS AND BEQUESTS.—Mrs. Isabella Burn-Blyth, of Woolhampton, Berks, by her will bequeathed £100 to the Bishop of Mauritius for the benefit of the Medical Mission at Mauritius, £100 to the Reading Hospital, £50 to the Newbury Dispensary, and a like sum to the Medical Mission at Woolhampton.—Under the will of Miss Susan Sympson, of Minster-yard, Lincoln, subject to some specific bequests, £100 have been bequeathed to the Lincoln County Hospital, £100 to the Lincoln General Dispensary, £100 to Epsom College, £100 to the Midland Institution for the Blind, £100 to the Mablethorpe Convalescent Home, and £100 to the Alexandra Hospital at Woodhall Spa.—The Drapers' Company has voted a grant of £500 towards the reconstruction of the isolation accommodation and the erection of special wards for whooping-cough patients now in progress at the East London Hospital for Children, Shadwell, E., conditionally that the total amount required—namely, £10,000—is subscribed within a reasonable time.—The Coal and Corn and Finance Committee has resolved to recommend the Court of Common Council of the City of London to contribute the sum of £2000 as a donation towards the fund for the rebuilding of St. Bartholomew's Hospital.—The Great Western Railway Company has sent a donation of £250 towards the same object.

ASYLUM WORKERS' ASSOCIATION.—The annual report for 1903 shows that since the previous report appeared there has been a diminution in the number of ordinary members but an increase in subscriptions. Fluctuations of this sort must be expected to occur in such an association until better enticements are offered to induce permanence of service by asylum staffs. Provisions for securing adequate pensions are much desired and the matter will be urged by the association upon Parliamentary candidates. To encourage long and meritorious nursing service in asylums two gold and two silver medals annually are awarded by the association. The subject of the proposed State registration of nurses has been consided by the executive committee and the claims of both male and female mental nurses to consideration have been successfully urged upon the promoters of each of the Bills now before the House of Commons. The financial statement for 1903 showed that the total receipts with last year's balance amounted to £472 10*s.* 7*d.* and that the payments amounted to £385 15*s.* 4*d.* 21 nurses and attendants received grants from the "Homes of Rest" Fund and benefited by the rest and change of environment so secured. By this fund members are enabled to stay at health resorts in any part of the kingdom. The Reading Union promotes the study of standard light literature amongst asylum workers. Mr. Rider Haggard has given a special prize in this connexion. The eminent services during seven years of the retiring President, Sir James Crichton-Browne, are gratefully referred to and Sir John Batty Tuke has been nominated as his successor.

Parliamentary Intelligence.

HOUSE OF COMMONS.

TUESDAY, MAY 31ST.

The Manufacture of Serum.

[illegible]

this statement he would [illegible]

prohibit the manufacture of serum in laboratories licensed under the Vivisection Acts.—Mr. Akers-Douglas said: The manufacture of serum is a procedure outside the scope of the Cruelty to Animals Act, and I am not prepared to act on the suggestion of the hon. Member. As regards the first part of the question, I presume the hon. Member refers to the pamphlet which the Lister Institute has thought it right to issue by way of a warning (in order to prevent unnecessary alarm) and in which it is stated that in some cases certain results such as rashes and joint pains may follow the therapeutic use of sera. These results, it is stated, are of a temporary nature and cause no bad after-effects. The words of the pamphlet with reference to diphtheritic paralysis do not convey to my mind the meaning attributed to them by the hon. Member.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

COMPENSATION FOR INJURIES AND INSURANCE.

To the Editors of THE LANCET.

SIRS,—I have received letters from two medical men asking to be allowed to be present, on behalf of an insurance company, at an operation upon a hospital patient of mine for a condition following an injury. I shall be glad if you will express an opinion as to the desirability or otherwise of permitting this practice.

I am, Sirs, yours faithfully,
May 28th, 1904. W.

*** There is much to be said on both sides. On behalf of the medical men representing the insurance company it may be urged that they may, by being present at the operation, have an opportunity of estimating more exactly the actual injury done and the chance of a perfect recovery. On the other hand, it can hardly be necessary for these medical men to be present, for the surgeon under whose care the patient is is certainly in the best position for expressing an opinion as to the condition of the patient The main difficulty arises from the fact that these two medical men represent the insurance company and thus they are liable to take an *ex parte* view of the injury and perhaps even of the operation and of the mode in which it is performed. On the whole, we feel that it is hardly possible to refuse permission to be present to qualified medical men, but we think that they should be very careful not to let their zeal for the interests of the insurance company with which they are connected over ride their judgment and so permit them to criticise the treatment adopted by the surgeon in charge of the case —ED. L.

MADAME MAGDALEINE.

ON the evening of May 29th Madame Magdaleine, of whose performance in Paris our Paris correspondent gave our readers an account in THE LANCET of May 14th, made her *début* in London under the auspices of the Sunday Concert Society at the Grafton Galleries. Madame Magdaleine, who is a very pretty and graceful woman of an obviously Slav type, is claimed to give her "musical interpretations" while in a state of hypnosis. She appeared on the platform accompanied by M. Magnin, professor at the Paris School of Magnetism. He held her hands and also made the usual hypnotic passes, upon which she apparently fell into a hypnotic state. Music was then played when Madame Magdaleine illustrated the various moods reflected in the music by appropriate poses and dances. The musical instruments were a violin, a piano, a Mustel organ, and, if our ears did not deceive us, a celesta. To the peculiar quality of this last Madame Magdaleine seemed specially sensitive. We must confess to being very doubtful about the reality of the apparent hypnosis whatever may have been the case at the Paris *séance*, but be this as it may, Madame Magdaleine is a thorough artist and her performance was well worth seeing.

A WEEK'S SUICIDES IN MANCHESTER

SIX suicides were recorded in Manchester last week. So far as was ascertained two were from ill health, one was attributed to "mental depression," and in the other three the victims had been out of work for some time. Two of the men drowned themselves, a woman in ill health hanged herself; a commercial traveller cut his throat with a razor; one man, out of work, took carbolic acid, and the sixth, also out of work, drank oxalic acid. No mention is made of "drink" having anything to do with the ill health, the mental depression, or the being out of work, but it is not improbable that it was an important factor in most of the cases.

ENTERPRISE.

no qu
1892. F.R C S. (E), 1901. *1897 to 1899.*—Assistant and house surgeon, Golden square Throat Hospital, a period of 18 months—six months assistant, 12 months house surgeon, clinical assistant to the hospital previously. House surgeon, Central London Eye Hospital, July–Nov., Gray's Inn road—four months. *1899 (Nov) to 1901 (April).*—House surgeon to the Royal Westminster Ophthalmic Hospital in King William street, Strand, W. *Dec., 1901*—Commenced practice West Hartlepool as oculist and aurist. Appointed ophthalmic surgeon to the town hospital here last year.'

STRIKING A PATIENT IN A LUNATIC ASYLUM.

AT the South-Western police-court recently a female attendant at the Middlesex County Asylum was summoned for striking a female patient. The evidence showed that the defendant was annoyed by the patient catching hold of her and in a moment of irritation slapped her in the face. Dr. L. W. Rolleston, one of the medical officers of the asylum, gave evidence that the blow was a severe one and that the patient was in indifferent health besides suffering from melancholia. In the circumstances the fine of 40s. imposed, together with the dismissal of the attendant from her post, will serve to remind those in a like position that the regulations framed for their guidance can be stringently enforced when the occasion requires it. The three hundred and twenty-second section of the Lunacy Act, 1890, enables serious cases of ill-treatment of patients to be punished upon conviction under an indictment by imprisonment or by fine. Upon summary conviction under the same section a fine not exceeding £20 or less than £2 may be imposed.

A QUESTION OF TREATMENT.

To the Editors of THE LANCET.

SIRS,—May I ask your opinion or of any of your readers on the following case. The patient, a man, fell at dusk one evening while walking over rocky ground. To break his fall he put his right hand forward which saved him, but on getting up found he could not move his wrist. On examination it was found that the lower end of the ulna was projecting backwards. No fracture could be found and there was no pain except on the anterior and posterior end of the ulna. It was replaced but slipped back, more especially on supinating the forearm. A temporary splint with a pad over the ulna was put on and when the swelling had disappeared the hand was put up in plaster-of-Paris in the semi-pronated position. After three weeks it was taken down but was practically the same. It is now nine months since the accident and the lower end of the ulna is still very moveable and is only kept in position with a strap. I recently saw a similar case in a young soldier who had been treated six months before for a Colles's fracture. I need hardly say there was no fracture but the condition I have above described. This condition was diagnosed as a dislocation of the lower end of the ulna backwards, the force having torn the ligaments, particularly the broad attachment of the triangular ligament. I would like to know of any others who have seen this accident and their ideas on the subject. What is the best treatment? I know of no description of this accident and have not seen one before. I am, Sirs, yours faithfully,

June 1st, 1904. PROMITTE VIRES.

*** It is somewhat difficult to express a decided opinion on the facts submitted to us, but we should be inclined to think that the lower end of the ulna had been dislocated backwards, the internal lateral ligament of the wrist-joint and possibly the triangular ligament also having given way. After so long a period as nine months it will be very difficult to induce the head of the ulna to retain its right position. The best treatment will be to apply such a splint as will hold the lower end of the ulna in position without interfering with the use of the hand. A leather splint would be best; it would probably need to be worn for some months.—ED. L.

99 PER CENT. ADULTERATION.

THE name of Patrick Lynch, grocer, of Burnley, should surely be recorded, as the owner of the name has attained about the greatest possible height of fraud in the adulteration of butter. On May 18th he was fined the maximum penalty—£50 and costs, or three months' imprisonment—for selling as butter a mixture of 1 per cent. butter and 99 per cent. foreign fat and for selling margarine unlabelled. There were previous convictions against him. The roguery might perhaps be equalled but scarcely the impudence.

NORWEGIAN SANATORIUMS.

To the Editors of THE LANCET.

SIRS,—I shall feel obliged if any of your readers can give me any information about Gansdal, Norway, from a medical point of view. I believe there is a sanatorium or hotel there which is about 3000 feet above sea level. Is the food good and suitable for people of weak digestion and is the climate much the same as the health resorts in Switzerland at the same altitude? Are the sanitary arrangements good?

If you can give me any information concerning the place in your next issue I shall be grateful. I am, Sirs, yours faithfully,

May 30th, 1904. PHYSICIAN.

PATENT ABSORBER BRIAR.

WE have received from Messrs. Charles Crop and Sons of Brooksby Works, Brooksby-walk, Homerton, London, E., a patent pipe which they have recently designed in a way calculated to minimise the deposition of tar oils or moisture in the stem. The bowl consists of two sections: in the larger one the tobacco is burnt and in the smaller section is a porous "magnesia carbon" plug or absorber. The smoke takes a downward direction from the bowl proper and then ascends through the absorber, finally emerging at the top through the stem. From one or two trials it appears that the object is gained, for the stem keeps dry and free from oily matters while the smoke is cool and "sweet." The design is not artistic and the appearance is clumsy. The absorber may be renewed and replaced from time to time as it gets foul.

WANTED—A HOME.

To the Editors of THE LANCET.

SIRS,—Can any of your readers inform me of a home which would receive a cottage woman, 72 years of age, bedridden, as a result of rheumatoid arthritis? The maximum sum she can pay is 10s. weekly.

I am, Sirs, yours faithfully,

May 30th, 1904. INQUIRER.

THE SUPPLY OF ICE FOR DOMESTIC USE.

MESSRS. Lehmann and Co., Limited, of Hannam's Ice Works, Gravesend, writing with reference to our remarks upon the above subject in an annotation in THE LANCET of May 28th, p. 1521, state that they supply ice in small quantities made from distilled water and for domestic use and that during the summer they have two vans out every day covering their district. They also offer ice safes for hire at very low rates. We wish this scheme success and should like to see it extended to all parts of the country.

◆

M.Sc., Liverpool.—The subject about which our correspondent inquires is dealt with in treatises of medicine, but the fullest special account which we know of is an article by Dr. Boy-Teissier in vol. vii. of the "Twentieth Century Practice of Medicine." The late Professor George Balfour's book on the "Senile Heart" may also assist our correspondent.

E. P.—We cannot undertake to answer our correspondent's question on the knowledge at our command. The amount of the fee charged must depend upon the financial status of the patient. When the fee charged for an ordinary visit is, say, 7*s.* 6*d.*, one guinea would be a fair fee for the operation named.

Inquirer.—(1) P. Chalmers Mitchell's "Outlines of Biology" (Messrs. Methuen, Essex-street, Strand, London, W.C., 6*s.*), and some of Professor Huxley's treatises. (2) Applications should be made to the secretaries of the examining bodies in question.

Diver's Palsy.—*We agree with our correspondent but do not think that* any good purpose would be served by reopening the question in our columns.

Wealdstone.—We do not think that the name of the practitioner should appear on the handbills in question.

G. W. (*Birmingham*).—The action of the druggist was questionable.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (6th).—London (2 P.M.), St. Bartholomew's (1.30 P.M., St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

Will Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them! Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are :—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, MR. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND

An original and novel feature of "The Lancet General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in The Lancet.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. Charles Good, The Lancet Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

The Lancet can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 31 Rue Bapts, Asnières, Paris.

THE LANCET

SPECIAL SUPPLEMENT

IN SUPPORT OF THE

METROPOLITAN HOSPITAL SUNDAY FUND

Published in aid of the Appeal to be made on Sunday, June 12th, 1904.

> "Our part is to choose out the most deserving objects and the most likely to answer the ends of our charity; and when this is done all is done that lies in our power. The rest must be left to Providence."
>
> BISHOP ATTERBURY.

ONCE more the time has come round for us to make our Annual Appeal on behalf of the Metropolitan Hospital Sunday Fund, and as usual we address a wider public than that by which the pages of THE LANCET are usually read.

The suffering poor of London, and those who with difficulty carry on the hospitals of London in order to afford them relief in time of injury or disease, owe a heavy debt of gratitude to the congregations attending the various places of worship in the metropolitan district on Hospital Sunday, and to all other contributors who have made the Fund what it is. Since 1873 their gift has amounted to something over a million and a quarter sterling; an average has been established during the past few years of which those who inaugurated the Fund and those who now organise it have every reason to be proud, and in each of the last two years all previous records have been exceeded. But if the amounts raised in recent years have been satisfactory, and have on two other occasions doubled some of the modest totals which were attained soon after the inauguration of the Fund in the "seventies," the effort required in order to keep them at this high level, and, if possible, to maintain the same rate of progress, is greater, and the anxiety lest there should be a falling off presses heavily not only upon those who collect and distribute the amount obtained but upon the hospitals who receive it. It is in no spirit of selfish eagerness to acquire credit that those who organise the Fund desire that its annual total should be no lower than on previous occasions; it is because they know that every sovereign that can be obtained is needed, and that any falling off, whether small or great, must be *felt in direct loss of efficiency by the hospitals.*

We urge no new reason each year for giving: we claim no originality for our reiterated Appeal. It is the old story of the poverty of the poor, and of the suffering of the sick and injured in a huge city where poverty and suffering ever dwell side by side with wealth and luxury. In the great army of our workers there must always be some ready to fall by the way, who, when their physical health fails, can never hope to regain their place in the ranks until health is restored to them. It is on behalf of these that we urge our Appeal for the hospitals. We urge it upon all because poverty and sickness know *no distinction* of creed and fall alike upon the worthy and upon the undeserving, and we ask it of rich and poor because all can help according to their power, and because in a population of something like five millions the small gifts of the less wealthy will amount to a goodly sum if all can be stimulated to contribute. In 1904 we urge the necessity of a special effort because there appears to us to be a danger lest without it there may be some diminution owing to special circumstances to which we will refer. We urge it not because we can promise to those who give any direct manifestation of gratitude on the part of those who receive, but because they will have as their reward the consciousness of a good act performed, and of the exercise of that kindness which

> "like light speaks in the air it gilds."

We have on previous occasions called attention to the necessity that those who annually contribute to the Fund at the places of worship which they attend should not only give themselves, but should do their best that others may not forget, and we venture to reiterate this reminder. Our Appeal is not only to the generosity of the wealthy: it is for the universal contribution of all classes.

The Class succoured by Hospitals.

The institutions for the assistance of which the Metropolitan Hospital Sunday Fund is collected, and to which it is distributed after careful inquiry into the work done by them, open their doors to those only who would otherwise find medical and surgical aid beyond their reach. The great London hospitals recognise neither creed nor character as qualifications for admission to their wards. They do not exclude the vagrant or the otherwise undesirable and undeserving, nor are "previous convictions" entered in the history of their cases. Those, however, who are principally benefited by them are the working poor, suffering temporary incapacity through illness or accidental injury, and it is on their miserable behalf that we most earnestly plead. Those who visit our hospitals and inquire into the life stories of their inmates find the tramp and the loafer there, no doubt, but such as these generally have resort to the workhouse before they have reached a stage at which medical aid has become a necessity for them; the union infirmary meets their requirements, and it is there that they find their needs attended to. A large proportion of the causes which fill the wards of our hospitals do not affect them. The accidents which crush and maim, and many other matters which require skilled treatment in suitable surroundings, are the direct or indirect result of toil in factory and workshop, in the dockyard, upon the scaffolding, and in the busy turmoil of our crowded streets. Drink and other reasons which to some extent may seem avoidable are no doubt responsible for many cases which receive hospital treatment, but the bulk remain of the indicated character, and all are treated with the same care and kindness. The worker who may be able to keep his family together, with, at any rate, a roof over their heads, and a certain amount of food for their sustenance, can provide no home where they can be treated or nursed when health has failed or an accident has occurred, and to such as these there would be no alternative but death were the hospital not there to receive them. The hospitals are for the poor, without distinction, but it is by the worker in distress and by his helpless wife and children that their aid is most highly prized. The hospital comes to their aid, representing charity of the finest character in its most prepossessing form. It is the charity of those in better circumstances to their poorer brethren, but it is a free gift which is accepted in the day of necessity, without the feeling of any shame or slur attaching to it.

To whom the Appeal is directed.

The Appeal on behalf of the hospitals of London is made to all without distinction of rank or of religion, and without question as to whether the giver be wealthy or not. If he will give according to his power, if only he will not forget to contribute freely as his means may allow, the hospitals will accept his gift with gratitude. The table published herewith, which records the progress of the Metropolitan Hospital Sunday Fund, contains a special list in which are mentioned, under the heading of "Donations," many noble offerings. Contributions of £1,000 are frequent among these; a donation and a legacy of £5,000 each are to be found among them. In 1895 the late Mr. Barney Barnato and his friends raised and gave between them £10,000; in 1901 Sir F. Cook gave £4,000, and for the last five years record is made of the princely generosity of Mr. George Herring, which in 1904 is to be renewed. These are instances taken from a long list of much-appreciated gifts, and those who compare the special donations with the total of the Fund for each year will see how important a proportion they form of the whole. We would invite the wealthy to consider whether such gifts as they may contemplate devoting to charitable purposes during the coming season could be more worthily bestowed than upon the Metropolitan Hospital Sunday Fund. Could they give to any object having greater needs to meet? Could they give in any direction with greater certainty that their gift would be wisely and economically administered, and that its object would be secured by business-like methods and the exercise of scrupulous care?

We would, however, invite those who are not blessed with great worldly affluence also to contemplate and to consider the special donations, and we would point out to them that the gifts of Mr. George Herring for the past three years have amounted to one-quarter of the whole amount contributed by others to the Fund. It may be added that Mr. Herring has been and is willing to increase his gift in the same proportion so as to raise the total to £100,000, should the contributions of others amount to three-quarters of that sum. At present no near approach has been made to the fulfilment of this condition, but even though it may be at present beyond what we can reasonably contemplate, it may still be suggested that the general giver might endeavour to increase his offering, and, above all, to see that the Fund is not forgotten by his friends. The anonymous gifts of the congregations attained a record figure last year; let us hope that this year that record will be exceeded.

The Hospital Sunday Fund does not catch the eye of the passer-by through the agency of collectors at street corners; indeed, the majority of its contributors only have an opportunity to give should they attend some place of religious worship. Hence those who do not attend public worship in London may forget the Fund, and those who do may come provided, with no more than the donation which they devote to the ordinary weekly collection. We would ask those who do not have the opportunity to contribute in person nevertheless not to forget the Fund, and we would press those to whom the collection bag or plate is handed to make Hospital Sunday a special occasion.

We have referred above to public worship in London as if collections for the Metropolitan Hospital Sunday Fund were made in the metropolis only. This is not, strictly speaking, the case; but it is a matter of regret that outside the metropolitan and suburban district a small number only of places of worship hold collections for the hospitals of London, although patients are received in the wards from all parts of the country, and although such a collection affords the only opportunity of contributing which the class immediately benefited is likely to have.

STATISTICS OF HOSPITAL WORK IN LONDON DURING THE YEAR 1903.

* We reproduce the term "General Hospitals" as employed by the Council of the Metropolitan Hospital Sunday Fund.

Why a Special Effort is necessary.

There is a necessity for special exertion on behalf of the metropolitan hospitals to which we would direct attention in the present year. This arises from no exceptional feature in the health of the public likely to exhibit itself during 1904-05. It is due rather to causes which are likely to act prejudicially to the Metropolitan Hospital Sunday Fund and to the individual institutions which depend largely upon the generosity of the public for their annual incomes. The effect of the late war is being felt in high taxation, and in the East a war in which this country is happily not involved casts a shadow over the whole of the civilised world. Trade is admittedly not at its best, and many are feeling the effect of reduced incomes from invested capital and of the lessened capital value of securities. In these circumstances it is almost inevitable that charities should suffer to some extent, and it is for this reason that we would urge upon all the necessity for exertion in order that our noblest institutions may not have their efficiency curtailed. With increasing population, with bad times, and with greater need among the working-classes, the demand upon their resources will be greater, not less, than in more prosperous years. Moreover, there is no need to disguise the fact that the hospitals have enemies, although they have many friends. The "anti-vivisectionist" of all the army of "anti" faddists is, no doubt, one of the most amiable and well-meaning persons in private life. We have no desire to upbraid him unduly, or to hold him up to ridicule, even though his methods of controversy do not commend themselves to us by scrupulous fairness or by a temperate and candid acknowledgment of facts. He is, however, entitled to hold his opinions as long as they do not prejudicially affect his helpless neighbours. If on the ground that experiments u[illegible]n animals are made in the laboratories and [illegible] schools of our hospitals he prefers not to [illegible] to the Metropolitan Hospital Sund[illegible]ld scarcely even urge him to alter views which possibly afford him satisfaction; we do, however, protest against his endeavouring to persuade other persons not to give. Moreover, we do not conceal from ourselves the fact that "the anti-vivisectionist," in spite of the general good sense of the English nation, has some effect upon the subscription lists of our hospitals. Every sovereign diverted by such an agency is reason for extra exertion on the part of others in order that the

poor may not suffer in proportion to the loss inflicted.

One class of attack the givers to the Metropolitan Hospital Sunday Fund can at all events feel that they are directly helping to repel. Every now and then prominence is given in the newspapers to the fact that a case, the serious nature of which was not recognised, was refused admission to a hospital because all the available beds were full. It is possible that this may be made public in the course of an inquest at which the hospital is not represented. A coroner's jury, ignorant of the true state of the case, is allowed to make observations with reference to the management of the hospital, and possibly damages it in the eyes of the public. That in any hospital no bed is available upon a given occasion is due to the fact that the hospital has already opened its doors as wide as its straitened means will permit. Enlarge those means, increase the number of its beds, and, although it is unlikely that the supply will meet the demand, at any rate the powers of the institution for dealing with unforeseen emergency will be increased correspondingly.

The Gain to the Giver.

Let no one who gives to the hospitals, or who ponders whether he shall do so or not, think for a moment that the poor are not grateful for the aid afforded, or that the help is not real. Two years ago, in our Supplement, we recorded the words of patients spoken in the wards to our Special Commissioner. The patients were invited to mention the circumstances in which they lived and the cause of their presence in the institution. Prominent among the cases noted were those of strangulated hernia: a condition which, as all know, may occur, without any accident in the ordinary sense taking place, to any working man or woman, and which must end fatally if the operation necessary to reduce it be not performed at once. Three or four were cases of cancer, two were of ruptured spleen, another patient, a child, had been operated on for an appendicitic abscess. What chance of life would these have had had the hospital

[1] In 1884 £4500 was received from the managers of the International Health Exhibition.

[2] In 1885 a special donation of £1000 was received from Dr. James Wakley, Editor of The Lancet.

[3] In 1886 a further special donation of £1000 was received from Dr. James Wakley.

[4] In 1887 a legacy of £1000 was paid by the executors of the late Dr. James Wakley.

[5] Including legacy of £1003 14s. from the executors of the late Mr. Thomas Crouch.

[6] In 1891 donations of £5000 from the late Duke of Cleveland, &c., and £1000 from Sir Savile Crossley, Bart., were received.

[7] In 1892 Sir Savile Crossley gave a further £1000; and a legacy of £105 was paid by the executors of the late Dr. H. E. Price of Brighton.

[8] In 1893 Sir Savile Crossley gave a further donation of £1000.

[9] In 1894 a legacy of £5000 (less duty) was paid by the executors of the late Mr. W. J. Whitaker, and Sir Savile Crossley gave a further donation of £1000

[10] In 1895 Messrs. Barnato and Friends gave a donation of £10,000; £3400 was received from the Stock Exchange through Messrs. Pym, Vaughan, and Co., and Messrs. Burdett and Harris; Lord Iveagh gave a donation of £1000; Sir Savile Crossley gave a further donation of £1000; and Mr. J. B. Robinson gave £1000.

[11] In 1896 Sir Savile Crossley gave his sixth donation of £1000, and legacies were received from Mr. John Smith of £500 and Mrs. May Evans of £172 9s. 4d.

[12] In 1897 Sir Savile Crossley gave his seventh donation, amounting this year to £500.

[13] In 1898 Sir Savile Crossley gave his eighth donation, amounting this year to £500.

[14] In 1899 Mr. George Herring gave £10,000; Mr. J. Lane Densham gave £1050; and Sir Savile Crossley gave his ninth donation of £500.

[15] In 1900 Mr. George Herring gave a further donation of £10,000; and Sir Savile Crossley gave his tenth donation of £500. An anonymous donor, "F. H.," gave £1000; and £1090 were received from the estate of the late Thomas King.

[16] In 1901 Mr. George Herring gave a further donation of £10,000, and Sir F. Cook, Bart., M.P., gave a donation of £4000.

[17] In 1902 Mr. George Herring gave a further donation amounting to £11,575, and Mr. Charles Morrison gave a donation of £1000.

[18] In 1903 Mr. George Herring gave a further donation amounting to £12,302.

not been there to receive them? What chance of successful operation or of nursing could they have had in the crowded and insanitary homes in which the congested conditions of life and labour in London compel the poor to live? As it was, they not only had their lives preserved and their health restored exactly as though they had boundless financial resources at their command, but in those cases where the nature of the injury demanded instant operation they gained by the fact that it was performed in the best possible surroundings without delay. One of those interviewed appraised the aid that he had received in rather quaint fashion to our Commissioner. He was an elderly Hebrew, who had been brought to the hospital very collapsed, suffering from a strangulated hernia, and after an operation which had lasted over an hour his life had been saved. Speaking of what had been done for him, he repeated earnestly several times, "I could not have had anything better, not for five pounds; no, not for five pounds, and it was all free." It would have surprised him had he been told the fees which would have adequately rewarded the surgical skill and nursing provided for him had he been in a position to afford payment, but five pounds was the figure selected by him as a sum of unimaginable magnitude in order to express his gratitude in appropriate terms. In the Supplement referred to were quoted the words of another patient who was being slowly nursed back to life and strength after the operation entailed by a fractured pelvis and a ruptured bladder; he said, "Not the King of the country could have had better care than I have had." If His Majesty the King met with the accident which this dock labourer met with, his chances of life would lie in the immediate as well as efficient aid which hospital practice alone would enable his surgeons to supply.

An Appeal to those who might forget.

There is an increasing prevalence of the custom of week-end parties in country houses and of week-end absence from London on the part of those who normally inhabit it. To this may be added the fact that many who work during the week seek recreation on Sunday and perhaps attend no place of worship at all. It is not the duty of THE LANCET to do more than record the facts, though their significance does not escape us. Upon all of these we would urge that they should not forget their poorer brethren. The health and strength which they spend in enjoyment, or seek in leisure, are to many working-men absolutely necessary if life is to be lived at all. It is by their earnings from work, for which health and physical strength are essential, that they support themselves and their families.

Many patients in our hospitals are children, but it is not merely for the sake of the enjoyment of childhood's games that they seek restoration to health. It is because they will have to face early the stern necessities of life in spheres of labour in which bodily soundness is of primary importance. The able-bodied worker, of whatever degree, should feel a bond of sympathy between himself and his fellow-worker laid by in the hospital, and should not be niggardly in his gift. Many, no doubt, now fail to contribute, not because they are not generous, but because the matter is not brought to their minds. They should not be allowed to forget.

These pages will be in the hands of many readers on the Sunday before the day upon which the Fund is actually collected, and they are urged in the interval to levy alms from all those who will not be present to give in person, and to bring them to the place of worship which they themselves attend.

An Appeal to the Young.

We have spoken of the vast population of London, of the importance that all should give, however small their offering, and of the part which those may play who remind others of the needs of the Fund. None can play the part of collectors better than can children, and none should bear greater goodwill towards the hospitals than the young. Most children know something of sickness and of pain. Their knowledge may be limited to the endurance of the ordinary ailments of childhood made as light for them as the loving care of parents in luxurious homes can make the necessary discomfort and confinement. On the other hand, they may in similar circumstances have borne real suffering. In any case they will be able to realise to some extent—for children have imaginations as well as their elders—what pain and suffering might be in "homes" where there is nothing that is worthy of the name, where there is no one to tend the sick with kindness, and where, in the crowded garret, there is neither food nor bed that can be faced without loathing and disgust. They will be able to realise to some

been there to see, w

injured children, when they are told that small boys and girls who have come in to be made well see themselves growing better with sorrow, knowing that to do so brings them nearer to the day when they must return "home."

The young can understand as well as their elders that to maintain the children's wards in our hospitals money is needed. They need not fear to contribute what may seem insignificant donations. If they give what they can, even though it causes them a little trouble and a little self-denial to do so, they can be sure that their help will be welcomed by those who most truly require it.

Conclusion.

In concluding our Appeal on behalf of the Metropolitan Hospital Sunday Fund for 1904 we would urge its claims upon all classes of givers for the same reasons upon which we have based our Appeal in the past; but we would lay stress upon the additional need for their generosity which is to be found each year in the ever-growing population of London, and in the increasing claims upon the hospitals from all parts of the United Kingdom.

The benevolent of all classes, of all religious creeds, and of all degrees of wealth, should give readily and generously to a Fund which is for the benefit of their poor and suffering brethren. These are relieved without regard to class or creed, solely on the ground that they are poor and suffering, and it is the universal duty to assist them.

The benevolent of all degrees of wealth, moreover, should remember that it is the skill and knowledge acquired and fostered in hospitals which come to their aid in time of need, and that the hospitals do not close their doors to them, whatever their wealth, when the street accident or other pressing cause requires that they should be tended without delay. The class which is succoured by the hospitals also should not forget them; very few, or comparatively few, are so poor that some pence cannot be spared in the course of the year as easily for a gift to the hospitals as for a pint of beer or an ounce of tobacco.

A special effort is being made in 1904 in order that the record of 1903 may be surpassed, and that the steady progress of the Fund may be maintained. None must be allowed to forget it who does not happen to attend public worship on that day when the collection is made. It is levied in many suburban churches and chapels, and in some districts more remote from London, but its extension to congregations who have not hitherto contributed is much needed. We showed in our Supplement last year that the London hospitals afford treatment to country patients to an extent varying from 7 to 30 per cent. of their total accommodation. This should afford a powerful argument to be used in many country pulpits.

To all we appeal for that exercise of self-denial which makes the gift a blessing to the giver. We appeal in the name of those who will never meet their benefactors to thank them face to face, but whose gratitude will be none the less real towards unknown friends who have helped them in their need.

THE METROPOLITAN HOSPITAL SUNDAY FUND.

Audited and found correct, this 23rd day of November, 1903.

(Signed) W. H. PANNELL & Co., *Chartered Accountants*, 13, Basinghall-street, E.C.

*** In the preparation of the voluminous statistics of hospital work which have been here digested and exhibited in collected form (and which have been specially supplied to us in response to our applications, and are quite independent of any returns made to the Metropolitan Hospital Sunday Fund Committee), we have been greatly indebted to a large number of secretaries and other officers of the various medical charities of the metropolis. To them we desire, as on many previous occasions, to tender our sincere thanks.—ED. L.

A Clinical Lecture

ON

THE EARLY DIAGNOSIS OF TUMOURS OF THE BLADDER.

Delivered at St. Bartholomew's Hospital on March 16th, 1904,

BY C. B. LOCKWOOD, F.R.C.S. ENG.,
SURGEON TO THE HOSPITAL.

GENTLEMEN,—I propose to speak to you to-day about the early diagnosis of tumours of the bladder and then if I have time I will proceed to their treatment. I have chosen this subject owing to the fact that tumours of the bladder are usually overlooked until they have got beyond the stage at which they are capable of being cured by surgery. This is very sad, because these tumours of the bladder, or the majority of them, when diagnosed early and accurately, are well fitted for surgical treatment. Tumours of the bladder, for our purpose, consist, first of all, of malignant tumours, of which this is one before you, and of innocent tumours, of which this is one. The malignant tumours of the bladder are comparable to the epitheliomata of the tongue which we discussed last week. You will remember the course which epithelioma pursued; first of all a growth, next degeneration and ulceration of that growth, and next bleeding, and next sepsis, and next infection of the neighbouring lymphatic glands, and ultimately of other organs of the body. In the bladder all these occur and with differences. For instance, there is a growth a little different from epitheliomatous growth of the tongue, because it projects so much more into the bladder. And as I suppose the person does not eat with his bladder, or talk with his bladder, or use false teeth in it so the growth has a better chance. Next, besides projecting more into the bladder and besides having a pedicle, as many of them have—and I shall have something to say about the stalk presently—these tumours are contained in a peculiar organ. First of all they are inside the bladder. I think you can make this generalisation about growths inside a muscular organ like the bladder and it is that they do not easily get out. For instance, epithelioma of the bladder is a very long time in making its way outside the bladder. Malignant growth of the gall-bladder is a long time getting out; malignant growth of the pylorus or of the stomach will go on for a long time. Malignant growths in the rectum and in the intestine usually are very long in duration; they go on much longer than you would expect, much longer than similar growths on the surface of the body, and that is because it is difficult to get through the muscular wall. There is perhaps another reason why growths inside the bladder do not easily get out of the bladder. Has the bladder got any lymphatics? I wonder what the answer to that question is. Sappey is very firm that the inside of the bladder has got no lymphatics. It must have very few if any at all. I believe the truth to be that the mucous membrane of the bladder either possesses no lymphatics at all or very few, that the muscular wall of the bladder possesses lymphatics, not in abundance, and that the peritoneal wall of the bladder possesses the usual quantity. The organ at the base of the bladder—the prostate—is well supplied with arteries, veins, and lymphatics, so that cancer of the prostate is a serious disease—a dreadful and rather rapid disease, I believe. Now, if I make this quite clear to you I would put to you another point, which is of very great importance with regard to these growths inside the bladder. You must all believe—you cannot help believing—that if a tumour has a pedicle that therefore it is innocent. Think of an ordinary polypus of the nose, of a pedunculated fibroid of the uterus; think of an ordinary fibroma of the skin and of other pedunculated growths. Innocency is a characteristic of pedunculated growths, but it is one which in the case of the bladder you cannot rely upon. A little piece of this growth has been removed, [illegible] put down in the museum [illegible] cent growth. I have had a [illegible] who said how beautifully [illegible] And I said to him that they had never had a section through the part which grew from the bladder. Without that the diagnosis is quite fallacious. The pedicle of bladder growths is a great trap: it leads you to think that malignant growths are innocent. You see it is such a nice shape, so easy to get hold of and to tie bits of elastic round, and to tie string round and to put clamps upon, and in the end the polypus has come away and the piece in the wall of the bladder has gone on growing. You have only taken away the piece which was sticking out and you have done it at great risk to the patient and have caused very much hæmorrhage and without the slightest benefit.

I would draw your attention to another thing and it is a principle in the surgery of malignant tumours—always avoid cutting the tumour; keep far away from its limits. You will all of you at some time or another attempt to remove tumours and growths. I will put on the board a diagram of a tumour of the wall of the bladder. I have made it have a sort of pedicle. Here is a vessel coming along the wall of the bladder to supply it. This vessel has thick walls. When it gets into the tumour its walls become thinner and thinner, until there is hardly a single layer of endothelium, having no muscular coat, no fibrous coat, but an endothelial lining. You can understand why, when the surgeon proceeds to tie things round that pedicle, when he proceeds to put elastic ligatures round it, or put clamps on it, he is dealing with a tissue which is rotten. There are vessels which cannot contract and which cannot retract and they pour out blood wholesale. No wonder the operation finishes with clamps on and yards of gauze in the bladder. The thinness of the blood-vessels explains a clinical characteristic which it is very important to understand. The bleeding generally takes place at the end of micturition. The reason for that is obvious enough. There is a very soft growth full of thin-walled blood-vessels. As the bladder contracts it squeezes the growth and squeezes some blood out of it. So micturition begins with clear urine but ends up with a spurt of bright blood. If the blood clots a little clot may be passed. This bleeding is not accompanied by pain in most cases. It is called spontaneous hæmorrhage into the bladder. What a beautiful word "spontaneous" is—how soothing! In the museum catalogue it says that this tumour was attended with no symptoms of importance except hæmaturia. Good gracious! If anything were more important to a human being and anything more terrifying to him it would be the occurrence of a little spontaneous hæmaturia at the end of the act of micturition. There is no pain. What I shall point out to you is that in any case of this sort steps ought to be taken to ascertain where that bleeding came from. In the early stages of the disease the steps can be taken without danger and they may end, as they are beginning to do now, in the cure of the patient.

I would now refer to the next event which happens after hæmorrhage: that ultimately the bladder and the tumour become septic. I do not know anything more serious than sepsis of the genito-urinary tract. The anterior part of the urethra, in front of the compressor urethræ, contains bacteria without doubt. But beyond the urethra and the bladder ought to be sterile and I suppose they are sterile in healthy people. These tumours usually become septic by the passage of instruments because the instrument is not passed with proper precautions. When a man takes a catheter in his hand to pass it upon another human being he ought to consider that he is performing an operation which is about equivalent in danger to amputation of the leg. The septic material put in may not make its presence apparent at first but once placed in the bladder and in the urethra it sets up a long train of dreadful events and the sepsis affects other regions of the body. I will tell you a story which may impress that upon your minds. A man had upon his body a series of abscesses in his cellular tissue. The abscesses were supposed to be tuberculous and they were opened and treated. Some of them healed but usually a little sinus was left. On his cheek he had another swelling which happened to be a dermoid cyst and was mistaken for one of these abscesses. After a year or 18 months' treatment for tubercle—he was supposed to have his lungs affected with tubercle also—his case was investigated. It was obvious that he had some form of chronic pyæmia and that he must have some source of infection in order to get the continuous formation of abscesses over a period of 18 months or two years. It was most difficult to find the source of infection but at last he was requested to pass his urine into a glass—not into one of those mediæval pewter dishes such as are used at our hospital. The urine should always be passed into a proper clean glass beaker. It was then found that the urine was full of shreds of lymph. Inquiry showed that he had a stricture and that he had a septic genito-urinary tract. It was necessary to disinfect the bladder and urethra and to do that it was essential that the stricture should be operated upon; that was done and afterwards the bladder was washed out with nitrate of silver and the source of infection cut off. After that he never formed another abscess but became well. Sometimes the source of infection is exceedingly difficult to trace. I remember seeing a woman with arthritis and on inquiry it was found that she had septic endometritis and when that was cured she had no more attacks of arthritis. So when you see a person with so-called subacute rheumatism of the knee hunt about and you will find an infection in some part of the body. This sepsis started in the bladder may after a while—it takes months or years—pass up the ureters and infect the hilum of the kidney, and afterwards it affects the kidney itself and then you get a form of septic nephritis started. It is painful to think that it starts the sort of nephritis which is called surgical kidney in the older books. I suppose that is because it was thought that no surgeon could ever look at a patient without giving him sepsis of the genito urinary tract and septic kidney. Here is one of the kidneys put for you to see. I will tell you something else about the sepsis in these cases which has a most dreadful effect upon the mortality from operations. Operation, when it is performed even under unfavourable conditions but on patients whose urine is acid, is attended with a small relative mortality. For instance, at this hospital—the statistics are improving—16 patients had a single tumour of the bladder removed. The condition of the urine was known in 14. It was slightly septic in two and acid in 12. You must not assume that I think that because the urine is acid therefore it does not contain any form of infection. You are aware that acid urine very often contains the colon bacillus, but not a very virulent form of sepsis, one which does not affect the mortality in a high degree. Of the 12 with acid urine three died—that is to say, a quarter of them. The two with slightly septic urine recovered. Of those who died with acid urine one died from hæmorrhage, another from shock, and another from pyæmia. So the probabilities are that only one of the people with acid urine died from a septic disease. If we take the people who were operated upon and had septic urine there were ten operated upon and five died, one of them from septic peritonitis, one from septic cystitis, and another from cellulitis due to extravasation of septic urine; two were not examined after death. Thus the mortality had risen to 50 per cent. That is a very dreadful proportion. There is another reason why you should not delay in these cases. If you delay the case is sure to become septic and the mortality is, owing to that fact, sure to be enormously increased. There is another reason why you should not delay. It is that after a while the tumour grows to such an extent that at last it becomes an inoperable case. Here is a tumour of the bladder which may or may not have been operable, but I doubt if it could have been removed without some part of the ureters and perhaps going beyond the wall of the bladder. But on looking at it closer I see that it has already got outside the wall of the bladder, which makes it inoperable.

I have spoken so far about malignant tumours of the bladder. There is another class of tumour of the bladder which you may see here, in which the whole bladder becomes full of shaggy growth It occurs in younger people than those who have malignant disease—that is to say in men and women below middle age These patients suffer very little pain, they have constant hæmorrhages, they do not suffer at first very much in general health, and the disease *goes on for* a very long time. That is a horrid disease I have seen a man operated upon for that disease for the ninth time. I cannot imagine what will cure that particular kind of disease. The only operation which I should imagine would cure it would be to remove the whole mucous membrane of the bladder, which is not a particularly feasible form of operation, and it probably has not been done in this country. The whole bladder has been removed both in this country and abroad at various times. I think that there is some application which might be made to those tumours. I have reason to know something about one of these cases which was treated with a strong solution of perchloride of iron and which had a very long interval of repose, the bleeding ceasing for some years. I have told you about the diagnosis resting on first the pain and then the spontaneous quiet hæmorrhage at the end of micturition, and I shall now tell you something else about the hæmorrhage. It is a thing which may mislead you very much unless it is perfectly clear in your minds—and it is that the hæmorrhage is most irregular. A person will bleed and then have a latent period of perhaps a year or 18 months and then bleed again and then have another interval. But the intervals become shorter and shorter until at last the patient bleeds with every act of micturition. And by that time the case is probably hopeless. In truth, these tumours of the bladder behave in a most extraordinary manner. I remember once looking into a bladder with the endoscope and seeing a flat epithelioma of about the size of a florin near the neck of the bladder. For some reason the man was not operated upon, but he was afterwards explored by Mr. H. T. Butlin, who saw the growth with the naked eye and felt its hard base—and epitheliomata have a hard base. Nothing could be done; it could not be removed because it was beyond removal at that stage, and he went home. I remember seeing his medical attendant who was a patient of mine. He said, "You made a nice mistake about that tumour of the bladder." I said, "Why do you say that?" He answered, "Because the man is perfectly well; he is walking about and has returned to his duties as a police constable. You are all wrong about it. Besides, when I wrote and told Mr. Butlin he said he had made a mistake." Probably Mr. Butlin did not recall all the circumstances. I said, "I cannot tell you what other people may think, but that man has got epithelioma of the bladder, and in a little while the man will have a horrible hæmorrhage and die from it." He went on with his duty for two or three months, apparently perfectly well, thinking he was cured. Then he had a violent hæmorrhage and died. So you must have clearly in your mind that the cessation of hæmorrhage in a case of tumour of the bladder means precious little.

Another thing which may be talked of as a matter of diagnosis is the passage of pieces of growth. They are very fallacious. I have seen a bladder opened twice to find a growth which did not exist, although those pieces of tumour had been seen by skilled pathologists under the microscope. The bladder was opened by two different surgeons. One surgeon opened it, having seen the villous growths, and another was so sure there were villous growths and that the other surgeon had overlooked them that he opened the bladder again but could find none. Of course the bits may have passed down the ureter from the hilum or the kidney. So I attach importance to seeing villous growths but not much. Remember, it does not tell very much about the actual character of the growth; the stalk and not the villi determine that. I remarked last time that epitheliomata of the tongue were exceedingly painful. That does not by any means apply to the bladder. It is true that an analysis of the clinical notes of this hospital show that pain is present in three-fourths of the cases in some part of the body; the remaining fourth seem to be free from pain. So it is not a diagnostic sign which will afford you very much assistance.

I shall now come to another point which may assist you. It must be clear to your minds that, given a tumour of the bladder, its clinical characters of necessity are doubtful. The greater includes the less if you assume that all tumours of the bladder are malignant. The statistics of this hospital show that the proportion of malignant to innocent tumours is 4 to 1. Albarran, who microscoped, I think, 84 tumours of the bladder and did them very thoroughly, made out a proportion of five malignant to one innocent, so that the proportion is exceedingly high It is far safer to assume that a given tumour of the bladder is or will become malignant than to assume that it is innocent. Supposing we make up our minds that a person has a tumour of the bladder, there are certain things which will lead you to suppose that it is not operable. I need hardly now go over them all because they pertain to malignant disease in any part of the body. But one thing which makes you very chary of performing the operation is the presence of sepsis, because you make a determined effort before, at, and after the operation to disinfect the bladder. But another thing which would lead you to suppose that a case was inoperable would be that you could feel the growth I believe that is a very significant sign. If, for instance, a patient is known to have tumour of the bladder and you can feel it above the pubes or per rectum or per vaginam I think it is an inoperable case. I might operate on such a case if I were pressed but I think it is better not to operate upon those cases. I shall come directly to the question of diagnosis of these cases, but there is another thing which surely renders the case inoperable, and that is if you cannot by means of the endoscope see the whole extent of the growth. If by means of that instrument you cannot accurately discover its limits the probabilities are that it is not a case to which you can do any good by operation. Of course, if you felt the growth outside the bladder and that it was fixed obviously nothing could be done.

Now, as regards the actual diagnosis of these cases the diagnosis of a tumour of the bladder in its early stages is one of the simplest and easiest feats in surgery. You may have seen the endoscope frequently used and therefore I need not dwell long upon it. But there are one or two things which should make you careful as to what you promise a person from an endoscopic examination. I think an anæsthetic is necessary. I am aware that surgeons use the endoscope without an anæsthetic but for a variety of reasons I think it is far better to give the patient an anæsthetic; the parts are quiet and you can conduct the observation in a leisurely and thorough manner. Supposing you have a patient anæsthetised the next matter is the extreme importance of not introducing sepsis at the time of examination. We are in the habit now of preparing the field of operation exactly as we should for any other operation on the genito-urinary tract; the pubes is shaved, washing is done, and all the organs of generation are thoroughly disinfected, and the surgeon's hands also. One endeavours, as far as possible, to do an aseptic operation. I think I have made it clear to you how extremely important asepsis is in these cases. Having got the field of operation clear and an endoscope ready you have to prepare the bladder for its introduction, and that is a most troublesome proceeding. One of the great enemies is the presence of blood or pus. Pus you can wash out but blood is more difficult because it re-forms quickly. We have tried all sorts of things. One of the great ways to prevent hæmorrhage is to keep the patient quiet before the examination, to take care that there is no rough handling or shaking about at the time of examination, and, in the next place, to pass all your instruments with infinite gentleness and care. But supposing the bleeding continued, we have sometimes found that we could stop it and get the bladder sufficiently clear of blood for a time by injecting a 1 per cent. solution of hamamelis. It is necessary to get the clear solution. The other day we managed to see into a very difficult bladder indeed by putting into it some solution of adrenalin. That had a very marked effect upon the hæmorrhage and for a time we clearly saw a villous tumour of the bladder, but we never saw its extent. I thought it fair and right to give the man the chance of operation. I thought I should not infect him or make him very much worse and so his bladder was operated upon; but I could not undertake to relieve him altogether and to remove all his papilloma and he is in Kenton Ward now with, it is to be feared, a considerable quantity of papilloma still in his bladder. I am cudgelling my brains for some way of improving that man and getting rid of his papilloma, whether by perchloride of iron or by the cautery or by amputation I do not yet know. I have made up my mind to try again.[1]

Supposing a papilloma has been correctly seen and its position ascertained I think you should proceed forthwith to perform the operation. The operation ought to have this essential feature: you should see what you are doing. You may think that that is a very small point, but if you look into the literature of this you will find people have often performed this operation and not seen what they were doing. One surgeon performed it through the perineal route. Not only was his mortality high but the tumours went on growing just the same as before. At this hospital a number of times a tumour has been removed through the female urethra. A nice little papilloma with a beautiful stalk is seen in the bladder and then something is poked up the urethra and it is pulled off. Of course, this leaves its growing base. So you can understand that removal of these pieces through the female urethra has not done the patients very much good. I am speaking from memory but I think five out of six were known to have returned. So the matter of seeing what one is doing is a very important one in this respect and it is not a matter which only affects epithelioma of the bladder; it is a principle in surgery that you should see what you are doing and there are very few cases in which that does not hold good. Sometimes in the abdomen when there is a moveable organ like the vermiform appendix the surgeon feels the appendix and withdraws it through the wound and it is removed. That part is seen but the other parts are not. But the moment any question arises the wound should be enlarged and the rest of the operation carried out guided by the most clear vision. There is another point about the removal of these tumours of the bladder. Of course, if you see what you are doing you must do the operation above the pubes. Another point which is important about them is, I do not think you will succeed unless you use an electrical head lamp. This requires a little practice for its use, but I think it is absolutely essential for the purpose of these operations. When the bladder is freely opened it is useful to see what sort of tumour you have got by putting in a speculum. It is a convenient thing to put in. The bladder is dried with sponges and you then see the limits of the growth. One of the difficulties about operating on the bladder is the retraction of the edges of the wound, which is the next step after removal of the speculum. I think proper retraction is best done with silk through the whole of the bladder and abdominal wall. An assistant uses the silk as a retractor and it also prevents the operator pushing the bladder back into the pelvis and opening up the cellular tissue more than is needful. Supposing you have made up your mind you will remove the tumour, you may have already guessed that I have a strong impression as to the manner in which it should be removed. It should be removed like any other malignant tumour, say such as one of the mammary gland, with a wide margin of sound healthy tissue round it. Fortunately, this is not difficult in the case of the bladder, because when you come to think about the bladder you will remember that except at the trigone the mucous membrane of it is exceedingly loose. Again, let me remind you that the mucous lining of all the distensible organs is very loose, such as the stomach, the gall-bladder, and the intestines, and so it is not difficult to take hold of that mucous membrane and draw out a piece of it towards the wound. You know how these tumours bleed and I think they do so because the surgeon meddles with the malignant growth. If he will be very careful he will find that he can get on with his operation and have very little bleeding. A piece of catgut is threaded through the wall of the bladder at some distance—say, three-quarters of an inch—above the papilloma. That serves to pull the mucous membrane of the bladder and the papilloma towards the wound. Next, a cut is made through the healthy mucous membrane along each side of the stalk. It is best to keep suturing this cut as it is made and to keep the ends of the sutures to hold on by and steady the bladder with. Last year a very fat old man was in Pitcairn Ward. I should think he had about three inches of fat upon his abdomen. An enormous incision had to be made to get into his bladder. When the bladder was exposed and the peritoneum and fat pulled up, by enlarging the incision one could get at the papilloma, which was not very far from the base of his bladder. I looked into his bladder and I saw what I had been looking for—a vessel to feed the tumour. Catgut was put under that and the blood-supply cut off from the tumour, and everyone was surprised to see a big papilloma removed with certainly no hæmorrhage of any consequence. If you have failed to tie your vessel you will meet with vessels in the incision, but if you are far enough from the tumour you will meet with the vessels where they have got proper walls so that you can take hold of them and tie them. As your incision proceeds you can close it with catgut as you go along. Make half-an-inch incision and close it with catgut suture then make another half-inch incision and close that. Finally, you have got the pedicle of the tumour out surrounded by healthy mucous membrane.

Next with regard to what you shall do with the bladder itself. I allow the decision on that question at the end of the operation to turn upon two conditions. One is, Is there any oozing of blood proceeding; and the other is, Is there any sepsis? I should put the sepsis first in importance. If the bladder is septic you had better proceed on the ordinary rule of surgery which is that septic cavities should be drained. It is a safe rule, I think. So you close the wound in the bladder and in the abdominal wall with fishing-gut or silk sutures and you will drain it. And I would draw your attention to what, as far as I know, is the best drainage-tube to use. This is a Guyon's drainage-tube and it is very nicely made with a proper curve to go into the wound and into the bladder. It has a rounded eye and a notch at the base so that the urine cannot be easily stopped. It is a double tube and you can wash through from one into the other. In addition, you can always get it to syphon out. It ought to syphon out anything which is contained in the bladder. You put the short stem into the bladder and the long stem over the side of the bed into some vessel and have it syphon into carbolic lotion. This particular drainage-tube has deprived the operation of very many of its terrors. Altogether it is a device of very great service.

---

[1] Since explored. The papilloma was small and easily removed. The man seems quite well.

Now let us take the other case in which you close the bladder. If you have removed the small papilloma and the wound in the bladder wall has been closed, and supposing that the bladder interior is not septic, it is safe to close the bladder forthwith. And the way one does that is as follows. A fishing-gut suture is passed through the skin, through the abdominal muscles, through the muscular layer of the bladder wall, and up through the opposite side and tied, and that brings the bladder and mucosa close together. In the absence of sepsis this succeeds exceedingly well. We have had three cases in which it has been safe to close the bladder wound immediately in that manner, and I believe I am correct in saying that each of the three patients was walking about the ward at the end of three weeks. And that is of great advantage, because if a drainage-tube is put in it will be from six weeks to two months before the patient will be able to get about properly. With regard to the subsequent history of these cases of bladder growth, when done in this particular way I believe the outlook is favourable, but as yet not many have been done freely and thoroughly. When done in the ancient way of tying bits of string or rubber round the pedicle or by clamps put round the pedicle the operation is futile, and if I had the misfortune to have an epitheliomatous tumour of the bladder I would decline to have such a proceeding performed upon me.

In conclusion, I will say this to you: everybody here ought to practise using endoscopes and all the other scopes. If a man can use the ophthalmoscope properly he will soon be able to use the endoscope and otoscope, and these instruments have been enormously improved of late. This endoscope which I show you has got a lamp which does not produce heat, it keeps quite cool, it has got an apparatus for catheterisation of the ureter, and also an arrangement for putting some additional fluid into the bladder. It is also useful if you want to distend the bladder a little more or to withdraw some of the fluid or if you want to see how much blood there is, and in fact it is a highly convenient instrument, and it is also better arranged than the ordinary run for disinfection. There is no gentleman here who could not if he chose to practise with it soon become expert in its use.

The Lumleian Lectures

ON

SOME DISORDERS OF THE SPLEEN.

Delivered before the Royal College of Physicians of London on March 17th, 22nd, and 24th,

By FREDERICK TAYLOR, M.D.,
F.R.C.P. LOND.,
SENIOR PHYSICIAN TO, AND LECTURER ON MEDICINE AT, GUY'S HOSPITAL.

LECTURE III.[1]

Delivered on March 24th.

ANÆMIA PSEUDO-LEUKÆMICA INFANTUM.

MR. PRESIDENT AND GENTLEMEN,—By the above cumbersome and almost meaningless name von Jaksch described in 1890 cases of enlarged spleen in infants in which he recognised that with a certain amount of leucocytosis there was an absence of the complete picture of leukæmia or leucocythæmia. He said that there were oligocythæmia, oligochromæmia, persistent leucocytosis, enlargement of the spleen, slight swelling of the liver, and sometimes swelling of the glands. He noted the following points of difference between leukæmia and anæmia pseudo-leukæmica infantum—namely, in the former the presence of eosinophiles which were commonly absent from the blood of his infantile complaint; in the former the loss of corpuscles and of hæmoglobin was never so great as in the latter; in the former, leukæmia, the liver was much larger relatively than ever it was in the latter. In the latter (his splenic anæmia) the prognosis was much better. The following points he mentioned as distinguishing rickety enlargement of the spleen from an anæmia splenica pseudo-leukæmica—namely, in the former a lower grade of leucocytosis, a slower progress of the changes, and other conditions typical of rickets.

Some reference may be made to more recent work bearing upon this subject. Dr. Samuel West at the meeting of British Medical Association in 1900 read before the section of Diseases of Children a paper on Enlargement of the Spleen in Children and he there paid particular attention to the splenic anæmia of the infant. This subject was treated without any specific reference to von Jaksch's pseudoleukæmic form, and he stated that the blood showed no changes but those of simple anæmia. At the same time he was expressly not referring to cases of splenic anæmia which could be classed with those of the adult—such cases he stated were extremely rare in children. He was obviously describing the cases with which we are all so familiar and have so long associated with rickets, of moderate but sometimes great enlargement of the spleen with anæmia in young infants. He pointed to the waxy ivory-like colour of the skin with a tinge of olive-green, to the large spleen, to the digestive disturbances, the appetite capricious or bad, or, on the other hand, excessive, to the occasional hæmorrhages, the enlargement of the liver in about half the cases, and the occasional occurrence of pyrexia. He noted the frequency of rickets and syphilis as accompanying or causative conditions and agreed with some other writers as to the generally favourable prognosis. His account of the blood is to the effect that the erythrocytes are reduced it may be to 40 per cent., that the hæmoglobin is reduced in the same proportion (or according to some authors in greater proportion), that nucleated red cells and myelocytes are present, that the only leucocytosis is one affecting the lymphocytes, and that this is in direct relation to pyrexia. Histologically the spleen is in a condition of hyperplasia, with slight fibrosis. Though recognising the frequent antecedence of syphilis and still more of rickets in these cases of anæmia he doubts if they are the sole cause, and they may be causative only by means of the ill-health which each produces. The relation of the spleen to the anæmia has to be determined. He thinks that the different histology of the spleen in adult and in infantile splenic anæmia shows that the spleen cannot equally cause the anæmia in both. He inclines to the view that there is a common cause for the splenomegaly and the anæmia, which he allowed might be a chemical toxin from the intestine. Dr. A. M. Gossage in the discussion mentioned a case in which there was leucocytosis to the extent of 30,000 per cubic millimetre, with increase of eosinophiles as well as lymphocytes, and the presence of a few myelocytes. It will be seen that this case at least accords with other observations on the condition of the blood.

Two years later, again at a meeting of the British Medical Association, the subject was discussed by Dr. J. S. Fowler of Edinburgh. He expressed the view that splenic pseudoleukæmic anæmia was a special form of disease distinguished by its blood characters. There are red blood corpuscles numbering from 1,500,000 to 3,000,000 per cubic millimetre, a low colour index, the presence of normoblasts and especially megaloblasts in considerable numbers, a moderate leucocytosis of from 10,000 to 30,000 per cubic millimetre in which the lymphocytes rather than the polymorphonuclears were increased, and of the lymphocytes large hyaline and transitional forms rather than the small lymphocytes, and the presence of a small number (from 0·2 to 6 per cent.) of myelocytes. He gathers little from the histology of the spleen or liver in three fatal cases: one spleen was congested with distinct Malpighian corpuscles, another was anæmic with indistinct Malpighian corpuscles. But he says the spleen may be of very great size is always an essential factor, and commonly the anæmia is severe in proportion to the size of the spleen. He would discriminate between this and the rare case of a *spleno-medullary leukæmia occurring* in an infant (myelæmia). As to causation, this remains obscure, but he thinks *that* rickets although common is not essential and that the enlargement of the spleen probably always precedes the anæmia and is in some way responsible for it. He admits, of course, differences in degrees of severity or intensity of the various symptoms, but thinks that they are all one and the same disease and, as stated in the early part of his communication, that all these cases of simple enlargement of the spleen in young infants arising independently of any necessary antecedent disease, unless it be rickets, belong to one clinical group. On the same occasion Dr. C. H. Melland of Manchester recorded eight cases of splenic anæmia of infants. The blood counts of these cases agreed very closely with those of Dr. Fowler and the cases in general seemed to be identical in all their characteristics. Dr. Melland called attention to some differences between the blood of infants and adults and showed that some of the characteristics in these cases had a less serious significance than they would have in adults. He contended that the cases formed a definite group of splenic anæmia and that they were not merely the extreme forms of the secondary anæmia of rickets and malnutrition, as urged by Wentworth in the *Boston Medical and Surgical Journal* for October, 1901.

---

[1] Lectures I and II. were published in THE LANCET of May 28th (p. 1477) and June 4th, 1904 (p. 1554), respectively.

Some quite recent work on this subject may be within your recollection. I refer to two papers which have been read before the Royal Medical and Chirurgical Society, one in November last by Dr. Clive Riviere, and the other only last month by Dr. J. H. Drysdale and Dr. J. H. Thursfield. Dr. Riviere's account of the disease based on 13 cases differs in no material point from that which has already been noted —the large spleen, the association with rickets and syphilis, the oligocythæmia, the low colour index, the presence of normoblasts and megaloblasts, the moderate leucocytosis with prevalence of lymphocytes, and the occurrence of a small percentage of myelocytes. But his contention as to the nature of the disease is not that it is a peculiar form of anæmia in the infant but practically the only one. He says: "Is there any other form of marked anæmia recognisable in infancy? The answer I should make to that is, No, I have never seen it, have never found a description of such, and see no reason at present to believe in its existence." In his opinion cases of anæmia, spontaneously occurring, which do not present all the typical features described, are cases in an early stage of development; when they become severe they are typical. The prime factor is gastro-enteric catarrh and this is invariably due to bad feeding. In association with the gastro-enteric catarrh poisons are absorbed from the intestine, such poisons being either (1) the result of organisms, as e g., the organism of summer diarrhœa; or (2) the by-products of disordered digestion. These poisons will wash into the blood lymphocytes from the irritated lymph glands; the poisons will reach and stimulate the bone marrow; leucocytosis takes place for a time with increase of polymorphonuclears and eosinophiles, but the leucocytosis failing, the demand can only be partially kept up by particularly formed granular cells, myelocytes, which now appear in the blood. Again, failing leucocytosis, the destruction of the red cells takes place and the characteristic oligocythæmia occurs. By a reference to von Jaksch's originally published cases and the few cases recorded as leukæmia splenica in infants he tries to show that there is no important difference between them and the cases he has investigated. I think the latter half of his task is more difficult than the former but I am not at present here concerned to consider whether or how often a true splenic or spleno medullary leukæmia occurs in infants—obviously rarely—and Dr. Riviere thinks that even the condition of histology of the spleen may only be an extreme development of infantile splenic anæmia and that cases will be found bridging the gap, presumably both in respect of the extent of the myelæmic leucocytosis and in the histology of the spleen. His speculations on the nature of the poison, his belief that it is not one specific toxin but may be one of many, and his suggestion of a resemblance to the bacteriological conditions of pneumonia and broncho-pneumonia are extremely interesting and suggestive. Dr. Drysdale and Dr. Thursfield come to a different conclusion. They record 23 cases, of which the general conditions and the state of the blood were identical with those given by other authorities, so that there can be no doubt they are dealing with the same complaint. Their contention, however, is that it is a disease *sui generis* that is not due to rickets or to syphilis, that the differences between it and leukæmia proper are very considerable and presumably too great to be bridged over. They allude to the fact that some authors regard any other anæmia occurring in infancy as a possible early stage of this disease, and return answer that none of the ordinary causes of infantile anæmia were noted in the history of the majority of their cases. In support of their views they also give blood-counts from cases of rickets, infantile scurvy, and syphilis, which show marked differences in the various points with regard to which infantile splenic anæmia is supposed to be peculiar.

Comparing the views of these six authors we see that the main difference of opinion is as to whether von Jaksch's infantile splenic anæmia is a separate entity or not. Dr. Fowler, Dr. Melland, and Dr. Drysdale and Dr. Thursfield think it is, Dr. Riviere thinks it certainly is not, and Dr. West has at least not specified its separate existence. It is expressly or tacitly observed that the histology of the spleen affords no help on this point, though it is of importance as distinguishing the infantile form from adult splenic anæmia and from the leukæmic spleen. So far as the latter is concerned Dr. Riviere is prepared to see that distinction abolished. In regard to the former, some points in the history of a case mentioned at my last lecture are of interest. It is the boy who suffered simultaneously with his sister from splenic anæmia. The first record of his illness is when he was four years old, but it is stated that he had always been sickly and did not walk till 18 months old. From his birth he was subject every two or three months to severe attacks of diarrhœa, often with slime. Now it is conceivable that this boy was as an infant the subject of splenic anæmia of von Jaksch's type. On two or three occasions when older a leucocytosis is recorded; and most interesting of all, in 1900, two years before his death, his blood contained a small number of myelocytes, as did that of his sister about the same time.

The fact that rickets, syphilis, and an unknown factor produce forms of anæmia with splenomegaly which are so closely alike (and according to one author are identical), the fact that an adult splenic anæmia can be produced by syphilis as shown by Dr. S. Coupland's well-known case, the improvement brought about by mercurial treatment in infantile syphilis and splenomegaly as stated by Dr. A. E. Russell, the recovery of a certain proportion of the cases (whether von Jaksch's cases or not) on what may be called rational lines of treatment, suggests a resemblance between syphilis and rickets and the unknown factor as causes—in other words, supports the view that a toxin of some sort is the cause.

The pathology of rickets must be admitted to be sufficiently obscure and in the rickety cases it would still remain open to question whether the toxin producing the anæmia and splenomegaly is still the cause of the rickets or whether the defective formation of bone is a mere matter of chemical metabolism, and the toxins are independently produced and independently operating. That the early symptoms of rickets include a general constitutional disturbance, with general tenderness and sweating at night and sensation of heat or oppression, is as readily explained by the existence of a toxin as by anything we know of the relation between fat and proteid starvation on the one hand and defective bone-formation on the other.

I do not wish by these observations to let it be understood that I am accepting without reserve the identity of the infantile anæmias, as Dr. Riviere would have it. I only suggest that there may be identity in procedure—namely, by means of toxins—even though there is difference in detail, that is, in the nature of the toxin. That if, as is surmised, an intestinal toxin is the cause of von Jaksch's variety, and if the syphilitic toxin can cause anæmia of its own, still more, if it can do it by raising an intestinal toxin, then the other cases of splenomegaly and anæmia, whether rachitic or of other source, are most likely due to a similar agent. Granting that they are all anæmic, that all have enlarged spleens, that they are all in infants, on what does the distinction depend? A certain number of the rather severer cases have some differences in their blood composition, which consists of a pronounced oligocythæmia (a mere matter of degree), a variable leucocytosis—never very great, an excess of lymphocytes, and a few myelocytes. In the face of the fact that both these last conditions are common to infants—a fact made much of by Dr. Riviere but at least allowed by Dr. Melland—it seems a rather unsafe criterion upon which to found a separation. Moreover, this distinctive lymphomyelæmic condition is, as far as I can see, not associated constantly with any other difference and therefore it cannot be regarded so far as specific. It may be only a matter of severity or duration or degree.

Dr. Gemma[2] records two cases of infantile splenic anæmia presenting the familiar characteristics both as to the blood and to the spleen. In one of these cases he isolated the bacterium coli commune from the splenic blood obtained during life. He admits, however, that if it is an infective disease more than one organism might produce it and discusses its relation to rickets, which he regards as probably infective, to intestinal toxins, and to syphilis.

HODGKIN'S DISEASE.

The spleen in Hodgkin's disease takes a subordinate position; it is so obviously not the starting point of the disease. It is rarely of very great size and the deposits of lymphoid tissue which form one of its characteristics are not universally present. I have brief notes of 21 cases which have occurred in the period of ten years formerly specified. I am afraid there is not much that can be gathered from this set of cases which adds anything to our knowledge. They are cases mostly of several months' duration, with rather a striking predominance of males over females—namely, 19 males to two females. The period of youth is also more productive of the disease than that of middle life or old age. Of the 19 in which the age is given seven were under 20 years of age, four were under 25 years, and only five were over 40 years of age, and the average age of the 19 cases is 30 years. The weights of the spleen of the cases examined post mortem were respectively three, five, seven, 13, 16, 22, 29, 30, and 65 ounces. Of others of which no post-mortem examination was obtained there were four in which the spleen appeared to be normal, two in which it was palpable, three others respectively two inches below the costal margin, three inches below, and reaching the umbilicus, while in one case the spleen probably reached a very large size. I say probably because the splenic nature of the abdominal tumour in this case was questioned by more than one of my colleagues and no opportunity of determining the truth by post-mortem inspection occurred. But for the belief that the patient suffered from Hodgkin's disease I think there are strong grounds. After a blow on the neck some of the left cervical glands increased in size and persisted. After 12 months they were excised and at this time there was no evidence of an enlarged spleen or of any abdominal tumour. Five months later there was a large mass in the abdomen, occupying the left side, reaching down below the umbilicus and crossing the middle line.

This persisted for eight months under occasional observation. The patient had moderate oligocythæmia, no leucocytosis, but remittent pyrexia of the kind which has been seen in connexion with Hodgkin's disease. She died outside the hospital a year later than the last observation.

There are two questions with regard to lymphadenoma or Hodgkin's disease to which these cases may help in supplying the answer. One is its relation to tubercle and the other its relation to lymphatic leucocythæmia. I do not think the existence of the latter relation is generally allowed at the present time. The fact of leukæmia is regarded as shutting off a certain class of cases, and the very fact that lymphadenoma or Hodgkin's disease is called by German pathologists pseudo-leukæmia represents the conviction that the two conditions—Hodgkin's disease and lymphatic leukæmia—are different diseases. The independence of the two complaints is supported by these cases, for of the 14 in which the leucocytal condition is specified either there was no leucocytosis (five cases), or it was exceedingly slight, not more than 12 000 (four cases). or if it was sometimes noted as 30,000, 40,000, or 50,000 the polymorphonuclear leucocytes were greatly in excess of the uninuclear, and hence neither of the forms of lymphatic or splenic leukæmia was assumed. But a case, which I shall say more of later, was regarded as Hodgkin's disease on the strength of a blood count showing 6250 leucocytes, yet quickly developed lymphæmia. Dr. Wende[3] publishes a case bearing on this; lymphomatous growths appeared in the skin and the glands were enlarged, five months later the leucocyte count was normal, three months after that lymphæmia intervened, and three weeks later death occurred. This he regarded as a conversion of Hodgkin's disease into leukæmia.

The other question is of more recent origin. The clinical difficulty of distinguishing the glandular hyperplasia of lymphadenoma from that of tubercle must be admitted; the occasional occurrence of caseation of some of the glands and the coexistence even of miliary tuberculosis must also be admitted; but the view that the hyperplasia of the glands and spleen in Hodgkin's disease (apart from the familiar appearance of grey tubercle or caseation) and the peculiar growth of lymphoid nodules in the solid organs are the results of infection with the tubercle bacillus appears to assign entirely new powers to that organism. Out of the 12 cases which (with some reserve as to two cases which may have been sarcoma or lymphosarcoma) may be regarded as lymphadenomata in only two was there any appearance of tubercle. In one there were minute caseating points in some cervical glands and early caseation in some of the lymphoid tumours of the spleen. In the other two mesenteric glands out of many showed a caseating tuberculous deposit.

LEUCOCYTHÆMIA.

It is perhaps about leucocythæmia or leukæmia that more interest has been shown than in almost any disease of the spleen, doubtless because it was the first in modern times in which it appeared clear that the spleen was directly and primarily responsible for a serious and fatal disease. For though the ancients regarded the spleen as capable of causing palpitation either by enlargement pressing upon the heart or by the passage of melancholic vapours from it to the heart, and though Aretæus thought that jaundice might result from disease of the spleen (and, indeed, other organs) as well as of the liver—the jaundice then being of mixed black and green colour because it was the function of the spleen to cleanse the black blood—in more modern times the diseases of the spleen were more obviously secondary either to heart disease and cirrhosis or to the infection of malaria and some other febrile complaints. Time does not allow me to go into the history of the first discovery of leucocythæmia, almost simultaneously as it was by Professor Hughes Bennett of Edinburgh and by Professor Virchow in Germany; but there has been a considerable advance in our knowledge since that time, very largely in consequence of the deeper acquaintance with the histology and pathology of the blood, which has been possible with increased powers of the microscope and improved methods of colour-staining.

To even a greater extent than in splenic anæmia and anæmia infantum is the condition of the spleen associated with that of the blood, and the division is now universally recognised into a lymphatic leukæmia or lymphæmia and a spleno-medullary leukæmia or myelæmia. In the former the leucocytal increase is characterised by the extraordinary predominance of lymphocytes, which may be 90 to 95 per cent. of the whole number of leucocytes; in the latter the polymorphonuclear leucocytes and the form of cell known as myelocytes correspond to between 80 and 90 per cent. of the whole, themselves in about equal proportions. The spleen is, as a rule, enlarged in both of these forms, but the amount of enlargement is strikingly different. In the spleno-medullary form, as is well known, the spleen reaches often a greater size than it does in any other disease, whereas in lymphæmia or lymphatic leukæmia the organ is relatively but little involved or undergoes only a slight enlargement. I find in the records of Guy's Hospital over the period already specified (Post-mortem Examinations 1892–1901, Clinical Reports 1897–1901) 29 cases which have been regarded as possibly cases of the kind. Of these, 16 are unequivocally spleno-medullary leukæmia, four are cases of lymphæmia, one appears to be a mixed form, and eight are doubtful. Of these, one was probably splenic anæmia, another pernicious anæmia, two others were extensively tuberculous, though in one of these the spleen weighed 49 ounces. In the last four cases the history and details of the blood examination are insufficient and one of these patients was alive five years later. Time, again, does not allow nor would it serve, I think, much useful purpose to give details or even brief notes of all these. In respect of the cases of spleno-medullary leukæmia there is little in them that differs from what has been long known with regard to this form of disease. In the later cases the diagnosis has always been confirmed by the blood counts showing the presence of myelocytes in the usual proportions.

The striking feature of this form of disease is the great size of the spleen. I have arranged here on the screen the diagrammatic representations of the spleens (and livers) in the 16 cases of the spleno-medullary form, and the weights in ounces in those cases of which a post-mortem examination was made are given. These ten spleens vary in weight between 48 ounces and 128 ounces (from 3 pounds to 8 pounds) with an average of 91 ounces. The actual weights are in ounces: 128, 128, 112, 110, 104, 84, 77, 61, 57, and 48.

[3] American Journal of the Medical Sciences, December, 1901.

Another remarkable fact which must have some connexion with the pathogeny of the disease is that the disease is so rarely seen in its early stages; the spleen is rarely seen to grow to the great size it attains, but already when the disease is discovered the spleen is of great size, or the illness is revealed only because the spleen is painful or causes dragging pain in the side and not because of any general malaise or anæmia. If, as seems less likely and is indeed now generally discredited, the splenic changes are the cause of the disorder, then a long time passes before the disturbance of its functions is felt in the body generally. If, as is now widely believed, the spleen is only secondarily enlarged and the disorder is in the blood formation in the bone marrow, then even the body is remarkably tolerant of such a profound alteration in the circulating blood. On this view the excess of leucocytes and the occurrence of myelocytes are due to abnormal formation in the bone marrow, and the spleen is regarded as being simply distended and enlarged in consequence of the accumulation of these white cells in the pulp of the organ. Such fibrosis as may be present can easily be explained as the results of chronic irritation in the course of this procedure. But this view is not universally held. The spleen is still held by some to be a hæmatopoietic as well as a hæmolytic organ and the various phenomena of the development and diseases of the blood are explained by M. Marcel Labbé[4] by the assumption that all the hæmatopoietic organs—the spleen, glands, liver, and bone marrow—contain in early life both lymphoid tissue and myeloid tissue; that in adult life the bone marrow contains only myeloid tissue with remains of lymphoid tissue and that the glands and spleen have then chiefly lymphoid tissue with remains of myeloid tissue. Under conditions of disease the remains or potential tissues in each organ may develop or become actual. Thus the myeloid tissue of the spleen may develop so as to suppress or supplant the lymphoid elements and the lymphoid elements in the bone marrow may grow so as to suppress or supplant the myeloid tissue.

Turning now to the cases of lymphæmia, which are apparently less common than those of myelæmia, it is clear that as a rule the spleen is of less size. Of six cases from the Guy's Hospital records in two the spleen weighed only 18½ ounces after death, in another the edge of the spleen appears to have been two inches above the umbilicus, in another it was just palpable, in another the spleen was never with certainty palpable, but in the last it was very large indeed, reaching from the sixth rib nearly to the iliac crest, with its anterior edge only one inch from the middle line. In a case which I communicated to the Clinical Society of London last year, although the leucocythæmia or lymphæmia was extreme, the spleen could only be felt just beneath the costal margin, descending nearly an inch below it on deep inspiration. In the cases of acute lymphæmia described by Dr. J. Rose Bradford and Dr. H. Batty Shaw[5] of five spleens four were seen post mortem and they were respectively normal, slightly enlarged, 20 ounces in weight in a youth aged 19 years, and four and a half ounces in weight in a boy aged seven years. In the fifth case the spleen was just felt beneath the costal margin.

It is within recent years that cases of lymphæmia have been more frequently recognised, now that blood counts, and especially differential blood counts, are more frequently made, and I think it can be shown that there is greater variety among cases of lymphæmia than among cases of myelæmia. If the formation of lymphocytes takes place in many organs, in more organs than are capable of giving rise to myelocytes, the variety is perhaps in part explained. I think the following propositions will be found to hold good of lymphæmia or lymphatic leukæmia.

1. That the spleen is as a rule much smaller than in myelæmia, indeed, reaches no great size, and may be smaller even than occurs in cirrhosis and other conditions already mentioned.

2. That the lymphatic glands may not be very large at first or even at a late stage of the illness. In the first of the two cases which I read before the Clinical Society of London, clinically it was observed that "there is no increase of the glands in the neck, axillæ, and groins; the largest in the groin measures six millimetres by four millimetres, and post mortem a considerably enlarged lymphatic gland was found beneath the right parotid; the cervical glands were slightly enlarged but no mention is made of any other lymphatic glands being enlarged." In the second case, with an extreme degree of lymphæmia, a gland of the size of a pea was felt in the right posterior triangle and in each groin one or two slightly smaller. In Dr. Bradford's cases the lymphatic enlargement was often very moderate and certainly not always in proportion to the lymphocytosis.

3 That many organs are infiltrated with lymphocytes. In a case to which I have referred this was true of the heart, liver, spleen, kidneys, suprarenals, pancreas, salivary glands, lacrymal gland, thymus, and lymphatic glands. In another case which I communicated to the Clinical Society of London I think there is no doubt that the mammæ were infiltrated as well as the parotids and other organs.

4 That the thymus is very often involved. In three of the cases above alluded to there was hyperplasia of this organ. In one of them in the position of the thymus was a hard fibrous mass, six by four by three centimetres, very dense and containing a cartilaginous nodule. In another case, that of a boy, aged ten years (the first of the two cases already referred to), there was extensive dulness over the upper end of the sternum and post mortem the thymus was found to weigh 586 grammes, or 21 ounces, and was larger than a normal kidney. It was pale yellow on section, presented a fatty semi-transparent appearance, and contained numerous small and irregularly distributed hæmorrhages. Under the microscope the organ showed large spaces packed with lymphocytes and surrounded by a fairly well-marked fibrous stroma. In the third case, that of a boy, aged 15 years, the thymus is returned as much enlarged, pale, and speckled with hæmorrhages. As the kidneys, liver, spleen, and glands were described as packed with lymphocytes, it is probable that the thymus was in the same condition.

5. The duration is probably much shorter. At any rate there are some very acute cases belonging to this form of the disease. In the cases of Dr. Bradford and Dr. Batty Shaw the duration never exceeded eight weeks. The case above referred to, in which the region of the thymus was occupied by a hard fibrous mass, lasted only a calendar month. It was the case of a youth, aged 16 years, who was admitted for progressive weakness; three weeks previously he had been giddy and weak, without pain or sickness. On admission he was pale with a slightly enlarged liver and a spleen down to the umbilicus. The red corpuscles were 1,600,000; the leucocytes were 160,000, with many lymphocytes, a few eosinophiles, and one or two myelocytes. There were recent hæmorrhages in both retinæ. The temperature varied from 102·5° to 104° and 105·4° F. He had bleeding from the gums and diarrhœa and he died a week after admission. Post mortem the cervical glands were enlarged, red, and soft; the right bronchial glands were very much enlarged. The mesenteric glands were large, red, and soft, and the glands in the portal fissure were large. There were numerous superficial hæmorrhages in the pericardium. The liver was tough, fibrous, cirrhotic-looking, weighing 53 ounces, and there was early ulcerative colitis of the whole large intestine. Though the clinical history was of only one calendar month's duration the post-mortem results suggest latent disease somewhat earlier. In another case, that with the large, pale, speckled thymus, the duration was only two months. A week before admission the patient had pain in the neck, the axilla, and the groins and next day bumps were seen. On admission the submaxillary, the submental, the cervical, the occipital, the axillary, the inguinal, and the epitrochlear glands were enlarged. The leucocytes numbered 12,500. A month later the spleen and liver were moderately enlarged. At this time the leucocytes had risen to 43,000 and 48,000, with 95 per cent. of lymphocytes and only 4·4 of polymorphonuclears. The tonsils, large at first, were getting much larger. Ten days after the last note the leucocytes were 116,000, then 126,000. The patient had hæmorrhage from the mouth which was believed to come from the tonsil and he died in two months from the first symptom. Post mortem the various lymphatic glands were enlarged, dead white in colour, with small hæmorrhages. There were petechiæ under the pleuræ and the pericardium. The liver weighed 103 ounces. The spleen was of a pale crushed-strawberry colour with several infarcts.

---

[4] Le Sang, Paris, 1902.

[5] Transactions of the Royal Medical and Chirurgical Society, vol. lxxxi., 1893, p. 343.

The tonsils were much enlarged with extensive sloughing on the surface. In each of the two cases I showed at the Clinical Society of London the duration was three months.

6. In these cases of lymphatic leukæmia the leucocytosis even at the time of death may be relatively slight—that is, not above 50,000, and it may come on relatively slowly—that is, the lymph-glands may be found enlarged first without leucocytosis so that a condition of Hodgkin's disease is simulated, and no doubt it is just such cases as these last which explain the belief which has been held that the diseases are the same, or that leucocytosis is an accident in the course of Hodgkin's disease. In illustration of this relatively slight leucocytosis in some cases I may quote again one of the cases already alluded to in which, after two months' illness with much enlargement of the parotid glands and the internal organs, the leucocytes amounted only to 15,000, of which more than half were lymphocytes—i.e., 46·6 per cent. small and 9·3 large, while the polymorphonuclears took a second place with 42 per cent. 18 days later the leucocytes had risen only to 50,000, but the lymphocytes were now 94 per cent. small and 3 per cent. large, thus accounting for all but 3 per cent. of the total leucocytes. Another case was that of a man, aged 61 years, who observed a swelling in the neck about Christmas, 1902. A month later there were swellings in the axilla and groin and the abdomen became distended. He came under observation in October last; the glands in the neck, axillæ, and groins were enlarged, the liver was enlarged, and the spleen just palpable. The glands in the neck were of the size of beans and those in the axillæ and groins of the size of pigeons' eggs. The white corpuscles were 6250, but no differential count was made 17 days later the count was 91,800, with small lymphocytes 76 per cent., large lymphocytes 15 per cent., and polymorphonuclears 9 per cent. Eight leucocyte counts during the next seven weeks at about equal intervals gave figures varying from 66,000 to 111,000, but more often over 100,000 (average 97,000).

It is clear that lymphocythæmia, lymphæmia, or lymphatic leukæmia presents itself in at least three or four different forms which I have already illustrated directly or by reference. First, there are the cases called acute leukæmia, described by Fraenkel and by Dr. Bradford and Dr. Batty Shaw, in which sloughing of the gums or gingivitis is a prominent feature, in which the duration is a matter of six or eight weeks, and in which the large lymphocytes form the bulk of the leucocytes present. Secondly, there are other acute cases which may be fatal in as short a time as three months, possibly less or more, in which sloughing of the gums or gingivitis is not a feature and in which, at any rate, the lymphocyte increase may be due to the small lymphocytes. Whether these two groups are distinct or whether, as seems much more likely, they will be found to overlap or interdigitate, I am unable at present to say. In one of the cases above mentioned there was ulcerative colitis and in another sloughing of the tonsils, but no distinction was made between small or large lymphocytes in the blood counts. In neither of these two groups is an early or pronounced enlargement of accessible or even of deep-seated glands a necessary feature.

The third group may be represented by the case of the elderly man just given, in which the glandular enlargement is the prominent feature of the case and in which the duration is relatively long; for instance, this patient was alive in the thirteenth month of the complaint.

The following case seems to me to form a fourth category.

A woman, aged 29 years, was under the care of my colleague, Mr L. A. Dunn, for a swelling in the neck which was partly a growth of the thyroid body and partly a mass of enlarged cervical glands, attributed to decayed teeth. Mr. Dunn removed the thyroid growth but left the glands untouched. Nine months later she became faint in the street and was taken to the Westminster Hospital, where she says she was told that she had leukæmia. She was in ten days and then returned home; she was better for a time but again became ill, and about two months later came into Guy's Hospital under my care. She was anæmic; there were a few enlarged glands in the neck, the groins, and the axillæ, apparently from one-third of an inch to half an inch in diameter. The spleen reached to one inch from the middle line and the lower end nearly touched the iliac crest. The vertical extent was estimated at 11 inches. The liver reached five inches below the costal margin and below this was a solid lobulated mass reaching one inch lower than the umbilicus and four inches below the liver. This was thought to be either the kidney or a mass of large glands. Enlargement of the thymus was also suspected from impaired resonance over the upper sternum. The blood count was as follows: red corpuscles 900,000 and leucocytes 42,000, of which the greater number were small lymphocytes, but there were some eosinophiles and a few doubtful myelocytes. She died five days later. The cervical, bronchial, mediastinal, and mesenteric glands were enlarged. The thymus was enlarged, measuring ten by four and a half by six centimetres. The liver weighed 111 ounces and the spleen 91 ounces. This was of uniform dark maroon colour, with no pale areas, but three small triangular almost black infarcts. The kidneys were of great size, weighing together 37 ounces; they presented an extraordinary appearance of mottling with alternate patches, streaks, and blotches of maroon colour and pure white. Of the bone marrow I have no post-mortem record; but during life she appeared to be tender over the sternum and the bones of the arms, but she was perhaps too ill for these results to be quite trustworthy. In the unusual size of the spleen and the relatively long duration of the case, if the glandular enlargement of 11 months previously can be accepted as a commencement, we have a course somewhat different from that of the others. The relatively small degree of leucocytosis is also notable. It is to be regretted that a report of the histological examination is not forthcoming.

Mixed cases of leukæmia are believed to occur—that is, combined cases of spleno-medullary and lymphatic leukæmia. But they must be rare. As I have already shown, and as is well known, the spleen may be enlarged in association with lymphatic leukæmia and, as the last case shows, the spleen may be nearly as large (91 ounces) as the average (97 ounces) of spleen weights in 16 unselected spleno-medullary cases. But a mixed case should mean nowadays one of combined lymphæmia and myelæmia. There is only one case in these I have now brought before you which was regarded as a leukæmia splenica et lymphatica. But it is entirely inconclusive because the records of the blood examination are wanting and the coexistence of enlarged lymphatic glands with an enlarged spleen may occur in a pure lymphæmia.

It is, perhaps, going a long while back, but in 1873 I brought before the Pathological Society of London a case of leucocythæmia in which a huge spleen was associated with general enlargement of the glands, the growth of lymphoid deposits under the pleura, infiltration of various organs with leucocytes (including the testes), and a condition of blood in which small uninuclear leucocytes, as well as large multinuclear leucocytes, were certainly present; but what the staining methods of the present day would have revealed I am unable, of course, to say. I can, however, say this, that I have not again met with an exactly similar case, unless the last case of "splenomegalic lymphæmia" which I have just read is one. I must, of course, admit that my case of 30 years ago may have been a lymphæmia rather than a spleno-medullary or a mixed case. And certainly authors have for the most part accepted the view that lymphæmia and myelæmia are essentially different.

Were I discussing these diseases, these forms of leucocythæmia, for themselves alone, and not as I have said "some disorders of the spleen," I should have to offer my excuses as well as my regrets for the little information I have brought forward as to the condition of the bone marrow in these cases. I must be content with reminding you that the bone marrow has been found altered not only in spleno-medullary leukæmia but also in lymphatic leukæmia, and though they appear to be extremely rare cases of leukæmia without change in the glands or spleen are said to occur.

The feeling of the majority of observers is clearly that the spleen is in both forms secondarily affected, that it is stuffed with leucocytes unduly proliferated from the bone marrow in the one case and either from the lymph glands or conceivably from the bone marrow in the other.

SPLENOMEGALY WITH CHRONIC CYANOSIS AND POLYCYTHÆMIA

I may briefly call attention to another condition in which splenic enlargement takes place—namely, chronic cyanosis with polycythæmia; that is, increase in number of the red blood corpuscles. Dr. Parkes Weber read a case of the kind before the Clinical Society of London on March 18th. Dr. Saundby and Dr. J. W. Russell[6] published a case two years ago, Professor Osler published four new cases in August, 1903,[7] and other cases have been recorded in America and on the continent. In Dr. Russell's case the spleen weighed 48 ounces, in Dr. Weber's 23 ounces, but in two of Professor Osler's it was not demonstrably enlarged.

---

[6] THE LANCET, Feb. 22nd, 1902, p. 515.

The nature of these cases is so far obscure. Dr. Weber found red transformation of the marrow of the left humerus, the left femur, and the left tibia. The marrow contained numerous nucleated cells representing myelocytes, eosinophile myelocytes, erythroblasts, and large endothelial cells and giant cells, and thus appeared to consist largely of tissue engaged in the formation of red blood corpuscles. And he regards the condition as a disease primarily of the bone marrow. But Dr. Russell had seen his patient with an enlarged spleen at least six years before the condition of cyanosis developed. In both these cases the spleen appeared to be only engorged and not to present any indication of being primarily diseased.

CHLOROMA.

I may still more briefly allude to a condition in which the spleen is involved—namely, that of chloroma. In this rare disease, in which lymphoid tumours of a green colour occur throughout the body, the blood presents the characteristics of a lymphocythæmia or lymphæmia and the spleen is enlarged by infiltration with lymphoid deposits or lymphocytes. The relation between chloroma and lymphatic leukæmia is believed to be very close but there remains no doubt a great deal of work to be done on both these conditions.

PRIMARY AND SECONDARY ANÆMIAS.

The attempt to distinguish between primary and secondary anæmias seems here to fail completely. The recognised primary anæmias are: (*a*) chlorosis and (*b*) pernicious anæmia. Among the secondary anæmias must be classed: (*a*) splenic anæmia, (*b*) infantile splenic anæmia (von Jaksch's), and (*c*) the anæmia of leukæmia. But after we have been searching into the pathology of these diseases, what essential difference do we see between these groups? In one of the primary anæmias, pernicious anæmia, a large number of facts have been collected which at least suggest, if they do no more, that some kind of toxic or infective process is at work which is not any obvious defect of food, or loss of blood, or continuous vital strain, or primary disease of any organ charged with blood formation; for although the spleen is sometimes enlarged it is not so constantly; it is often indistinguishable from that of health, and, moreover, the share of the spleen in the formation of the blood is at least doubtful. On the other hand, in splenic anæmia of adults the only explanation which at all satisfactorily introduces the spleen as a part of the causation regards the splenic lesion not as the primary condition but as an intermediate factor between absorption of toxins from the intestines and the morbid condition of the blood.

Secondly, in infantile splenic anæmia intestinal poisoning is again rather widely accepted as the essential cause and the splenic enlargement is looked upon as rather an accident than otherwise, so that in a great number of cases very little is said of the condition of the spleen beyond the fact that it presents an enlargement which is very different in different cases.

With regard to leukæmia the early impressions seem to have been twofold: one that the anæmia was due to the disease of the spleen or glands or marrow, whichever one or two or three were involved; the other that the extreme leucocytosis either necessitated a smaller number of red corpuscles as a matter of crowding out, or that the undue proportion of leucocytes represented an imperfect condition of the blood, of which the red corpuscles were the highest development. But with regard to the spleen it is almost certain that the primary lesion does not lie there, nor even in lymphatic leukæmia is it certain that the cause lies in the glands.

Thus we have reason to believe that we can see some cause in an anæmia regarded as primary and that in a form regarded as secondary the cause does not really lie in the organs originally thought to be primarily at fault. Indeed, primary is almost as unsatisfactory a group as idiopathic. It is only valid so long as our ignorance lasts or till fresh facts come before us to advance our knowledge. It is, indeed, no question of causeful or causeless cases; it is only the question of whether the essentials of the blood are diminished by destructive hæmolysis or by failure of production—i.e., anhæmogenesis or deficient hæmogenesis. Or, thirdly, whether the deficiency of essentials is only relative or due to an increased quantity of plasma.[8] Hæmorrhage is a coarse hæmolysis; pernicious anæmia is a hæmolysis in detail. Starvation is a coarse anhæmogenesis; various processes of disease are anhæmogenesis in detail. It is for us to find out what in each case are the causes of hæmolysis or anhæmogenesis. Of hæmolysis we have other examples in chlorate of potassium poisoning and in paroxysmal hæmoglobinuria. As a cause of the hæmolysis of pernicious anæmia we are led to look to some infective process, peculiar in this—that it alone, if it is a single toxin, should produce a hæmolysis while so many others do the reverse. Of anhæmogenesis or deficient hæmogenesis we have examples in nearly all the cases where anæmia follows upon prolonged infective disease. It may be very difficult to estimate the share which is to be attributed to actual deficiency in food supplied and that which other processes may have. But there are enough instances of anæmia occurring in cases when the food is not necessarily much diminished to make it probable that if the processes of splenic anæmia in children, splenic anæmia in adults, and chlorosis are due to some kind of unbottled poison inhibiting the process of blood formation, the same is taking place to account for the anæmia of syphilis, rheumatism, phthisis, empyema, prolonged sepsis from whatever cause, Bright's disease, and many other allied conditions.

CONCLUSION.

In looking back on these "disorders of the spleen," of which my review has been so fragmentary and imperfect, one is brought to the conclusion that the spleen is more sinned against than sinning; that it is rarely responsible for the lesions which it suffers or for the complaints with which it is associated; that in the various infective disorders, in splenic anæmia, and in infantile anæmia it is probably poisoned from without; that in the different forms of leukæmia it is overcharged with the excess of leucocytes; and that only in splenic anæmia as yet is the charge seriously made against it, that itself having been poisoned from the bowel it subsequently inhibits by fresh production of poisons the formation of the blood. It is in these diseases that good results have sometimes been obtained by splenectomy, though it must be admitted that death has sometimes taken place shortly after the operation. In the other cases the primary condition must be treated, and in so far as that can be controlled or will spontaneously recover the enlargement of the spleen may be expected to subside.

In spleno medullary leukæmia considerable reductions in size of the enlarged spleen have occurred under arsenic and sometimes under inhalations of oxygen, but a relapse appears in this disease to be almost inevitable. The spleen has also been extirpated for malarial enlargement, and it is recorded[9] that of six cases operated on four recovered.

I have, Mr. President and Gentlemen, to express to you my gratitude for your kind and considerate attention during these three lectures, which again I cannot help thinking will have fallen very far short of what you have a right to expect.

A CASE OF PERFORATED GASTRIC ULCER IN A BOY AGED 13 YEARS; DISEASED APPENDIX; OPERATION; RECOVERY.

BY W. WATSON CHEYNE, F.R.S., F.R.C.S. ENG.,
PROFESSOR OF CLINICAL SURGERY, KING'S COLLEGE;
AND
HAYDOCK WILBE, M.D. DURH., L.R.C.P. LOND.,
M.R.C.S. ENG.

ON March 16th, 1904, the patient, a boy, aged 13 years, who had previously been perfectly well, complained of some stomach-ache during the afternoon when returning from school. In the evening this became worse and he asked to be allowed to go early to bed; his mother put a hot water bottle over his stomach which relieved him in a few minutes. He got up on the morning of March 17th much better and practically felt well except for a little abdominal pain when stooping; the exact position of the pain was not well defined. He, however, asked to be allowed not to go to school. In the morning he had some Eno's fruit salt and ate a very good dinner that day. About an hour after dinner he began to complain of severe abdominal pain and very soon became seriously ill. Dr. Wilbe was sent for and saw him between three and four o'clock in the afternoon and found him complaining of violent pain in the abdomen which he could not localise very precisely but he placed his hand towards the right side and about the umbilicus. He found him very collapsed, with a pulse of about 130, with marked rigidity of the abdomen and tenderness over the whole abdomen. The symptoms were especially marked towards the right side and upper part of the abdomen. There was no vomiting. The temperature was normal. Mr. Watson Cheyne saw the patient at 8.30 in the evening. At that time the boy looked extremely ill; there was no abdominal respiration; the alæ nasi were moving; there were marked rigidity of the whole abdomen and general tenderness but no abdominal distension. The pain and rigidity were not well localised but were on the whole most marked towards the upper part on the right side. The abdomen was tympanitic everywhere but there was no distinct obliteration of the liver dulness. There had been no vomiting. The temperature was normal. The conclusion come to was that there had been a perforation of some abdominal organ, and from the general history and symptoms pointing more towards the right side and the probability at that age that the trouble was of the form of a fulminating appendicitis an incision was in the first instance made over the seat of the appendix. On exposing the peritoneum it at once bulged out in the wound and on puncturing it gas whistled out. On enlarging the opening the small intestines were forced out, partly by the gas and partly as the result of the great rigidity of the abdominal walls, which had not become relaxed under the anæsthetic. Some thin whitish fluid also came out of the abdomen. For the most part the intestines were normal in appearance but on some of the coils of the small intestine, which came apparently from the left side of the abdomen, there were some flakes of lymph. The pelvis and lower part of the abdomen were well irrigated with salt solution till the fluid returned clear, and the intestines were then, gradually but with considerable difficulty, returned to the abdominal cavity. The cæcum and appendix were now pulled out. The appendix was long, thickened, a good deal reddened, and contained a large concretion; but there was no perforation of the appendix nor of the cæcum in the neighbourhood. The appendix was removed in the usual manner.

---

[8] Lorrain Smith. Transactions of the Pathological Society, 1900, p. 311.

[9] Scheube: Warm Countries (English translation), p. 169.

As it was evident that there must be some graver lesion than the condition of the appendix to account for the state of matters and as practically the whole of the small intestine had been seen, and as also there was no fæcal material present in the abdominal cavity, a second incision was now made over the stomach. At first nothing seemed to be amiss. The body of the stomach and the pyloric end seemed perfectly healthy; the region of the duodenum was examined; the stomach was turned over and the posterior surface palpated and still no perforation was found. On further examination of the anterior surface high up towards the cardiac end some turbid fluid and gas bubbled up. After wiping that away and directing a good light into the cavity high up under the diaphragm, a round perforation was found on the anterior surface of the stomach about an inch from the cardiac end which would have admitted a small slate pencil. From this perforation gastric juice and gas were escaping. There was no thickening around; it was a clean punched-out hole and all the structures in the neighbourhood seemed perfectly healthy. The edges of the ulcer were inverted with a row of catgut sutures and a second row was then put outside. The peritoneal cavity in the neighbourhood was thoroughly sponged out and the whole cavity again washed out with salt solution. A drainage tube was passed down towards the seat of the perforation, another towards the left loin, and another (from the lower wound) towards the pelvis. The rest of the wounds were stitched up. The boy stood the operation very well and his pulse after it was 120. On the night of March 18th the wounds were dressed. There had been very little discharge. The abdomen was very much distended. The pulse was 130 and the temperature was 99·2° F. There was a good deal of tenderness everywhere. No flatus had been passed. There was very little sickness. The boy had not slept and was somewhat excited. On the whole he looked rather better than he did on the previous day. He had been having rectal feeding with sips of water by the mouth. On the 19th the abdomen was still in much the same condition but the patient did not seem any worse than he was on the 18th. The pulse and temperature were the same. There was less tenderness at the lower part of the abdomen and there had been no vomiting. A little flatus had been passed but not enough to give him relief. Enemata had been given but without any result. At our visit in the evening we gave him an enema again and evacuated some fæces and flatus which relieved him very much. The drainage tubes were pulled out and the greater portion cut off, leaving only a small part projecting into the peritoneal cavity. There was very little discharge. On the 20th the patient was distinctly better. The abdomen was not so tense but still very much distended. He had passed a little flatus and slept a little during the night. The tubes were left out. There was very little discharge. He began to take small doses of salines and salol. On the 22nd the patient had a good action of the bowels in the afternoon and the abdomen was much less distended. He was very much better. On the 23rd feeding by the mouth was begun. From this date the boy went on uninterruptedly well. Solid food was allowed on April 1st. The wounds had completely healed on the 13th. The patient was allowed up for the first time on the 14th and went out in a bath chair. On the 25th the boy was in high spirits and had apparently perfectly recovered.

The interest of this case lies, in the first place, in the occurrence of a perforating gastric ulcer in a boy, aged 13 years. We can find no record of perforation of the stomach in a male at such an early age. In this case the ulcer was typically a peptic ulcer. Gastric ulcers have been found in younger children but apparently only of a tuberculous character. Thus Dr. G. F. Still[1] recorded five examples of tuberculous ulcers of the stomach in children, in three of which histological and bacteriological examination had been made with positive results. In all cases the ulcers were small. The first was a child, aged three and a half years, who was admitted with vomiting and ascites due to tuberculous peritonitis; the second was a child, aged ten months, suffering from cough and tuberculous meningitis, and, as shown after death, from generalised tuberculosis; the third was a case of tuberculous peritonitis; the fourth was a boy, aged nine years, who was also affected with tuberculous peritonitis; and the fifth was a child, aged two years, suffering from the same disease. The author had only found five cases out of 226 necropsies. There were no clinical symptoms associated with them. In one of the five cases perforation had occurred but extravasation had been prevented by adhesions. In the above case there was no sign whatever of tuberculosis either about the stomach or the abdomen generally nor was there any reason for suspecting it. As to the cause of the ulcer in this boy we cannot make any suggestion and there were no previous symptoms whatever leading to a suspicion that anything was wrong with the stomach.

The second point of interest is that, partly as the result of the symptoms pointing somewhat towards the appendix and partly on account of the great rarity of the actual condition, the appendix was in the first place cut down upon and a *diseased appendix* was found. The condition of the boy was so extremely bad that one was very much tempted to hope that that might be the cause of the whole trouble; but the presence of free gas in the abdomen made it absolutely certain that perforation of a hollow viscus other than the appendix must have taken place, and the absence of fæcal material in the abdominal cavity and the fact that practically the whole of the small intestines had passed under review when they were forced out of the wound led us to assume that this perforation must have taken place either in the stomach or duodenum.

The third point of interest is the situation of the ulcer. It was situated so high up and was so difficult of access that its presence was nearly overlooked. Before it was found the whole of the lower part of the stomach had been examined, the duodenum had been investigated, the stomach had been turned up and the posterior part searched, and had it not been that we were convinced that there must be a perforation, and that a further search was made towards the upper part of the stomach, the condition might have been overlooked.

200 CASES OF ACUTE LOBAR PNEUMONIA.[1]

BY JOHN HAY, M.D. VICT., M.R.C.P. LOND.,
PHYSICIAN TO THE LIVERPOOL STANLEY HOSPITAL; ASSISTANT PHYSICIAN TO THE HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, LIVERPOOL.

THE following paper is based upon the observation of over 200 cases of acute lobar pneumonia. I have confined myself more particularly to a series of 150 cases upon which I made notes and kept a record of the treatment. These observations and notes were made in the years 1899 to 1901, while I was acting as assistant medical officer in Mill-road Infirmary, Liverpool, and I would like to avail myself of this opportunity to thank Dr. Nathan Raw for kindly allowing me to make use of this material.

There is no intention on my part of describing pneumonia as a clinical entity—this has been done frequently by those much more fitted for the task than I; nor do I propose to lay before you the result of any laboratory research into any special feature of the disease, but while in daily contact with this large number of cases certain points in the diagnosis, prognosis, and treatment impressed themselves upon my mind and I am here attempting to put these points before you in the hope that I may have the benefit of your much larger experience. Much of what follows is probably not new but is to my mind insufficiently emphasised in the literature; some is heterodox and to it I beg your attention and a sympathetic attitude, for it is with much diffidence that I am here to support what I know is unorthodox.

It is essential that we should from the first have a definite conception of the type of case which has been under observation. The following statistics will show us almost at a glance. In 150 cases there were 33 patients below 20 years of age, with a mortality of 9·1 per cent; 89 between 20 and 50 years of age, with a mortality of 41·5 per cent.; and 28 over and including 50 years of age, with a mortality of 75 per cent. The total mortality was 61, or a death rate of 40 5 per cent. 21 of these patients, or one-third of the fatal cases, were admitted moribund and died within 24 hours of admission. On eliminating these there are still remaining 129 cases with 40 deaths, or a mortality of 31 per cent.

Alcoholic excess is recognised as one of the most important of the etiological factors in pneumonia, and in this series it is much in evidence. In 65 of the 150 cases a history of alcoholic excess was obtained; in other words 43 3 per cent. [illegible] Of these [illegible] nt. among [illegible] of view we find that amongst the 61 fatal cases 37 were excessive drinkers, that is 60 per cent. of the total mortality. Everyone knows how difficult it is in many cases to obtain a history of alcoholic excess, therefore in all probability the proportion of alcoholics is still larger. These patients were paupers with their powers of resistance greatly lowered in many cases by alcohol, underfeeding, overwork, and exposure. Such was the material which I had the privilege of observing—the class of case which teaches most, for it requires every possible therapeutic aid. All will admit that many cases of pneumonia are such that the patients get well with almost any, or even perhaps in spite of, treatment; some, on the other hand, are doomed to death from the first, so malignant is their attack, and it is really only that small number of cases in which the question of the fate of the patient is in the balance which offers the greatest scope for treatment and where one feels that careful, accurate, and prompt measures turn the balance in the patient's favour.

Physical examination of the patient.—Everyone admits that the general clinical signs of pneumonia are of more importance in the diagnosis than mere local physical signs and it would be futile here to enumerate the typical symptoms and clinical signs of an acute case, but there are several points of practical value which I feel are worthy of mention. Admitting that we must from the first take every care to spare the heart, still there can be no doubt that a careful, thorough examination should be made not only at the first but also whenever there is the slightest fear or doubt as to the changes and processes taking place; more especially do I believe this to be necessary towards the end of the first week. In order to simplify this examination I am convinced of the value of a shirt open not only in the front of the neck but also down the whole length of the body. With a shirt of this kind the front of the chest, the abdomen, and the axillæ can be bared without moving the patient. There is too much hesitation in laying bare the chest, the axillæ, and the abdomen, at any rate in males. The fear of such patients "catching cold" is groundless and the great advantage of exposing the whole area to view at the same time is obvious. After a careful examination of the apices in front with the arms lying by the side, the patient should be asked to place both his hands well above his head; in this position both axillæ are easily examined and I am confident that there is no part of the chest which lends itself more readily to examination or which better repays careful attention. In the right axilla you have a portion of all three lobes and I have noticed the frequency with which any doubt in diagnosis is cleared up by careful auscultation and percussion of this part of the chest. If the pneumonia is basal in site the lesion almost always approaches the great fissure as it runs across the axilla and one can demonstrate the definite change of note on percussing from the middle or upper to the lower lobe. If the upper lobe be diseased it is easily examined from the axilla, extending as it does from the fourth rib up to the apex of the axilla and covered with a minimum thickness of chest wall, whilst if the examination be made from the front you have the pectoral muscles, and if from behind the scapular muscles, interfering with its examination. When the pneumonia happens to be central in position the physical signs usually show themselves first in the axilla and are late in appearing. This delay in the appearance of the physical signs of consolidation may, however, be a feature in a case quite apart from the existence of central pneumonia. If the toxæmia be very severe and the patient delirious, with bloodshot eyes, it is occasionally not at all easy to diagnose the condition from that of typhus fever and then any physical signs pointing to commencing consolidation are important. In several such cases I found that as the consolidation approached the surface in the axilla the first changes to be noticed were the appearance of a tympanitic quality about the percussion note and a diminution of the breath sounds, together with a prolongation of the expiratory murmur. This diminution of the breath sounds, one of the most important of the early signs of pneumonia, is probably due to an engorged condition of the lung interfering with the normal elasticity "and consequently much restricted respiratory expansion." This is noted by Lewis A. Conner and George E. Dodge[2] in a paper to which I will refer later. On examining the back when the pneumonia is affecting the lower lobe the physical signs are most often well marked about the seventh, eighth, and ninth spaces just within the angle of the scapula, and when examining with the patient on his side in the early stage of the disease before consolidation is well defined it is well to remember that the side which is uppermost nearly always yields to percussion a higher pitched note. This is probably due to the fact that when one percusses the upper side one is percussing on to the spinal column, whereas on percussing the under portion of the back the bed will tend to act as a resonator and so yield a fuller note. When in such a case there is any doubt as to the cause of the impairment of note one of two things must be done—either you get the patient to sit up and to lean forward, which is undoubtedly the best method so long as the patient is sthenic and vigorous, or you have the patient lying first on one side and then on the other, and in that way check your first impression. As medical tutor to the Royal Infirmary, Liverpool, I have pointed out this difficulty to the students for the last three years and was much interested to find it discussed in the *American Journal of the Medical Sciences* by Lewis A. Conner and George E. Dodge, apparently their communication being the first mention in the literature of this peculiarity. I had already written my paper when I read their article and am glad to support their statement.

In the examination of the heart I found it very useful after having carefully percussed out the deep cardiac dulness to mark it out with a piece of lunar caustic. This is done at the first examination; the marks persist and are of the greatest help in showing any alteration in the extent of the cardiac dulness due to the disease, whether the cardiac failure must be anticipated by cardiac stimulants, more especially in pneumonia by alcohol. I do not agree with this conclusion and hope to give you good reasons for my view. That these signs are the signs of cardiac failure is true, that a cardiac stimulant or tonic is required is evident, but to exhibit alcohol would, I believe, be unsound treatment. Alcohol has its place in the treatment of pneumonia both during the acute stage and convalescence, but I do not believe that its rôle is that of a cardiac stimulant, for as Sir Samuel Wilks says in speaking of it[5]: "It is difficult to know why such a remedy is called a stimulant. From the change of name to sedative I have got much practical good."

---

[1] A paper read before the Liverpool Medical Institution on Nov. 19th, 1903.

[2] American Journal of the Medical Sciences, vol. cxxvi., p. 389.

You must all have noted the steady change of opinion in the profession as to the value of alcohol in pneumonia. At the present time nearly every writer warns his readers of the danger of overdosing patients with alcohol and the necessity of withholding it as long as possible. Out of many possible instances may I quote one. Burney Yeo,[6] says: "The routine administration of alcohol in pneumonia, especially in the early stages with the idea of preventing cardiac failure later is, we think, a serious error. Alcohol produces vasomotor paresis and causes dilatation of the vessels and *it must therefore aggravate or induce tendencies to vascular engorgement.*" (The italics are mine.) "It acts like a poison to many persons and causes considerable nervous and general depression after its first stimulating effect passes off; it increases the amount of toxic substances in the blood and the elimination of considerable quantities of alcohol must impose a severe strain on the already overtaxed organs of excretion." That, in the light of the views held by Todd and his followers, is indeed a great advance. Even in 1900 in this institution I heard a member state that he always put every "pneumonia" on six ounces of brandy in the 24 hours, together with ammonium carbonate and digitalis —routine treatment with a vengeance! There was a time when it was customary to bleed pneumonias and when this method of treatment was supported by all the acumen and experience of the lights of medicine. The public at that time held the same views and history records that a medical man was sued for damages on the ground that he had caused the death of his patient by neglecting to extract the customary ounces of blood. A different version of the same story occurred recently. This time an action for damages was taken out against a physician on the death of his patient because the patient had not received alcohol. The public used to swear by bleeding, now they swear by brandy. The profession have put venesection into a secondary position in the treatment of pneumonia and already they have begun to modify very considerably their views as to the value of alcohol.

The action of alcohol on the circulation is briefly as follows. Its primary action is on the mucous membrane of the mouth, œsophagus, and stomach, and in virtue of this action it undoubtedly acts reflexly as a cardiac stimulant. This stimulation is neither prolonged nor powerful. After its absorption alcohol exerts its specific action—dilating the peripheral blood-vessels and lowering the blood pressure, thus tending to empty the arteries and to fill the veins. On the heart itself, directly, alcohol seems to have no effect at all; in large doses it enfeebles it.[7] Such is the opinion of Professor C. S. Sherrington. Its action on the centres in the bulb is from the first depressant. As a food it need not be considered. It is not given as a food. The indications for its exhibition, according to those who advocate it, are those of cardiac failure and it is given to meet that failure. It is oxidised in the body and therefore does give rise to heat and energy but this is of secondary importance. It is undoubtedly given for its specific action on the circulation and nervous system. Bearing these facts in mind, in what way may alcohol be employed with advantage in pneumonia? The total action of alcohol on the heart being depressant it is futile to give it in cases of commencing cardiac failure with the idea that you are combating that failure by giving a specific cardiac stimulant. The peripheral vessels are, as a rule, sufficiently dilated in response to the pyrexia and there is no useful object to be gained by further dilating them with alcohol. During the initial rigor, when the peripheral vessels are all contracted and there is marked internal congestion, relief and comfort may be obtained by suitable doses of alcohol in the form of hot drinks; or again occasionally after the crisis during the period of convalescence small quantities of alcohol might be used with benefit to prevent contraction of the peripheral vessels and consequent strain on the enfeebled heart.

I think there is some ground for the belief that chronic alcoholics take their nourishment during the fever with more comfort and satisfaction if at the same time they receive a small quantity of spirits and water, though Sir William Broadbent says that "in no cases should they be given in the early stages even when the patient has habitually taken alcohol in excess and may be thought to have become dependent upon it; the safer plan is to withhold them until it is clear that they are necessary." I have seen persistent vomiting initiated by brandy on several occasions in those previously unaccustomed to spirits. The narcotic action of alcohol is occasionally of value in securing sleep and is best given either as recommended by Sir Douglas Powell combined with infusion or tincture of digitalis or in conjunction with a small quantity of morphine given hypodermically. These are the conditions in which, in my opinion, alcohol can be given with benefit. To exhibit it in the quantities so commonly ordered in serious cases is, as Burney Yeo wisely points out, to hasten that very condition of cardiac asthenia which it is our one aim to prevent.

We have not time to consider the toxic effects of alcohol on the protoplasm of the heart muscle accentuating the degenerative changes inaugurated by pyrexia and toxæmia; its action in binding the oxygen more firmly to the hæmoglobin, thus preventing the fullest supply of oxygen to the tissues; its action in shortening diastole or the resting period of the heart's muscle; or its action in interfering with the nutrition of the heart muscle by diminishing the flow of blood in the coronary arteries and the elimination of waste material, both of which take place mainly during diastole. All these factors, slight in themselves, tend to the production of cardiac failure. I quite realise that I shall be met with the query, "To what end are all these statements when we know what pneumonia is? We have seen patients live who but for alcohol would have died; we have given alcohol and watched its effects; we are convinced it is a cardiac stimulant." My answer to this is that these convictions are based upon statements and observations which have not been subjected to a sufficiently searching criticism. Tradition is largely responsible for these beliefs and arguments of the *post hoc propter hoc* type have perpetuated them.

At the present time there are two factors which act most powerfully in prolonging the life of the orthodox views as to the administration of alcohol. The first is that students are biased from the very beginning—very few have ever seen a severe pneumonia treated without alcohol and, in fact, I might say that the same holds good amongst qualified men, only a small percentage of whom have watched or treated cases of grave pneumonia in which alcohol was not administered. A student becomes qualified and enters on practice believing that he must administer alcohol under certain conditions. In the majority of instances not the shadow of a doubt ever crosses his mind as to its efficacy and the result is that if the patient lives after the exhibition of large doses of brandy he believes that the brandy was largely instrumental in the recovery, whilst if the patient dies he consoles himself with the thought that everything possible had been done to prevent the fatal issue. The second factor is possibly even more potent, though I hardly like to mention it. The general public believe in brandy. It is "the stimulant," and if a friend or relative is seriously ill they are never happy unless brandy or some other alcoholic drink is ordered. It takes a strong-minded medical man to withstand this, and although one may not care to admit it lay opinion in this matter cannot but have a far-reaching effect. Unless a man has very definite reasons for preferring to do without alcohol in the treatment of a case he will naturally yield to the openly expressed desires of the patient's friends and relatives. When anyone considers alcohol a necessity, exhibits it on the first appearance of an unfavourable sign, and consistently follows this line of treatment in blind faith, I hold that the value of his opinion must be much impaired, for his experience is hopelessly one-sided—he knows only one aspect of the question. One must admit, I think, that the above describes the majority of men practising at the present time. That the medical men take its value for granted and the general public demand its exhibition are, in my opinion, the two factors which are chiefly responsible for the persistent belief and faith in alcohol as a cardiac stimulant. I will admit that for two years after being qualified I could not conscientiously have treated a serious case of pneumonia without ordering alcohol. One of my teachers, a man for whose opinion I still have the very highest respect, taught me that the treatment of pneumonia was, in brief, "bed, poultice, and stimulants according to the pulse," and that treatment I followed.

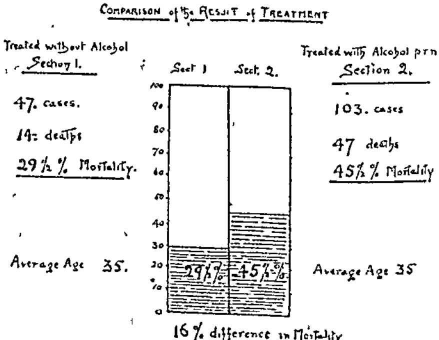
[6] I. Burney Yeo: Manual of Medical Treatment, vol., i. p. 581.

[7] John C. Hemmeter: Studies from the Biological Laboratory of Johns Hopkins University, 1889, vol. iv., No. 5.

In 1897, when house physician in the Royal Infirmary and later at Mill-road Infirmary, I carefully watched the effect of alcohol in pneumonia and my faith in its efficacy as a cardiac stimulant slowly began to be shaken. In fact, I began to wonder whether it was not even detrimental to the patients to receive alcohol in the orthodox quantities. While acting as assistant medical officer in the latter infirmary I had the opportunity of carrying out a line of treatment in which the patients did not receive any alcohol and I now lay before you the results.

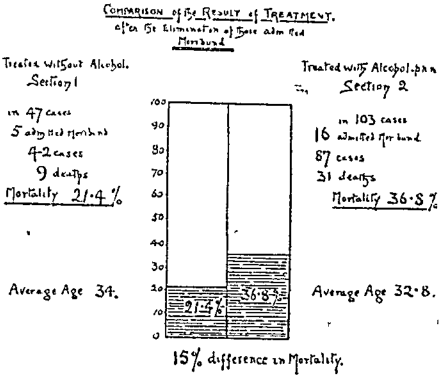
The 150 cases to which I have already referred and on which this paper is based are divided into two sections. The first is composed of 47 cases. These were not in any way selected. Every case that came in on certain days was included in this section and came more especially under my care. Throughout they received no alcohol. In the second section are included 103 patients who were admitted on the remaining days of the week and who were placed under the care of the other assistant medical officers. They received alcohol when the ordinarily accepted indications for its use arose. The patients in each section were of the same type, they were drawn from the same districts, and were attacked at the same seasons of the year. The nursing was much the same throughout the hospital and the food came from a common kitchen. Under such similar conditions if we find that any particular line of treatment gives exceptionally good results in a large series of cases one is justified, I think, in ascribing to it some proportion of the success. The result in these 150 cases was definitely, one might say startlingly, in favour of that treatment in which alcohol was not administered. It is a common saying that anything can be proved by means of statistics, but I am unable to see how the most ardent advocate of alcohol as a therapeutic agent can fail to be impressed by the result of withholding it in the above series of 47 cases. There is no desire on my part to juggle with figures. I have taken great care in drawing up these tables to eliminate every source of error and am content to allow the tables to speak for themselves. It has been put to me that possibly some of the patients in Section 1 might have been saved if only they had been given alcohol. That, of course, cannot be contradicted, and possibly if I were now to treat those cases there might be occasions on which I would exhibit alcohol following those indications for its use which I have laid down. As a matter of fact, however, practically all those conditions in which alcohol may be used can be efficiently met by other drugs. And for the purpose of comparing the results it was obviously wiser to eliminate alcohol entirely from the treatment.

TABLE I.



The tables have been drawn up to show at a glance the relative mortality in the two sections. Table I. shows a mortality of 29·5 per cent. occurring in those treated without alcohol as compared with 45·5 per cent. in Section 2, giving a difference in mortality of 16 per cent. This was such an astonishing difference that I thought it might possibly be due to a larger preponderance of patients admitted moribund into Section 2 than into Section 1. Table II. shows the result of eliminating from the statistics all those dying within 24 hours of admission. The mortality in Section 1 then becomes 21·4 per cent., and in Section 2 36·8 per cent.—a difference in mortality of 15 per cent. As the death-rate varies so much in the different age periods I have compared the two sections from this standpoint and find that before eliminating the moribund cases the average age in each section was 35 years, whilst after eliminating those dying within 24 hours of admission the average age in Section 1 was 34 years and that in Section 2 was 32·8 years. We note, therefore, a difference of 15 per cent. in the mortality remaining after the elimination of the moribund cases—the two sections having for all practical purposes the same average age. There may possibly be, and probably there are, several causes for this variation in death-rate. Chance itself may account for some of it, but the obvious and outstanding cause is the administration of alcohol in one section and its non-administration in the other, and I believe that it is this factor which is largely responsible for the difference in mortality.

TABLE II.



The drugs which we used in order to prevent or to counteract cardiac failure were practically four: strychnine, digitalis, caffeine, and ammonium carbonate. Strychnine and caffeine are recognised as good stimulating cardiac tonics. Digitalis is a more purely cardiac tonic. In the administration of strychnine one must be careful neither to begin too soon nor to give too large doses, for it must be remembered that there is only a certain definite reserve force in each heart that can be called upon. The main object must therefore be to spare the heart from every strain and only to use cardiac stimulants when absolutely necessary. Both strychnine and digitalis I preferred to administer hypodermically and when given in sufficient doses they will obtain from the heart a large proportion of its possible energy. In alcoholic cases more especially is it advisable to give digitalis hypodermically because, as O. T. Osborne[1] points out, digitalis is absorbed with great difficulty from the stomach in such patients. Digitalis slows the heart and simultaneously increases the force of its contraction, tending to raise the blood pressure by contracting the peripheral vessels.

As an example of the value of digitalis in contradistinction to alcohol in its action on the heart Sir Samuel Wilks relates a very suggestive case.[2] "A young lady, for many years the subject of mitral disease, had been for some time growing worse until at last she took to her bed" and he was asked to see her. "It was a matter of formality as she was thought to be dying. She was lying in bed gasping, with a fluttering heart and an almost imperceptible, irregular pulse, and semiconscious. She was being plied with brandy in order to keep her alive. The two medical men who were with her did not perceive that they were poisoning her but nevertheless assented to my strong wish to stop the spirit. This was done and 15 drops of tincture of digitalis were to be given every hour for a short time. After a few doses the frequency of the pulse was lessened. She breathed better and was more sensible. She then continued the remedy to a less amount. She rapidly improved."

---

[1] O. T. Osborne: What ought we to expect from Cardiac Drugs in Heart Weakness? Medical News, 1903, vol. lxxxiii., p. 541.

[2] The Practitioner, November, 1902.

Strychnine stimulates the cardiac centre, cardiac ganglia and nerves, and also in a marked degree the respiratory centre. One-fiftieth of a grain was given every four hours if any signs of cardiac exhaustion were observed and, if necessary, this dose was increased to $\frac{1}{25}$th of a grain. Both camphor and musk, more especially the latter, must be looked upon as valuable cardiac stimulants, but the cost of musk is so great that it was impossible to make use of it. If given at all, I am told by those who have exhibited it, doses of from five to ten grains should be administered every few hours. Ammonium carbonate has been found chiefly of use in those cases associated with bronchitis. It should be administered in large doses—ten grains every four hours and occasional doses of 20 or 30 grains in addition. It rarely produces emesis and is usually followed by very free expectoration. I first became convinced of the value of these large doses as an expectorant and cardiac stimulant in the case of a woman suffering from marked emphysema and bronchitis. She was propped up in bed, breathing rapidly, tossing about, distressed, and very cyanosed. Her heart was dilated and her pulse was irregular. Her lungs were full of râles and rhonchi. For some days she had been taking an ordinary expectorant mixture with very little benefit. I ordered her a half-drachm dose of ammonium carbonate, to be repeated in an hour if it had not produced emesis. Following the second dose she began to expectorate large quantities of muco-pus and was greatly relieved. Since then I have frequently tried these large doses and generally found marked benefit follow their exhibition not only in cases of bronchitis and emphysema but also in pneumonia associated with bronchitis in which the expectoration tends to be profuse and of a bronchitic character. Caffeine can be administered either as strong coffee or as the citrate. It acts as a stimulant, cardiac tonic, as a nervine tonic and also as a cerebral stimulant. This latter property would make one hesitate to give it when the insomnia is troublesome. Its action on the kidneys may help to eliminate toxic matters.

There is one form of treatment to which I would like to refer in conclusion—namely, the application of icebags to the abdomen so strongly recommended by Dr. Barr.[10] These were applied in some 20 cases and with benefit. The cold applied to the abdomen steadies the temperature and by acting on the splanchnic area improves the tension and volume of the pulse. It increases the depth of the respirations and thus greatly assists the heart by increasing the force of the respiratory pump. It also, according to some authorities, distinctly increases the value of digitalis in pneumonia by tending to bring the circulation into equilibrium.

If one determines to use the icebag it is most important that it should be firmly fixed, otherwise it will tend to slip down on to the groin and be a source of great discomfort. The sensitive groins should be protected with wool or lint. A medical man, a member of the Liverpool Medical Institution, has mentioned to me the comfort and benefit which he received from the icebag during an attack of pneumonia and he also referred to the discomfort which he experienced until his groins had been protected and the icebag firmly fixed in its correct position.

Liverpool.

FOUR CASES OF ACUTE INTESTINAL INTUSSUSCEPTION; OPERATION; RECOVERY.

BY F. C. WALLIS, F.R.C.S. ENG.,
SURGEON TO CHARING CROSS HOSPITAL AND TO THE METROPOLITAN HOSPITAL.

CASE 1.—The patient, aged two years and three months, was admitted to Charing Cross Hospital on Jan. 29th, 1903, [illegible] istory of abdominal pain of one week's duration. [illegible] ns were normal. The pain was paroxysmal. [illegible] be felt per rectum on admission but after an [illegible] nd mucus were passed.

Operation.—On the same day under chloroform a firm transverse tumour could be made out at the level of the umbilicus (nothing being felt before the anæsthetic owing to straining). After a two-inch incision above the umbilicus the intussusception was easily reduced; it was of the ileo-cæcal variety. There was slight œdema of the gut. The abdomen was closed in one layer. The operation occupied 12 minutes. Recovery was uneventful.

CASE 2.—The patient, a child, aged seven months, was admitted to the Metropolitan Hospital under my care on July 21st, 1903, with vomiting and collapse for one and a half hours. The pulse could hardly be felt and the extremities and nose were cold. Nothing abnormal could be made out in the abdomen. On the next day, vomiting continuing and blood being passed per rectum at 4.30 P.M. and 6 P.M., the presence of a swelling in the hepatic region was diagnosed and operation was decided on. The temperature was 103° F. in the morning.

Operation.—Under A.C.E. mixture the tumour was made out with ease and I opened the abdomen in the right linea semilunaris by a two-inch incision. The intestines were somewhat congested and distended and it was not found possible to get at the intussusception until the incision had been enlarged and the gut allowed to escape. This was protected by hot cloths and the intussusception (of the ileo-cæcal variety) being drawn up into the wound seven inches of invaginated gut were gradually reduced by combined pressure and traction. The invaginated gut was healthy but a good deal injected. The abdominal wound was closed by silk-worm gut through all the layers of the wall. On July 23rd some blood was passed by the bowel. The temperature sank to normal on the twelfth day, after removal of the stitches, and the child was discharged on August 8th. (N.B.—There were some vomiting and diarrhœa until August 2nd, when breast-feeding was resumed.)

CASE 3.—The patient, a child, aged 11 months, was admitted to Charing Cross Hospital under my care on April 20, 1903. The history was similar to that of the last case—viz., sudden onset of vomiting, paroxysmal pain, and the passage of blood and slime per rectum on the day of admission. The pulse was 160 and the temperature was 97·4° F. An elongated tumour was readily seen and felt in the left half of the abdomen, not very tender, hard, and slightly moveable.

Operation.—This was performed seven hours from the first symptoms and one hour from admission, under chloroform and later chloroform and ether, by median incision below the umbilicus. The tumour, which was easily hooked up by the index finger and readily reduced, was of the ileo-cæcal variety, the appendix appearing last. The operation lasted about nine minutes. The wound was closed by interrupted sutures. On April 23rd, after one drachm of castor oil, the bowels were opened twice; there was no blood or slime. On the 27th the stitches were removed. The patient was discharged in good condition.

CASE 4.—The patient, aged six months, was admitted into the Metropolitan Hospital under my care on June 27th, 1903, with a history of vomiting and much pain for one day. Blood and mucus came from the rectum and a sausage-shaped tumour was present in the right iliac region.

Operation.—Under chloroform an incision was made over the swelling in the right iliac region. The intussusception was ileo-cæcal and easily reduced. The abdomen was sutured in one layer. On June 28th there was acute bronchitis in both lungs which quickly cleared up. On the 30th the patient was much collapsed and had convulsions for four hours. On July 6th the stitches were removed. The temperature was normal on the seventh day. On the 17th the patient was discharged quite well.

These four cases were operated on as soon as the condition was recognised and no attempt to reduce the intussusception by any of the well-known methods was attempted. I have long been of opinion that such methods should not be attempted and *should not be taught*. It must be only in extremely rare cases, if ever, that any good is obtained by injections of water, gas, air, &c., and the usual results of this treatment are waste of valuable time, loss of vitality in the small patient, the possibility of a rupture of the intestine, a continuance of the symptoms, and of the condition of temporary starvation which exists in these patients and which is a serious factor in infants.

In two cases the incision was made in the right semilunar line and in the two others in the mid-line, this depending on the position of the intussusception. In all four cases the intussusception was lifted out of the abdomen, reduced, and returned. No attention was paid to the thickened and inelastic condition of the invaginated bowel—this rapidly recovers; the incision was sewn up with one set of sutures. The operation in Case 1 took 12 minutes; in Case 2 it took 15 minutes; in Case 3 nine minutes; and in Case 4 ten minutes. Feeding was commenced a few hours after the operation and recovery was uneventful in all the cases except in Case 4, which but for prompt treatment might easily have succumbed to an attack of bronchitis.

---

[10] Loc. cit.

Early diagnosis is an essential point for the successful treatment of these cases. It is not necessary to wait until a tumour can be felt. Vomiting and the passage of blood-stained mucus coming on suddenly in an otherwise healthy child are sufficient indications for an anæsthetic to be given. When the abdominal walls are thus relaxed any tumour formed by the intussusception can be readily felt and dealt with at once The dangers of waiting were exemplified in Case 2, where, because no tumour could be felt, nothing was quite a large one and had to be manipulated carefully during its reduction.

These cases emphasise the conclusions drawn by Mr. H. M. Rigby in his paper in THE LANCET of Feb. 7th, 1903, p. 364

Harley-street, W.

A CASE OF ACUTE INVERSION OF THE PUERPERAL UTERUS; REDUCTION BY TAXIS; RECOVERY.

BY E. OCTAVIUS CROFT, M.D. DURH., M.R.C.S. ENG.,
HONORARY SURGEON TO THE HOSPITAL FOR WOMEN AND CHILDREN, LEEDS; DEMONSTRATOR OF MIDWIFERY, UNIVERSITY OF LEEDS;

AND

ROBERT MUSCHAMP, L.R.C.P. & S. EDIN.

ACUTE inversion of the uterus is a condition which fortunately very rarely occurs. Dr. Robert Barnes[1] stated in 1885 that the accident had become so rare that many men of large experience had never seen it. In former days it was not uncommon and this may be said to be the case in countries where obstetric practice is largely in the hands of women. Let us now hope that eventually our efforts to improve the efficiency of midwives and the art of obstetrics generally may render it still more rare. Owing to the infrequency of the condition no useful statistics are available, but a number of cases have been reported and collected from time to time, especially abroad. The obviously dangerous symptoms of acute inversion are those of shock which is severe and uterine hæmorrhage, and from either or both of these conditions about one-third of the cases die. About three-fourths of the fatal cases die within half an hour. Of those who survive the immediate dangers nearly one-fourth die in the chronic stage, often when the re-establishment of menstruation leads to further hæmorrhage. Although generally due to faulty management of the third stage of labour there are doubtless certain abnormal conditions occasionally present under which the catastrophe may occur spontaneously.

For the opportunity of treating the following case, and especially for the trouble taken in obtaining a history of the accident, I am indebted to Mr. Robert Muschamp of Guiseley who was called in to see the patient and at once recognised the state of affairs and had the woman conveyed to Leeds to be placed under my care. The following is the history of the case so far as Mr. Muschamp had been able to get it from the midwife who was present at the confinement.

The patient, aged 28 years, married, was in her third pregnancy. Her first labour was instrumental and the second, which took place about two and a half years previously, was normal. On Jan. 19th, 1904, she did her day's washing and about 12.30 A.M. on the 20th she commenced with rather severe labour pains. The midwife was sent for and the child was born about 20 minutes after her arrival. The whole duration of labour was about six hours. The placenta came away without much pain 15 minutes after the delivery of the child and on the midwife slightly pulling the cord and asking the patient to cough. There was a free discharge, but, in the words of the midwife, "not what you would call a flooding." The patient, however, stated that she lost much more than she did at her previous confinements. The midwife felt the uterus before putting on the binder and it was, in her opinion, in its usual place and contracted. The binder was applied firmly. Immediately afterwards the patient was attacked by violent after-pains which continued all day. On the 21st she was easy but looked very pale and sickly. She remained in about the same condition on the 22nd. On the 23rd the bowels acted after half an ounce of castor oil. On the 24th she felt better and sat up in a chair for about ten minutes while the bed was made. She made no complaint of feeling faint and got back to bed all right. On the 25th she took a dose of liquorice powder, followed by one of castor oil and brandy. Early next morning (the 26th) she got out of bed and sat on the commode, when she had a great bearing-down sensation as though she wanted to relieve the bowels. At 6 A.M. she sent for the midwife and complained of something being down. On examination the midwife found a protrusion from the vagina to the extent of about an inch. She gently pressed this protrusion and it seemed to spring back. Mr. Muschamp was then called in by the midwife and he found the patient in a semi-collapsed condition, the temperature being subnormal and the pulse small and beating 120 per minute. On vaginal examination he found a fleshy and somewhat elastic tumour of about the size and shape of the lower three-fourths of a large Schweppe's soda-water bottle with the bottom rounded off and slightly flattened. The tumour was covered with tissue débris mixed with blood, &c., the whole giving off a very fœtid odour. On introducing his hand further—to where the neck of the uterus should have been had the tumour been merely a protrusion—he found the tumour practically continuous with the vaginal wall. The case was clearly one of complete inversion of the uterus and Mr. Muschamp at once sent the patient to the Hospital for Women and Children, Leeds, under my care.

On admission the patient was in a collapsed condition, the extremities were cold, and the pulse (126) was almost imperceptible at the wrist. The temperature was subnormal. There was very little hæmorrhage. The usual restorative measures were therefore adopted and it was thought wiser to allow the patient to recover a little if possible before doing any more. On Jan. 27th, being the eighth day of the puerperium and about 24 hours after admission, I made a careful examination. The abdomen was flaccid, not very tender, and easily palpated. No trace of the fundus uteri could be detected above the pelvic brim. On vaginal examination an offensive tenacious bloody discharge was noticed and a round swelling occupied the distended vagina, its lowest pole reaching to within about half an inch of the vulval outlet.

It was decided to attempt reduction with the aid of an anæsthetic. Mr. J. F. Dobson took the responsibility of the latter duty and I am specially obliged to him for his skilful help for reasons referred to later. The patient was placed in the left lateral position. After clearing away by douching and swabs the foul lochial discharge and débris which were present in the vagina and clinging to the surface of the tumour, I inserted my left hand completely into the vagina and satisfied myself that the mass was that of a completely inverted uterus and nothing else. There was no trace of a cervical ring, the neck of the uterus passing directly and smoothly into the vaginal fornices at the top of the pelvis. The surface of the mass was softish and of a pinkish colour, somewhat roughened and spongy, especially on its anterior aspect. This anterior portion also seemed rather more impressible and was no doubt the placental site. The right hand was then passed up above the pubes and a bimanual examination was made. No fundus uteri was detected anywhere except in the grasp of the left hand, but on pressing the fingers downwards in the hypogastric region the inverted cervix could be made out with ease and a finger could be inserted into the depression formed by the inverted structures. Owing to the contracted state of the uterus it seemed doubtful whether I should succeed in reducing the displacement by taxis or whether gradual methods would have to be adopted, such as elastic pressure by Aveling's or other procedures. I tried the former. The uterus was grasped in the left hand and gently compressed. The right hand was then used for counter-pressure above the pubes, the finger tips being so far as possible held in the form of a ring on the rim of the depression felt through the abdominal wall. The anterior part of the uterine wall was softer than the posterior and could be more readily indented. I took advantage of this and pressed this portion up with my thumb. As soon as a pouch was formed upwards in this part the advantage gained thus was maintained by the pressure of a gauze pad held in sponge forceps. A further portion of wall lower down was then pushed up and so on. The cervix was noted to yield as further portions bulged upwards into its canal. Ultimately the whole uterine and cervical walls were restored completely to their normal position, the last portion to return being the posterior lip of the cervix. Finally, I passed several fingers into the uterus as far the fundus and by internal and external manipulation made sure that the reduction was complete. Keeping the fingers in the uterus the cavity was freely irrigated with weak biniodide of mercury solution (1 in 5000) and finally packed from above down with iodoform gauze as the fingers were withdrawn.

---

[1] Obstetric Medicine and Surgery, vol. ii.

It is important to emphasise the fact that during the actual progress of replacement, which occupied some eight or ten minutes, the patient suffered severely from shock and at this time required very careful attention from the anæsthetist, Mr. Dobson. Saline infusion, hypodermic injections of strychnine, and other measures were required. When the operation was over the condition markedly improved.

On the day of the operation the gauze was removed and the uterus, which retained its normal shape, was irrigated with sterilised water and repacked. On the following day the gauze drainage was discontinued. The temperature rose to 101° F. on the second day but gradually settled and from the sixth day remained normal. The extreme anæmia was dealt with in the ordinary way and rapid improvement took place. The patient left the hospital on the sixteenth day after operation and on that day a pelvic examination was made. The uterus was apparently in a condition which could be described as normal for the third week of the puerperium. There was no displacement and the uterus was symmetrical and firmly contracted. The cervix was also normal.

Remarks.—The diagnosis of the case was definite and the result of treatment was satisfactory. The point of interest is as to when the inversion took place. Mr. Muschamp suggests that a partial inversion was produced during the removal of the placenta and that the inversion was completed by the contraction which followed during the period of severe after-pains. In support of this the history relates an artificial removal of the placenta; some pulling on the cord and voluntary coughing and straining; then a free hæmorrhage and for several hours violent after-pains; a few days afterwards rectal pressure symptoms and an attempt to relieve them by aperients. The symptoms became worse on purging and on straining at stool the fundus was forced through the vulva. This explanation seems to me entirely the correct one and I think it extremely unlikely that the inversion took place on the seventh day when Mr. Muschamp was called in.

KOPLIK'S SPOTS IN THE DIAGNOSIS OF MEASLES.

By J. C. MUIR, M.D. CANTAB.,
ASSISTANT MEDICAL OFFICER, PLAISTOW HOSPITAL.

IT will be readily admitted that in dealing with outbreaks of measles in a hospital or other institution one of the most important points is to make a definite diagnosis as soon as possible in every suspected case. The same is true in private practice if it be desirable and possible to shield from infection the younger or especially feeble members of the family. The comparatively slight attention paid to Koplik's spots in this country and the fact that they have even been regarded as of no great value must be my excuse for venturing to record so small a number of cases. I am indebted to Dr. J. Biernacki, medical superintendent of the Plaistow Hospital, for permission to publish them.

CASE 1.—The patient, a male, aged five years, was admitted for scarlet fever on Jan. 1st, the fifth day of the scarlatinal attack; the temperature, which had fallen to 99·8° F., rose to 102° without obvious cause. On the 2nd there was distinct broncho-pneumonia without other catarrhal symptoms. On the 4th the temperature was 103°. Koplik's spots were present; they were not looked for earlier. A diagnosis of measles was made and the patient was isolated. There were no distinct coryzal symptoms. On the 5th the rash was seen. This case is interesting as an instance of measles developing in the acute stage of scarlet fever.

CASE 2.—The patient, a male, aged four years, was admitted for diphtheria. On Dec. 31st the temperature, which previously had been normal, rose to 99·2° F. On the 2nd (the third day) he had slight cough. Koplik's spots were present but were not typical; on the 3rd they were distinct. A diagnosis was made and the patient was transferred to the measles ward. On the 4th (the fifth day) the rash developed.

CASE 3.—The patient, a male, aged three years, was admitted for diphtheria. On Dec. 31st the temperature was 102° F. at 11 P.M. On Jan. 3rd (the fourth day) Koplik's spots were present; they were not looked for earlier. A diagnosis was made and the patient was transferred to the measles ward. The catarrh was very slight. On Jan. 4th (the fifth day) the rash developed.

CASE 4.—The patient, a male, aged two years, was admitted for scarlet fever. On Jan. 2nd the temperature was 99° F. On the 4th (the third day) the rash and Koplik's spots were both present. The spots were not looked for earlier.

CASE 5.—The patient, a male, aged one year, was admitted for diphtheria. On Jan. 7th the evening temperature was 101° F. He had a slight cough and had sneezed. On the 9th the temperature was 100·2°. Koplik's spots were present (36 hours from the onset). The catarrh was very slight. A diagnosis was made and the patient was transferred to the measles ward. On the 11th (the fifth day) the rash developed.

CASE 6.—The patient, a male, aged five years, was admitted for scarlet fever. On Jan. 4th he had a slight nasal discharge. On the 7th the temperature was 100° F. On the 8th (the second day) spots were present, within 24 hours of the onset of the pyrexia. There was no catarrh. On the 11th (the fifth day) the rash developed.

CASE 7.—The patient, a female, aged five years, was admitted for diphtheria. On Jan. 10th the temperature was 98·8° F. in the morning and normal in the evening. On the 11th the temperature was 102° in the evening. Koplik's spots were present (second day). On the 12th (the third day) a slight and atypical rash was present. Catarrh was practically absent. On the 13th the rash was characteristic.

CASE 8.—The patient, who was a brother of the patient in Case 7, aged one year, was admitted for diphtheria. He was examined on Jan. 12th in view of the occurrence of the last case. He had very slight cough but no symptoms suggesting measles. The temperature had been 98·8° F. on the 10th but normal before and since. Koplik's spots were found on the 12th. He was isolated in the forenoon with a diagnosis of measles. In the evening the temperature rose to 100°. On the 13th the rash developed.

CASE 9.—The patient, a male, aged three years, was admitted for scarlet fever. On Jan. 17th the temperature was 99 8° F. On the 18th (the second day) spots were present though not well marked. On the 20th (the fourth day) the rash developed. The spots were now well marked.

CASE 10.—The patient, a male, aged two years, was admitted for diphtheria. On Jan. 22nd the temperature at 11 P.M. was 102·8° F. On the 24th (the third day) there were some doubtful spots; the catarrh was slight. On the 25th (the fourth day) the spots were distinct. The patient was transferred to the measles ward. On the 26th the catarrh had increased Late at night there were doubtful traces of rash. On the next day (the sixth) the rash was characteristic.

CASE 11.—The patient, a male, aged five years, was admitted for scarlet fever. On Jan. 24th the temperature was 100 6° F. On the 25th spots were present at 3 P.M. (24 hours from the onset) but were not well marked. At 11 P.M. they were quite well marked. A diagnosis was made. No catarrh was present. On the 28th (the fifth day) the rash developed.

Three other cases occurred before the above but were diagnosed and isolated without reference to the spots. In these 11 cases, in which the spots were definitely looked for, they were found in all, though in most larger recorded series there have been exceptions. Unfortunately, in the earlier ones the spots were not looked for sufficiently soon, but in those in which a systematic search was made their appearance was never delayed beyond the third day of pyrexia and occasionally they were seen within twenty-four hours of its onset. The interval from their appearance to that of the rash varied between one and three days. Except in Case 1 the temperature was previously normal or subnormal, so that the onset could be accurately dated. In Case 6 there was slight nasal discharge for three days with normal temperature; in all the others pyrexia was the earliest symptom. Case 8 is specially interesting as it presented no symptoms suggestive of measles and was only examined for the spots on account of the relationship to Case 7. In almost all the cases the prodromal catarrh was very slight, a fact which enhanced the value of the spots. In some of them it is not too much to say that a certain diagnosis was impossible, at that date, apart from their presence. I had not at first the courage to put a child into a ward with other cases of measles on the strength of the spots, with only slight (and in itself insufficient) collateral evidence of infection. Latterly, however, I did so, and in no case did the rash fail to develop. Cases of pyrexia in other conditions, such as serum rash, broncho-pneumonia, and the like, were carefully examined, but only once did I find any condition which could not, with care, be differentiated from the spots. The case was one of diphtheria in which there occurred one evening a temperature of 102° F. with cough. On examination I certainly thought I saw two or three Koplik's spots and had the patient placed in a ward by himself. Next morning, however, there was no trace of the spots nor did they subsequently develop. The cough proved to be the earliest symptom of a severe attack of diphtherial paralysis. It may be said, then, that making allowance for the shortness of the series, it bears out the conclusion of most writers that Koplik's spots are of much value in the *early diagnosis of measles*. Other symptoms which will usually be present and may even occur before the pyrexia must not be neglected. It is where these other symptoms are slight and inconclusive as in some of the above cases, that the presence of the spots may decide the diagnosis. They are absent in, roughly, 10 per cent. of recorded cases.

Plaistow, E.

A CASE OF RENAL ABNORMALITY.

By RUPERT BUTTERWORTH, M.B., B.C. CANTAB.,

HOUSE PHYSICIAN AT THE DERBYSHIRE ROYAL INFIRMARY, DERBY.

BY the courtesy of Dr. E. Rice and Mr. R. H. Luce, under whose care the patient was while in the Derbyshire Royal Infirmary, I am enabled to report what I hope may be considered an interesting abnormality.

A man, aged 34 years, was admitted into the infirmary on May 20th, 1904, with a history of hæmatemesis and he was said to have had some fits the precise nature of which could not be ascertained. There was no history of any renal trouble. He was obviously very ill and died a few hours after admission. No hæmatemesis occurred nor did he have any fits during that time. He was somewhat comatose and there was some bleeding from his gums. His tongue was not bitten.

At the post-mortem examination it was found that there were miliary tubercles along the meningeal blood-vessels, there being fairly large aggregations in some places. They were chiefly on the vertex and comparatively scarce at the base. There was congestion of the blood-vessels of the left occipital lobe. The lateral ventricles were considerably dilated. The upper lobe of the right lung was shrunken and airless, the bronchi being hard and dilated. There were no cavities or scars. The bronchial glands were calcareous. The stomach was distended with fluid but contained no blood. There was congestion of the veins at the cardiac orifice.

The interest of the case consisted in the fact that there was only a single kidney, firmly fixed, situated in the middle line. The upper end just overlapped the bifurcation of the abdominal aorta and the main portion lay between the two common iliac arteries. It rested on the fourth and fifth lumbar vertebræ and the upper segment of the sacrum. It was approximately of the size of a normal kidney, if anything slightly smaller. As I wished to send it intact to the St. Mary's Hospital Museum, London, I did not separate it from the ureter to weigh it. For the same reason I did not cut it and I am indebted to the curator, Dr. J. F. H. Broadbent, for the description of the kidney on section. In shape it was lobulated and broader at the upper end than at the lower. The renal artery came from the right common iliac. On section Dr. Broadbent states that he found a considerable degree of hydronephrosis with chronic thickening of the calices and connective tissue framework with atrophy of kidney tissue of which there was very little remaining. There was a single ureter six inches in length. It rose from the posterior aspect of the kidney low down. Its lumen was very large, averaging three-quarters of an inch. There was a constriction just before it entered the bladder, into which it opened by a single orifice in the middle line. There was no stone found or any reason to believe that the dilatation was other than congenital. The bladder wall was normal. The rectum crossed the single ureter almost at right angles and dipped down into the pelvis on the right side of the bladder—a curious relation, but it did not appear to have exerted pressure on the ureter.

The whole condition is perhaps more interesting from a surgical than from a medical point of view, although it seems extraordinary that the small amount of kidney tissue was sufficient, and should such an abnormality occur in a woman it would be a possible cause of obstructing labour by diminishing the conjugate.

Derby.

AN UNUSUAL CASE OF MUSCULAR ATROPHY.

By W. LANGDON BROWN, M.A., M.D. CANTAB., M.R.C.P. LOND.,

ASSISTANT PHYSICIAN TO THE METROPOLITAN HOSPITAL; JUNIOR DEMONSTRATOR OF PRACTICAL MEDICINE, ST. BARTHOLOMEW'S HOSPITAL.

THE following case of progressive wasting of the muscles of the shoulder girdle which I have had under observation for two and a half years presents some unusual and interesting features.

The patient first came under my care in November, 1901. He was then 13½ years of age. He was said to have lost power in the left arm at the age of five months. Since that time the left arm had always been smaller than the right but there had been no progress in the wasting till one year ago. One brother had died in an asylum, otherwise there was nothing in the past history or family history bearing on the case. At first sight the diagnosis seemed to lie between old infantile palsy or Erb's juvenile paralysis. The history was untrustworthy, so that it was difficult to estimate how much of the wasting was recent and how much of it was old. But the fact that the left arm, measured from the coracoid process to the styloid process, was an inch shorter than the right showed that some of the wasting must have been of long standing. Yet a response was elicited from all the muscles both to the cell and to the coil currents. This made it look very like a myopathy, but there were two points strongly against this: (1) the affected muscles showed marked fibrillary tremors; and (2) the grouping of the muscles was quite different from that found in the myopathies, as the following table shows:—

Erb's type.		*Present case.*	
Biceps	atrophied.	Deltoid	Completely atrophied.
Triceps		Supraspinatus	
Supinator longus		Infraspinatus	
Deltoid	natural.	Biceps	Partially gone.
Supraspinatus		Triceps	
Infraspinatus		Pectorals	
		Supinator longus	natural.

In all other respects the boy appeared normal and in good general health. In 1902 the right side began to get weak also and fibrillary tremors were noticed on this side. In October, 1902, he was admitted to the National Hospital for the Paralysed and Epileptic, Queen-square, under the care of Sir William Gowers; the registrar has kindly informed me that the opinion formed at that time was that the boy had infantile palsy with doubtful muscular atrophy occurring subsequently. I did not see him again till the end of 1903 when I was struck with the increased loss of power in the left arm and the wasting of the left hand. It was stated that he had begun to have fits of unconsciousness during which he struggled and occasionally passed urine, but this was never seen during his stay in the Metropolitan Hospital where he was under my care from Feb. 29th to March 21st, 1904. His condition on admission was as follows. He was a healthy looking lad, 16 years old. His arms were very thin, especially the left. On this side the deltoid was almost absent, the head of the humerus, the acromion, and the coracoid process being very distinctly seen. The supraspinous and infraspinous fossæ did not appear to be occupied by any muscle at all. The trapezius was present but not well developed. There was very little of the pectoralis major remaining. The biceps and triceps were much wasted. In all these muscles fibrillary tremors were to be seen. There was no noticeable wasting of the muscles of the forearm. The thenar eminence of the hand was flattened and the interossei appeared to be slightly wasted. Formerly he could raise the left arm above the head without much difficulty; now he had to adopt the following complicated manœuvre. The upper arm was first approximated to the chest and the scapula fixed. The forearm was then flexed and finally the whole arm was raised by simultaneous extension of the forearm and rotation of the shoulder forward. On the right side the supraspinatus, infraspinatus, and deltoid were all slightly wasted and showed fibrillary tremors. The muscles of the abdomen and legs were not wasted. The knee-jerks were normal, there was no spasticity, the gait was not affected, and no disturbance of sensation could be discovered. The electrical reactions tabulated below were very different from those obtained in 1901:—

Left Side.—I. *Responding neither to Cell Current nor to Coil Current.*

	Spinal origin.
Deltoid	4th and 5th C.
Supraspinatus	4th C.
Abductor pollicis	8th C. 1st T.
Lumbricales...	
Interrossei (except fourth palmar)	

II.—*Not Responding to Coil Current, Sluggish to Cell Current.*

	Current in milliampères.	Spinal origin.
Fourth palmar interosseous	14	8th C. 1st T.
Adductor pollicis	13	
Infraspinatus	12	4th C.
Supinator longus	10	5th C.

III.—*Responding to Coil Current, somewhat Sluggish to Cell Current.*

	Current in milliampères.	Spinal origin.
Pectoralis minor	10	7th C.
Biceps	8	5th and 6th C.
Triceps	8	6th and 7th C.

IV.—*Reacting readily to both Currents.*

	Current in milliampères.	Spinal origin.
Pectoralis major	6	6th and 7th C.
Trapezius	6	2nd and 3rd C.
Extensors and flexors of forearm	6	6th and 7th C.

Right side.—All responded to cell current though the infraspinatus required a current of more than 15 milliampères and all responded to coil current.

That the condition is a progressive one there can now be no doubt. The increased loss of power is well shown by the difficulty experienced now in raising the arm, the increased wasting is seen in the intrinsic muscles of the hands, and the increased degeneration is amply attested by a comparison of the electrical reactions in 1901 and 1904. Old infantile palsy cannot account for these facts, especially as fibrillary tremors can now be seen on the right side. Erb's juvenile type of muscular dystrophy is negatived by the distribution of the wasting and by the disappearance of coil current excitability in certain muscles without loss of cell current excitability. Moreover, fibrillary tremors do not occur in myopathies. There remains the spinal type—chronic anterior poliomyelitis. Looking at the spinal representation of the muscles involved we see that the fourth, fifth, and eighth cervical and first thoracic segments are most affected, while intermediate segments, the sixth and seventh cervical, show less degeneration. And the degeneration in the lowest segments is quite recent. Beevor in Allbutt's "System of Medicine" points out that progressive muscular atrophy begins either at the upper or lower end of the brachial enlargement of the cord, while the part corresponding to the sixth cervical escapes. The grouping, then, of the affected muscles, the total absence of electrical response in some of them, and the reaction of degeneration in others, together with the presence of fibrillary tremors, seem to make it certain that chronic anterior poliomyelitis exists in this case. The history and the defective development of the humerus on the left side point also to an old acute anterior poliomyelitis. But if we take this view there are three unusual features in the case. 1. It is most exceptional for acute anterior poliomyelitis to become chronic. All the damage which is going to be done is usually done at once. And in this case there was an interval of about 12 years before the lesion became progressive. 2. Chronic anterior poliomyelitis is not a disease of youth. Beevor states that it rarely occurs before 25 years of age, though a case has been recorded in a child, aged one and a half years (Thomson and Bruce). 3. Chronic anterior poliomyelitis usually shows itself first in the small muscles of the hand. Here the shoulder girdle was attacked first, though the more ordinary procedure is being followed now, for the intrinsic muscles of the hand are degenerating faster than those affected earlier. Perhaps the previous attack of infantile palsy determined the onset of the progressive muscular atrophy in an area already damaged.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF "LATENT" PNEUMOTHORAX.

BY RICHARD BEVAN, L.R.C.P. LOND., M.R.C.S. ENG., D.P.H.

THE description of a case of pneumothorax recorded in a recent number of THE LANCET by Mr. E. F. Coghlan[1] has prompted me to put on record the notes of a case of so-called "latent" pneumothorax which recently occurred in my practice and in which the rapidity and completeness of the patient's recovery were as remarkable as they were in the case referred to.

On Sunday, Feb. 28th, 1904, I was sent for to see a young man, aged 24 years, a clerk in an office, who until the previous Friday morning had enjoyed the most robust health. As a proof of this he assured me that although he had been in his present situation for six years he had been absent for one day only during that period on account of sickness and that was for a severe cold in the head. He gave the following history. On Thursday afternoon after finishing his day's work he wished to put away a large pile of heavy ledgers on which he had been working. In height these, when being carried, extended from his chin to the length of his outstretched arms. His usual practice was to get his fingers underneath the pile, to tip them, and to allow them to fall bodily on to his chest. There was no lifting as the ledgers when resting on the desk were on a level with his chest. He had performed the same manœuvre scores of times without ill effects and he at the time felt none on this particular occasion. Being anxious to have some exercise after his day's work he walked from his office home, and no pain or discomfort or difficulty in breathing made its appearance before retiring for the night, except a feeling of extreme coldness. On waking in the morning and endeavouring to get up he experienced much difficulty in breathing, the sensation being, he said, as if one lung was solid and useless. The dyspnœa and distress were much increased later and especially on any movement, yet he determined to go to the office. During the whole day he felt very ill and thought that he had pneumonia or some acute lung trouble. On Saturday he remained at home, any movement causing him extreme breathlessness, but on the other hand while lying flat on his back and remaining quiet he had no pain and the urgency of the breathing was relieved. This made him hope that the attack would pass off. On Sunday, however, I was sent for. He was up when I saw him and his condition was as follows. While he was lying quite still there was not much apparent distress, his respirations being 32 per minute, his pulse 124, and his temperature 97·8° F. He was a healthy-looking [illegible] eight, well nourished [illegible] pounds. On examin- [illegible] walls was observable on the left side and the intercostal spaces were widely distended. On palpation no vocal fremitus could be obtained either in front or behind and the percussion note on that side was so absolutely dull and muffled in tone as to make me at first believe that the left pleural cavity contained fluid. The dull note extended evenly all over the front and back and no heart impulse was anywhere on that side observable. On auscultation no breath sounds or vocal fremitus could be heard at the back or front, but at or about the fifth intercostal space in front there was to be heard on inspiration a peculiar metallic sound which it is difficult to describe accurately, but which resembled in a marked degree the peculiar metallic spring-like noise which is made by my collar stud (which has a moveable head on a spring attachment) when I move my head. This sound, I may here remark, ceased on the third day of my attendance and was, I suppose, due to the escape of a minute bubble of air from the valvular opening in the lung and its bursting in the pleural cavity. On examining the right side of the chest the heart apex was discovered at a point in the fifth interspace about one inch beyond the right border of the sternum. Over and around this position the heart sounds were fairly audible. With this exception the physical signs on the right side were normal, the dividing line between the two pleural cavities being easily mapped out by the percussion note and the presence and absence of vocal resonance. The bruit d'airain was absent. The patient was simply kept quiet in bed for the first fortnight. He had no pain or dyspnœa and he slept and ate well. On the third day of my attendance the extreme distension of the left side had lessened perceptibly and the percussion note for the first time became markedly hyperresonant all over, including, of course, that portion of the left side usually occupied by the heart. From the first he gradually got better; the heart beats lessened in frequency, the tension in the chest lessened, the heart gradually moved over to its proper position, and the breath sounds returned, first at the apex in front and then gradually lower and lower; the difference in the vocal resonance on the two sides became less and less marked as the lung became less compressed by the absorption of the contained air until at the end of eight and a half weeks (April 28th), when I examined him carefully before letting him go for change of air prior to going back to work, no abnormal symptom could be discovered. He never at any time had any cough. His temperature never rose above [illegible] uring the illness able [illegible] in the pleural cavity. [illegible] He returned to work after a fortnight's change well and strong.

---

[1] THE LANCET, April 16th, 1904, p. 1052.

With regard to the cause of this accident, although an interval of some hours elapsed between what was the apparent cause and the effects, yet there is no doubt in my mind that the blow or weight on the chest by the ledgers was the direct cause. The leakage of air was so very gradual, the opening being minute and probably valvular, that it is impossible to say at what moment physical signs could have been discovered if they had been looked for. Distress did not arise until compression of the lung had become extreme. It has been argued by the office in which he was insured that he *ought* to have felt the symptoms sooner, but when in bed lying quietly on his back he never during the whole course of his illness had the slightest pain, distress, or dyspnœa, so that physical signs probably existed long before they were apparent to him. With regard to the mode of causation, we have first a deep inspiration filling out the chest cavity to the lung's utmost capacity and closure of the glottis, the lower edge lying between the chest wall behind the sixth rib and the firmly contracted diaphragm. Suddenly the patient has a smart blow from the heap of ledgers falling on to his chest wall, bending in the sixth rib, and possibly nipping or forcibly compressing the edge of the lung and rupturing a minute air vesicle. M. Gosselin even says that the prolonged compression of the over-distended lung will cause it to give way, the glottis being tightly closed. The analogy has been suggested of a bit of the inner tube of a bicycle being accidentally nipped between the wire of the outer casing and the rim of the wheel when not properly returned after mending a puncture, &c., and rupturing the tube directly the rider mounts and puts pressure on the tube. It has been suggested, too, that in most if not all of these cases of pneumothorax occurring in the apparently healthy some previous disease, probably tuberculous softening, has conduced to bring about the result Here we have no family or previous personal history which would lead one to suspect it, and the complete recovery of the patient tends to nullify any such supposition; besides which the history of the accident would to my mind be quite sufficient to account for the damage to the lung without there being any necessary previous disease, while finally the absence of any effusion or pleurisy tends to confirm my contention of its absence.

West Kensington, W.

PTOMAINE POISONING FOLLOWED BY DESQUAMATION.

BY PERCY T. GOODMAN, L.S.A. LOND.

ON May 20th, 1904, I was called in the early morning to a family of seven persons who had all partaken of a fish supper on the previous evening. They were in a state of collapse, with pallid faces, clammy perspiration, and cold extremities, and were complaining of severe abdominal pain and vomiting. In two cases diarrhœa was present with very offensive stools. There was no urticaria or rash of any description. None of the family had any rise of temperature or sore-throat. Warmth was applied to the extremities and a purgative was given followed by stimulants (ammonia and ether). All the patients recovered and I saw nothing more of them until June 1st when the mother brought one of her boys to me on account of his school teacher having sent him home because of the condition of his hands and feet from which the skin was coming off, chiefly on the palmar surface, in large flakes. The mother also had some slight desquamation on the forearms. I went to the house and saw the other children whose ages ranged between seven and 16 years, all of whom had the same curious desquamation on the palms of the hands and the soles of the feet. The father alone was not affected in this manner.

I have heard of one other similar case which occurred in the practice of my friend Dr. J. Snowman of Brondesbury, but I do not remember having anywhere read an account of this remarkable condition after food poisoning. The points of interest in these cases lie in their strong resemblance to post-scarlatinal desquamation and in the fact that six of the seven persons who suffered from ptomaine poisoning developed this unusual sequela.

Spitalfields, E.

SEQUEL TO A CASE OF INOPERABLE CANCER TREATED BY OOPHORECTOMY.

BY WALTER EDMUNDS, F.R.C.S. ENG.,

SURGEON TO THE TOTTENHAM HOSPITAL

IN THE LANCET of March 29th, 1902, at p. 888 is recorded a case of scirrhus of the breast in which symptoms of intrathoracic growth appeared five years after amputation. There was also a recurrence in the remaining breast. Oöphorectomy and thyroid feeding were had recourse to, with the result that at the time of the report, a year after the operation, the patient was much better. The tumour in the breast and axillary glands had almost disappeared and the dyspnœa, too, had nearly gone. The further history of the case is that nine months later the patient was not so well: the tumour in the breast had somewhat increased and was commencing to involve the skin; the dyspnœa, too, was somewhat worse. Three months later the skin over the tumour had ulcerated and on this account it was thought advisable to amputate the breast. Unfortunately the patient died from heart failure while under the anæsthetic. An account of this part of the case has already been placed on record by the anæsthetist.[1]

A post-mortem examination was made by Dr. L. Freyberger at which he invited me to be present. The right breast was as described; there were also enlarged glands in the axilla and recently infiltrated glands in the flank. At the bifurcation of the trachea was a mass of secondary growth involving the roots of the lungs. The left lung was bound to the chest wall by old adhesions, the aorta was atheromatous, and the heart had undergone some fatty degeneration. Although the oöphorectomy did not save the patient's life it produced for a time great benefit; the tumour in the remaining breast almost disappeared, while the small growth behind the ear did completely disappear; the symptoms due to the intrathoracic growth were also greatly relieved. In this case then, as in many others, much good was done by the operation. In conclusion, it may be pointed out that any theory as to the pathology of cancer must explain the improvement effected by oöphorectomy in recurrent scirrhus of the breast.

GREAT NORTHERN CENTRAL HOSPITAL.

A CASE OF SARCOMA OF THE PLEURA AND LUNG WITH CONSECUTIVE PERICARDITIS AND GROWTH IN BRAIN AND PANCREAS, PRESENTING UNUSUAL CLINICAL FEATURES.

(Under the care of Dr. H. W. SYERS.)

THE patient, a man, aged 31 years, married, was admitted into the Great Northern Central Hospital on Sept. 3rd, 1903, complaining of pain in the abdomen, headache, and malaise. He was in his usual health until the last week of the previous April, when he complained of feeling giddy from time to time. On May 14th he fell a distance of four feet on to a mound of soft earth. From this time onwards he complained of headache, backache, and of pain over the upper portion of the abdomen. At the beginning of June he first noticed that his eyesight was not so good as formerly and on several occasions he "saw double." At the same time some slight swelling of the face was noticed. There had been no swelling of the lower extremities or under the eyes; no vomiting, shortness of breath, cough, or jaundice had been complained of. Seven years before the patient suffered from rheumatism but the illness did not seem to have been serious. One and a half years before admission he had an attack of pleurisy affecting the left side, but was in bed one day only. There was no history of "fits" and none of alcoholism. Apart from the maladies mentioned he always appeared to have had very good health and there was no history of syphilis. The family history was unimportant. The patient was thin and rather pale. He complained of headache, not localised, and of failing eyesight, together with more or less generalised and indefinite pain, which was not, however, severe. The temperature was normal, the pulse was 96, and the respirations were 24; the tongue was clean. The lungs were healthy, except that at the left base there was dulness on percussion, extending nearly to the angle of the left scapula, and over the dull area the breath sounds were very feebly audible. The vocal resonance and vocal fremitus were both greatly diminished. In fact, there were the ordinary signs of a moderate pleural effusion at the left base. No adventitious sound could be detected in this locality. The heart was acting in an extremely forcible manner, so much so that the heart impulse, which was greatly diffused, could be seen at some distance from the bed and this even when the bedclothes were stretched over the chest as the impulse was sufficiently vigorous to raise them. The maximum impulse was in the fifth interspace and in the nipple line. No thrill could be detected on palpation. There was no murmur at the apex, but a rough systolic murmur could be detected at the second left interspace close to the sternum. The carotids did not pulsate unduly. Examination of the abdomen, and more especially of the epigastric region, revealed nothing abnormal. There was no paralysis, either general or special. Both knee-jerks were absent. A flexor plantar reflex could be obtained. These was no anæsthesia anywhere. The gait was somewhat unsteady and when he stood with eyes closed and feet together he began at once to stagger. There was slight undue prominence of the right eye but it was not certain that this had not always been the case. The pupils were equal and acted both to light and accommodation. There was no special peculiarity as regards speech. Most marked double optic neuritis was present, the lesion being especially prominent on the left side. The urine had a specific gravity of 1010; it was acid and contained neither albumin nor sugar.

On Sept. 8th it was reported that the patient had been restless and uneasy, especially at night. At times he seemed to lose consciousness momentarily and occasionally for longer periods. While unconscious he fell out of bed on two occasions. There was complete control of the sphincters. The violent action of the heart continued and was indeed more marked; the pulse-rate varied from 80 to 90. There were no fresh physical signs on auscultation either of the heart or lungs. On the 9th the condition was unchanged, except that the patient was less restless. The tendency to lose himself mentally was less marked. On the 14th a loud, harsh, pericardial friction sound was detected, loudest at the base and down the right margin of the sternum. There was no pain in the præcordial region and the temperature remained practically normal. On the 15th there was very obvious pericarditis; the apex beat was felt in the fifth interspace, half an inch internal to the nipple; it was diffuse and very forcible, raising the chest wall. No thrill could be detected. The dulness at the base of the left lung had now become absolute, and over this area the heart sounds were heard with unnatural clearness. The breath sounds were now completely absent over the dull area which extended upwards almost to the root of the lungs. The knee-jerks were still absent and irritation of the soles of the feet caused no extension of the toes. There was no paralysis or even paresis and no anæsthesia could be made out. The pupils remained equal and active both to light and accommodation.

The patient's mental condition now showed a change. He had been throughout rather silent and indifferent as to his condition, but by this time, although perfectly intelligent and readily responding when spoken to, he manifested a marked loss of initiative. He never asked for anything, showed no likes or dislikes, and made no complaint of any kind. He was not dull or lethargic, for when addressed he invariably answered clearly and to the point. The optic neuritis was, if anything, still more marked but he could see to read, though he never read a book or a paper voluntarily, remaining perfectly quiet in one position for hours together. On Sept. 19th it was noticed that the right eye was slightly more prominent than the left. The pericarditis persisted, the double friction sound being very well marked; the cardiac dulness now extended to the right border of the sternum. Nothing abnormal could be detected on examination of the abdomen, but during the next few days there were some pain after eating and flatulent distension. On the 24th he complained of severe pain in the upper portion of the abdomen, the pain extending through to the back. The pain prevented him lying down in an easy posture. He was now getting thin and the expression was worn and anxious. On the 28th the abdominal pain continued. The dulness over the left base was now increasing both vertically and towards the lateral region. On this day and on a previous occasion an exploring needle was passed into the area of dulness but neither fluid nor pus was withdrawn. On the second occasion some bright red blood entered the cavity of the syringe, but a small quantity only. On the 29th the cardiac dulness was increased in all directions, extending upwards to the left clavicle and one and a half inches beyond the right border of the sternum, and at the same time the friction sound disappeared, except at the left base, where it was faintly audible. The excessive activity of cardiac action vanished with the full evolution of the pericardial inflammation, and with the onset of fluid effusion the apex beat became invisible and could not be located by palpation.

---

[1] Transactions of the Society of Anæsthetists, vol. vi., p. 66, 1903.

In the course of the next six days the effusion was absorbed, the apex again becoming visible and palpable and the double friction sound returning over the whole præcordial region. During the same period, too, the dulness over the back of the left side of the chest greatly increased, nearly attaining the apex of the lung.

The patient was now losing flesh rapidly and had much gastric pain, worse after eating. At the beginning of October a mass could be felt in the epigastric and left hypochondriac region, the tumour being of about the size of an

ge of the liver could
the left lobe could
st referred to. The

temperature now became subnormal and remained so until the end. Rapid emaciation set in but the pain in the epigastrium and the occasional sickness from which he had suffered disappeared. The emaciation progressed and death ensued from asthenia on Oct. 10th. The same mental condition continued until the last, the patient being calm, placid, and altogether lacking in initiative throughout. There was practically but little evidence of lung trouble during the whole course of the illness. In the earlier stages there were occasional cough and expectoration; the latter contained no tubercle bacilli. There was no hæmoptysis at any period of the illness.

Necropsy.—The post-mortem examination was made the day after death. Rigor mortis had passed off. The body was extremely emaciated. A large, very hard mass could be felt through the abdominal wall in the epigastric and left hypochondriac regions. On opening the cavity of the thorax the left lung was found to be strongly adherent to the parietes over its lower lobe, so that some force was required in order to remove the organ and fragments of the lung were left adhering to the chest wall. There was a similar firm adhesion to the diaphragm on the part of the same lung. It was found on examination that the left lung was the seat of a new growth which also involved both the parietal and visceral pleura adjacent to the organ The left

wth,
the
n in
ened

the pleura to the extent of half an inch. The posterior mediastinum was full of the growth which had extended forwards towards the heart; it had attacked both the pericardium and muscular wall of this organ. The posterior portion and a large extent of the anterior surface of the pericardium were infiltrated with the growth and elsewhere there were the usual appearances indicative of acute pericarditis—much roughened lymph and loss of polish of the serous membrane. There was scarcely any fluid in the pericardial cavity, the pericarditis evidently being in an advanced stage of retrogression. The wall of the left auricle was practically replaced by new growth, for the muscular fibres were almost entirely destroyed by the malignant invasion. The wall of the left ventricle was also infiltrated but its muscle was fairly sound. The valves were healthy. In the upper portion of the abdominal cavity a mass was found as large as the closed fist. This was found to consist of the pancreas and neighbouring lymphatic glands. The head and two-thirds of the body of the pancreas were infiltrated with a new growth similar to that which was present in the left lung. The glands were enlarged and full of the same new growth. No other abnormalities were found as regards the abdominal cavity. The right cerebral hemisphere was the seat of new growth. This was situated in the corona radiata in the posterior portion of this structure but entirely removed from the motor tract. The mass was of the size of an orange, almost circular in outline, and soft in consistence. Its edge was well defined from the surrounding healthy white substance. The growth did not involve the grey matter of the cortex or the basal ganglia.

Microscopic examination of the new growth proved it to be a round-celled sarcoma with a few spindle celled elements.

Remarks by DR. SYERS.—The points of interest in this case concern the pulmonary symptoms, the physical signs at the earliest stage of pericardial involvement, the mental condition, and the locality in which the new growth originated.

First as regards the pulmonary symptoms. Although the physical signs of lung affection were so marked hardly any symptoms accompanied them. Occasionally there was complaint of cough but this was never troublesome or of long duration. Expectoration was trifling in amount and there was no hæmoptysis. It is certainly remarkable that with such extensive involvement of the lung little or no symptomatic evidence of the disease—cough, fœtid expectoration, hæmoptysis—should have been present. Pain in the chest was never a prominent symptom, and was, indeed, hardly mentioned.

A few days after admission the excessive over-action of the heart became extremely obvious; it increased from the time of admission although the patient was quietly resting in bed. As mentioned in the history of the case, the action was so violent that the elevation of the bedclothes was obvious to the bystander. At this time there was no friction sound to be heard and it was not possible satisfactorily to account for the extraordinary energy of cardiac action. It was thought that the undue extent occupied by the apex beat and the over-action of the heart generally might be the result of pressure from behind, and to a certain extent this explanation is justified by the post mortem findings as the heart was certainly projected forwards by the malignant disease which involved the left lung. But there can be little doubt that the most efficient cause of the cardiac excitement was the commencing involvement of the pericardium and of the muscular wall of the organ in the new growth. It would seem that the heart by every means in its power resisted the insidious approach of the malignant invasion which, however, only too rapidly gained the mastery. When the heart was surrounded with new growth and infiltrated with it the excessive activity of the organ ceased, and with the onset of abundant pericardial effusion its action became distinctly weak.

It is seldom that the opportunity occurs of watching the very earliest onset of a malignant pericarditis and carditis, and it is therefore of interest to note the extraordinary irritability which the heart displayed at the commencement of such an invasion of a previously healthy organ, but not until several days after the phenomena had been in existence was the first very faint pericardial friction sound audible.

The mental condition of the patient was interesting throughout. During the first few days after admission he was somewhat restless, sleepless, and excitable, occasionally getting out of bed and being inclined to walk about the ward. But very soon this excitable state ceased and he gradually passed into an apathetic condition, though perfectly cognisant of all that was passing. He retained his intelligence, knew his wife and friends, and did not seem to have lost his memory, yet he manifested not the slightest power of initiative, never asked for anything, never complained or grumbled, and always responded when spoken to quite clearly and intelligently. He was most amenable in every way and yet there was obviously some great mental change which can be best described as consisting in an entire want of the power of initiative.

At no period of the illness was there any paralysis, either hemiplegic, paraplegic, or local. And so far as could be made out there was no loss of sensation, either general or special, except as regards eyesight, which was distinctly defective. The patient was in no sense emotional. There was no attack of convulsions or of loss of consciousness except on the one or two occasions referred to in the history.

Lastly, as regards the locality in which the new growth originated. There can be little doubt that the point of origin of the sarcomatous growth was the left pleura and lung, and that the involvement of the pancreas was secondary. Clinically, at all events, the case was one of pulmonary malignant disease, for the physical signs were perfectly obvious in the left chest when the patient was admitted, at a period when physical examination of the abdomen gave completely negative results. It was only after he had been nearly a month in hospital that a distinct tumour in the epigastric region was detected, although for some short time previously there had been complaint of pain after eating. Sickness was only occasional but the pain was severe and it was necessary to resort to rectal feeding for some days.

Sarcoma of the pancreas is far from common and it certainly seems that the pancreatic involvement was secondary, and this both on clinical grounds as well as from the doctrine of chances. Infection of the pancreas and glands took place no doubt through the diaphragm which was practically the only barrier between the growth in the lung and the abdominal structures which were affected. As regards the cause of the malady the history is as usual silent, for it is tolerably certain that the slight fall which took place shortly before the illness commenced can in no sense be looked upon as in any way connected with the occurrence of the disease.

To Mr. G. A. Upcott-Gill and Mr. A. de Morgan, house physicians, my thanks are due for the notes of this case, and I am indebted to Mr. Allan Hair, pathologist to the hospital, for the microscopical examination of the growth.

ROYAL DEVON AND EXETER HOSPITAL, EXETER.

TWO CASES OF ACTINOMYCOSIS.

(Under the care of Mr. C. E. BELL and Mr. J. D. HARRIS.)

FOR the notes of the cases we are indebted to Mr. P. H. Stirk, house surgeon.

CASE 1.—The patient, a fisherman, aged 38 years, was admitted under the care of Mr. C. E. Bell to the Royal Devon and Exeter Hospital on Jan. 15th, 1903. Two months before admission the patient was taken suddenly ill with pain in the bowels. He vomited and was unable to pass anything by the bowel for two days; then his bowels acted and he was somewhat relieved. The medical man who attended told him that he had appendicitis. He was fed upon nothing but milk and kept in bed for thirteen days. Since then he had had an abdominal swelling, which he thought varied somewhat in size from time to time, but was at the time of admission larger than it had ever been. He had no pain or trouble with his bowels after the first attack.

On admission, the patient was found to be emaciated and very weak with a temperature of 101° F. There was a large red, slightly œdematous swelling in the abdominal wall situated below the umbilicus and extending downwards to the pubes and a little to the right of the middle line. It was hard, not tender or painful, and dull to percussion. It not only involved the abdominal wall but seemed to go deep into the peritoneal cavity. On inquiry the patient was of opinion that the abdominal wall had only been involved for the last month. There was no evidence of disease in the respiratory, cardiac, or genito-urinary systems.

The progress of the case was as follows. Four days after admission the skin was more red than on admission and at one point immediately below the umbilicus there was a soft, fluctuating patch. This was opened and about an ounce of pus was evacuated which contained the characteristic granules in large numbers. These when stained showed large quantities of the streptothrix but no clubs. 15 grains daily of iodide of potassium were given and later increased to half a drachm daily. He seemed to improve locally and in general health. The swelling was opened in several places and similar material was obtained. Inoculation of nutrient gelatin resulted in a growth of staphylococci, streptococci, and a bacillus resembling the bacillus coli communis; there was no growth of actinomycosis. Five months after admission the patient had so much improved that he insisted on being made an out-patient. He was then able to get about, the swelling had much diminished, his temperature had been quite normal for a month, and he had gained flesh although he was still very emaciated. The patient lived many miles from the hospital and in consequence attended very irregularly. After two months he developed a cough with expectoration and was unable to go to the hospital. He was then attended locally and judging from information kindly given by his medical attendant there is little doubt that he died from extension of the disease to his lung ten months after the commencement of the illness, but no post-mortem examination was made.

CASE 2.—The patient, a female domestic servant, aged 28 years, was admitted under the care of Mr. J. D. Harris to the Royal Devon and Exeter Hospital in July, 1902. She had always had good health with the exception of one illness ten years before admission for which she was treated at this hospital; reference to the old notes of her case showed that she was an in-patient suffering from strumous glands in her neck and also consolidation and râles at the right apex. The course of her temperature at that time was also suggestive of tuberculous trouble. The family history was good. With regard to the history of her present illness, four months before admission the patient said she suffered very much from toothache in the left lower jaw and she had several decayed teeth removed. At that time there was no swelling but after the extraction an abscess formed and was opened, and since then the swelling had gradually formed.

On admission the patient was found to be anæmic but well nourished. There was a swelling on the left side of the lower maxilla extending from the angle of the jaw to the middle line; it extended upwards over the lower part of the face and downwards over the upper part of the neck; as a whole, it was deep red in colour, with patches of dark purple which were soft, fluctuating, and tender. Apart from these patches the tumour was very hard and painless on manipulation; the edges were abrupt and well defined; the teeth could only be separated about a quarter of an inch so that it was impossible to examine the mouth. There was no evidence of disease in the respiratory or digestive systems. Several of the fluctuating spots were opened and a small quantity of thick purulent material was obtained. This contained granules which, when stained by Gram's method showed abundance of the streptothrix actinomyces but no clubs.

The progress of the case was as follows. The patient was put on 15 grains of iodide of potassium per diem, subsequently increased to two drachms, and the tumour soon became smaller. Several fluctuating spots formed and were dealt with by incision. The iodide of potassium was taken until June, 1903, when she was discharged cured, the tumour having disappeared and its site being occupied by healthy scar tissue. (Mr. Harris heard from the patient during the month of February, 1904, that she was quite well and had taken a situation in London.)

Remarks by Mr. STIRK.—As recently as 1891 Professor E. M. Crookshank[1] is reported to have said that actinomycosis was undoubtedly found in man but was not of sufficient frequency to make it an important disease. Since then so many cases have been reported, both in this country and particularly abroad, that one is forced to conclude either that the disease formerly was generally unrecognised or that it has become much more frequent. Probably the apparent increase is due to improved diagnostic methods. Case 1 is of special interest as showing how this form of the disease may resemble appendicitis; similar cases have been recorded by Ransom,[2] Kern,[3] Fairweather,[4] and others. In a thesis published in 1897 Honglais collected 120 cases of appendicular actinomycosis. In this case the chief points which made one suspect that it was not an ordinary case of appendix abscess were the absence of pain and tenderness, the length of the history, and the absence of such grave constitutional symptoms as one is accustomed to see in appendicitis. Dr. Grill[5] of Tübingen, in an analysis of 107 cases collected from the literature, finds that abdominal actinomycosis is most frequent next to that of the head and neck; the ileo-cæcal valve is the part most often affected, and the disease not infrequently resembles appendicitis. The prognosis is best in those cases in which the abdominal wall is involved early and the viscera are not extensively diseased. In 77 cases of abdominal actinomycosis 46 died, 22 were cured, and ten improved. Vander Veer and Elting[6] say that 50 per cent. of abdominal cases occur in the cæcum or appendix. Heinzelmann[7] reports 11 cases with three cures. Of 12 abdominal cases I have been able to collect from recent literature nine died, one was cured, and two are reported as in good general health but still under treatment.

Case 2 is of interest as showing the possibility of the fungus having obtained admission through the carious teeth or the wounds resulting from their extraction and also from the apparently beneficial results from the administration of iodide of potassium. A report of experiments made at Chicago in the treatment of cattle suffering from actinomycosis gives 63 per cent. of cures effected by the drug but in human actinomycosis it does not appear to be so successful. The manner in which it acts is not certain. That it has no direct action on the fungus itself is probable because a solution of iodide of potassium added to nutrient media is said to have no influence on the growth of the fungus and how much its action is modified by the presence of secondary infection is also uncertain. Reports of human actinomycosis treated by iodide of potassium differ very much in results; in some it has had most marked curative effect and in other cases it is reported to have had practically no influence. It would appear to be of most value in cases of probably pure actinomycosis unassociated with secondary infections. The treatment most likely to be successful is early operation where possible, together with the iodide given internally in very large doses.

Medical Societies.

OBSTETRICAL SOCIETY OF LONDON.

Exhibition of Specimens.—Hydatid Disease in the Abdomen and Pelvis.

A MEETING of this society was held on June 1st, Dr. EDWARD MALINS, the President, being in the chair.

Dr. C. H. J. LOCKYER showed a specimen of Primary Carcinoma of Both Ovaries removed by operation from a woman, 47 years of age. Both Fallopian tubes, though apparently normal, under the microscope were found to be infiltrated with cancer elements. On this account Dr. Lockyer suggested that in similar cases the tubes, even though apparently healthy, should be removed along with the ovaries.—Dr. MARY THORNE described a case in which the left ovary was removed by operation in a patient, aged 46 years, the other ovary at the time of the operation being apparently healthy. The patient died four months later, when a deposit was found in the right ovary; the ileum had been implicated by recurrence at the original site of operation and secondary nodules had formed in the liver.

Dr. HERBERT R. SPENCER showed a specimen of Cancer of the Body of the Uterus occurring in a woman, aged 36 years.

Dr. T. W. EDEN recorded a case of Primary Hydatid Disease (Echinococcus) of the Fallopian Tube. The patient was a woman, 40 years of age, who had been married for 13 years, had never been pregnant, and presented herself at the Chelsea Hospital for Women in July, 1903, complaining of pain in the back and left side. On examination a small pelvic tumour was found in the pouch of Douglas which from its position and characters was thought to be a dermoid cyst of the right ovary. Operation was performed on Sept. 10th, when the tumour was found to be the distended and densely adherent right Fallopian tube filled with detached hydatid vesicles. The ovary was quite separate and unaffected except by adhesions. The tube and ovary of the left side were adherent but otherwise unaffected. There was no trace of hydatid disease elsewhere. The patient made a good recovery. Dr. Eden believed that only one other case of primary hydatid disease of the Fallopian tube was on record—namely, the one described by Doléris in 1896. With regard to the ovary, he believed that only one case of primary hydatid disease of that organ had been recorded—namely, the one described by Péan in 1895. Pelvic hydatids usually began in the peritoneum or connective tissue.

Dr. C. J. CULLINGWORTH and Mr. H. H. CLUTTON contributed a paper giving an account of Hydatids in various parts of the Abdomen of a patient who had been under their joint care from time to time during the last eight years. She first came under observation in the summer of 1896, when 24 years of age, with a rounded, fixed, fluctuating swelling in the suprapubic region which was thought to be a cystic tumour of the ovary or of the broad ligament. At the operation there were found hydatid cysts of both ovaries and of the right broad ligament and, in addition to those, hydatid cysts of the omentum, mesentery, and anterior abdominal wall. A larger cyst was also observed in the right loin and a second one beneath the lower end of the sternum. The cysts connected with the ovaries and the broad ligament and as many as possible of the omental cysts were removed. The operation lasted two and a half hours and the patient's condition towards the end became extremely alarming. Three months later, in October, 1896, Mr. Clutton made an incision above the umbilicus with a view to deal with the remaining cysts. He found three large and several smaller cysts attached to the liver. All except two were removed entire; the ectocystic walls of the two largest were reduced in size and attached to the abdominal incision. The shock of the operation was extreme. Another large cyst felt towards the spleen had to be left for a subsequent operation. In November of the same year a large cyst in the left iliac fossa was evacuated and a week later a suppurating hydatid cyst discharged its contents per rectum. Between this time

perated upon on eight

the longest one being

ed in evacuation of a large hydatid cyst in the pelvis by means of an incision through the vaginal roof. The other severe operations were performed through the anterior abdominal wall, several of them without opening the peritoneal cavity. The various operations were briefly described. Dr. Cullingworth and Mr. Clutton could not, of course, say that the patient would have no further development of hydatid cysts, but as the case had now extended over a period of eight years they thought the present a good opportunity to place on

up to the present time.—

he case narrated by Dr.

to admire most—the persistence of the surgeons or the fortitude and endurance of the patient. The success ultimately attained justified the repetition of the operation and the wisdom in dealing with the recurrences.—Mr. CLUTTON said that the patient owed her present satisfactory condition to the fact that, contrary to the usual experience, the development of hydatid cysts had in her case been hitherto limited to the abdomen. Had the disease affected the thorax or the brain, as so often happened, the result might have been very different.—Mr. J. BLAND SUTTON suggested that Dr. Cullingworth's specimen should be re examined to determine whether the colony really arose in the ovary or in the connective tissue of the broad ligament and as it increased in size flattened the ovary over its periphery. In the distribution of echinococcus colonies among the abdominal viscera the parasite in the great majority of instances really selected the subserous tissue. This was true of the kidney where they flourished in the connective tissue of the renal sinus, the bowel, the broad ligament, the omentum, and the rectum. The immunity of the ovary depended on the fact that it lacked a loose serous investment and this was also true of the testis which seemed equally immune with the ovary to these parasites. The loose connective tissue of the mesosalpinx and the adjacent portion of the broad ligament formed admirable environments for the maturation of the embryo of tænia echinococcus but was not quite so accessible as the loose connective tissue of the mesocolon, the mesorectum, or the omentum. The multiplicity of lesions depended on the number of ova swallowed; the extraordinary number of cysts in some patients would suggest the probability that occasionally an entire proglottis had been ingested. It seemed also certain that the brood-cysts might be sown into the connective tissue of the wounds made for their removal, a view supported by the frequency with which echinococcus cysts grew in the cicatrices of operation wounds made for the removal of primary colonies. Of this Mr. Bland-Sutton had observed several cases in his own practice.

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN.

Delayed Chloroform Poisoning.

A SPECIAL meeting of this society was held on May 20th at Chandos-street, W., Mr. W. WATSON CHEYNE being in the chair.

Mr. HAROLD J. STILES (Edinburgh) and Dr. STUART MCDONALD (Edinburgh) contributed a paper on Delayed Chloroform Poisoning. Mr. Stiles, in his introductory remarks on behalf of himself and Dr. McDonald, said that although the occurrence of delayed chloroform poisoning had long been recognised in Germany Dr. Leonard G Guthrie, a fellow member of the society, was the first to direct attention to the subject in this country. His first paper, published in THE LANCET,[1] was entitled "Some Fatal

---

[1] THE LANCET, Jan. 27th (p. 193) and Feb. 3rd (p. 257), 1894.

After-Effects of Chloroform on Children." In a second paper published in the same journal[2] Dr. Guthrie brought forward further observations in support of his contention that the fatty changes met with in delayed chloroform poisoning were not due to the action of chloroform alone; he maintained that the liver was in an advanced state of fattiness previously to the administration of the chloroform and that the latter, by diminishing oxidation, already deficient, determined the state of functional inadequacy which set up an auto-intoxication due to the accumulation of ptomaines or toxins. Mr. Stiles then described the clinical history and pathological changes in two children who died, the one three days after operation for the radical cure of hernia and the other 26 hours after an osteotomy for knock-knee. It was shown that death could not have resulted from carbolic acid poisoning, from fat embolism, or from sepsis. In the osteotomy case the fat emboli in the lungs were only present in the smallest vessels and were so scarce that death could not be attributed to them. It was interesting to note that some of the sub-lobular and hepatic veins contained a considerable amount of oil, for the most part in free droplets, but occasionally in the interior of what were evidently disintegrated liver cells. No fat was demonstrated in branches of the hepatic artery, nor could any be discovered on the aortic side of the circulation. It was evident, therefore, that the fat in the lungs was derived from that which had gained access into the hepatic veins from the disintegrated liver cells. The possibility of sepsis was carefully considered. Lantern slides and microscopical specimens (obtained from a child who died from a gangrenous inflammation of the œsophagus following operation for perityphlitis) were demonstrated to show how closely the degenerative changes in the liver, kidneys, and heart resembled those which are said to be characteristic of delayed chloroform poisoning. In neither condition were there any inflammatory changes in the glomeruli. The fact was emphasised that the same degenerative changes were sometimes present in patients who had died after operations for septic conditions, especially of abdominal origin, as were found in patients who had died from delayed chloroform poisoning uncomplicated with sepsis. The hope was expressed that pathologists would inquire more closely into the nature and causation of the degenerative changes to be found in the above-mentioned organs in surgical cases. Unfortunately the pathology and symptoms of delayed chloroform poisoning had up to recently been either overlooked or wrongly interpreted, so that the mortality could not be estimated until the condition had become generally recognised by surgeons and pathologists. With one exception the cases recorded in this country had all occurred in children while under treatment either in the Paddington-green Children's Hospital or in the Edinburgh Royal Hospital for Sick Children, these being two hospitals where special attention had been directed to the condition. In Germany, on the other hand, almost all the reported cases had been in adults and the greater proportion of these had occurred after a somewhat severe operation for infective abdominal conditions such as suppurative salpingitis, appendicitis, &c. The element of sepsis with which these cases were complicated rendered it difficult, in the present state of their knowledge, to say how far they helped to solve the problem of delayed chloroform poisoning. If it could be shown that the critical condition (persistent vomiting of a more or less hæmorrhagic type; small, rapid, and often irregular pulse; extreme restlessness, collapse, &c.) in which they occasionally found patients 48 hours or so after operation was in any way brought about by degenerative changes set up by the chloroform the question of substituting ether would have to be considered seriously even in the case of children. Unfortunately, however, the mortality in children from the effects of ether on the respiratory tract would probably be as great as, if not greater than, that due to the after-action of chloroform. It was not thought that Dr. Guthrie had brought forward sufficient evidence to show that the fatty change here described was the essential predisposing factor and that the chloroform merely acted as the "last straw." It was thought much more probable that the fatty change was entirely due to the chloroform acting on a previously healthy liver; indeed, experimental evidence seemed to give strong support to this possibility. Moreover, while the changes in the liver were so striking it must not be forgotten that other organs gave evidence of a general toxic poisoning, and it seemed hardly justifiable, therefore, to attribute the fatal result to hepatic insufficiency. Fatal cases of delayed chloroform poisoning were undoubtedly very rare and it would appear, therefore, that idiosyncrasy was the main factor in their causation just as it was in the irreducible minimum of deaths which occurred during chloroform anæsthesia. As regards the treatment of delayed chloroform poisoning Mr. Stiles and Dr. McDonald entirely agreed with Dr. Guthrie in strongly condemning the use of morphine. Rectal and subcutaneous injections of normal saline solution and if necessary intravenous injections must be employed. If the vomiting were copious the stomach should be washed out and an endeavour should be made to get it to retain some calomel or grey powder. Cardiac stimulants must be used but in moderation.

Mr. **WATSON CHEYNE** said that he was still not quite convinced that the chloroform was the only causative factor in these cases and that they must be looked on as after-effects of the administration of that anæsthetic. Although he had had two or three cases at Paddington-green Children's Hospital he thought it was very remarkable that he had never met with similar occurrences either at King's College Hospital or in private practice. The extremely short administration in some of the cases—for example, tenotomy—and the minute dose administered made it very difficult to believe that the chloroform was the cause of the fatal result.

Dr. **LEONARD GUTHRIE** thought that the frequency of these fatalities following operations under chloroform upon children might be greater than was indicated by the number of cases recorded in this country. Ten years previously he had published in THE LANCET a series of ten cases, nine of which had happened at the Children's Hospital, Paddington-green. Since then three more had occurred at the same institution. He doubted whether such experience was unique. Possibly a search in the archives of other children's hospitals might reveal more cases of a similar nature. The case against chloroform was that prolonged and repeated inhalation of that anæsthetic produced in animals profound fatty changes, not only in the liver but in the kidneys and other organs, and that such changes were almost constantly found in children dying in the manner described after operations under chloroform. But on the other hand it was difficult to conceive that such extreme fatty changes could be induced by the small amounts of chloroform absorbed during a period of anæsthesia which in some cases did not exceed a quarter of an hour or 20 minutes. Hence he inclined to the view that a fatty condition of the liver was pre-existent at the time of operation in such cases, that chloroform by its deoxidising powers aggravated and intensified the fatty changes present, and thus rendered the liver incapable of dealing with toxins entering the portal system from the intestines. The result was that such toxins passed into the general circulation and could not be eliminated on account of the specific action of the chloroform on the kidneys. The rôle of the chloroform was therefore that of the "last straw." The existence of such fatty livers might be suspected though it could not be proved by the history of so called "bilious attacks" characterised by vomiting, headache, epigastric pain, diarrhœa, or constipation associated with the odour of acetone in the breath and urine. When such a history was obtained ether should be the anæsthetic used, as experiments on animals showed that ether possessed the power of inducing fatty changes to a far less extent than chloroform.

Dr. **F. W. HEWITT** had never seen any cases at all comparable to these. He supported Dr. Guthrie's request for an inquiry on account of the extreme importance of the subject to the profession. He suggested that one of the children's hospitals should change its customary anæsthetic for one or two years to a mixture of chloroform and ether in order to observe the results.

Mr. **F. F. BURGHARD** remarked that in one of Dr. Guthrie's cases at Paddington-green on which he had operated the notable thing was that death occurred after the *second* time of operating. The case was one of a very large nævus of the chest and arm and the first operation, which had taken place several weeks before, was much the longer and the more severe of the two; nevertheless the child recovered without a symptom of any sort referable to chloroform administration.

Dr. **J. F. W. SILK** confessed that he had been very sceptical with regard to Dr. Guthrie's first paper ten years ago; he was now very astonished to find that it had been discovered in Edinburgh of all places that quite possibly chloroform might produce some ill-effects. He commented on the occurrence of the condition only in older children in spite of the fact that chloroform was given to very large numbers of infants. It was strange also that no relation could be established between the size of the dose administered and the production of the condition.

---

[2] THE LANCET, July 4th, 1903, p. 10.

Mr. H. P. NOBLE had administered the anæsthetic in two of Dr. Guthrie's cases. Perhaps these cases were commoner than was usually supposed. He now thought that two deaths which he witnessed at the Hospital for Sick Children, Great Ormond-street, when he was house surgeon there were probably due to this condition.

Mr. W. J. MCCARDIE (Birmingham) had never seen a case, [illegible]

[illegible] ration due to chloroform administration and showing slight albuminuria, vomiting, and collapse before death. Fatty changes were found in the heart, the liver, and the kidneys. That author laid stress on the kidney lesions, especially on the fact that they were more advanced in the tubules than in the glomeruli, which was a diagnostic feature. He wondered whether such conditions were more apt to occur in lymphatic children, as they stood most adverse influences worse than other children. The moral was always to use ether in children.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Cases.—Anatomy of the Pelvic Fascia.—Anatomy of the Enlarged Prostate.

A MEETING of this society was held on June 1st, Professor JOHN CHIENE, the President, being in the chair.

Dr. NORMAN WALKER showed three men suffering from Lupus complicated with Epithelioma. One of these was aged 32 years and had suffered from lupus since infancy. An epitheliomatous mass appeared on his face about one and a half years ago and it has to be noted that no x-ray treatment had been employed in this case previously to the development of the cancer. Since April, 1904, he had been treated with five-minute exposures to the x rays every second day and the result was excellent. The other two patients had been treated with the x rays for lupus before the appearance of the epithelioma. Dr. Walker also showed a case of Diffuse Psoriasis treated by the x rays. He had been sceptical as to this mode of treating the disease but with no other treatment than 14 exposures the disease had practically disappeared.

Mr. GEORGE CHIENE exhibited the following cases. 1. A man after operation for Rupture of the Middle Meningeal Artery and Laceration of the Temporo sphenoidal Lobe. The patient received a blow and as a result fell. It could not be determined which of these caused the injury. He was kept in prison for two days and while there wrote a letter. His gait was, however, noticed to be peculiar and he was admitted to the medical wards of the Royal Infirmary. Five [illegible]

[illegible] substance was seen to be lacerated. The bleeding was from a point low down. It was evidently a case of intradural middle meningeal hæmorrhage. A solution of adrenalin chloride was applied and the artery was ligatured by means of a cleft palate needle. Gradual recovery took place, though even now there were marked signs of irritability and the man lost his temper on very slight provocation. His speech was now good except when he was excited. 2. An infant on whom Laparotomy for Acute Intussusception was performed when 40 days old. Reduction was difficult but was facilitated by the application of swabs of hot sterilised wool. 3. A child after Laparotomy for a second attack of Acute Intussusception. The first operation was performed when the child was four and a half months old. After recovery the infant suffered from attacks of measles and pertussis and 18 months after the first operation suffered from a second intussusception which also had to be treated by laparotomy. Even at present the child suffered from constipation and difficulty in regulation of the bowels. Both children were now strong and healthy.

Dr. W. ALLAN JAMIESON showed a case of Keloid treated by the X Rays. The patient was a female aged 26 years. In October, 1893, she suffered pain in the region of the left breast with tenderness on pressure. This was treated for several days by rubbing in acetic acid for an hour on each occasion. This caused abrasion of the skin followed by extensive suppuration. On healing keloid appeared. On examination in March, 1904, many spots and patches of keloid were present, the area involved measuring three and a half inches in vertical height by two and a half inches across. Numerous minute outlying dots were also present. The surface was bright pink and the ridges were elevated about one third of an inch above the skin level. She had been treated by 44 exposures to the x rays of five minutes' duration each, with the result that all the smaller points had disappeared and the larger ones had almost faded. As she was anæmic ten grains of iron alginate had been administered most of the time. She was pregnant.

Dr. JOHN STEVENS showed a young man who, as a result of infantile paralysis, suffered from extensive and almost Complete Atrophy of the Muscles of the Shoulders, Arms, Forearms, and Hands, especially on the left side.

Dr. EDWIN BRAMWELL demonstrated a case of Klumpke's Paralysis in a man. This was a lesion of the eighth cervical and first dorsal nerve roots. The man had fallen from a height of 20 feet, striking against the right side of the head and right shoulder. At first there was complete loss of power in the arm, though this had improved very considerably. Most of the muscles of the arm and forearm were normal, but the flexors of the hand on the wrist and also the interossei were atrophied, as well as the muscles of the thenar and hypothenar eminences. The power of opposing the thumb was almost absent. The little finger could not be abducted. All the small muscles of the right hand, the two long flexors, as well as the flexor carpi ulnaris were weak and consequently the grasping power of the hand was feeble. There was also anæsthesia of the skin with a very definite distribution as a linear band running down the inner side of the upper arm and forearm and splitting at the ring finger.

Dr. GEORGE GIBSON exhibited a case of so-called Hypertrophic Pulmonary Osteo-arthropathy in a patient (male) suffering from slight emphysema. Over the last two phalanges of each finger the skin was sodden-looking, always moist, and devoid of hair. These areas corresponded to the nerve distribution of the ventral divisions of the nerves of the back of the hand.

Dr. DAVID WATERSTON read a communication entitled "Some Points in the Anatomy of the Pelvic Fascia in the Male in Relation to the Surgery of that Region." He said that there was a difference of opinion among surgeons regarding the best method of removing the prostate gland and this had led to a fresh examination of the anatomy of the perineal region both by section and by dissection. The improved methods now available gave clearer results than were formerly attainable and might be of service in demonstrating the advantages and difficulties of each method. Taking up first the best means of access to the organ from the perineum Dr. Waterston exhibited lantern pictures from photographs of formalin preparations of the anatomy of the perineum. The specimens showed that the superficial layer of the triangular ligament was not intimately related to the urethra but was *attached round the margin* of the bulb and that Cowper's glands lay in intimate relation to the deep aspect of the bulb and were not separated from it by a strong membrane. This explained the course of extravasated urine into the perineum in cases where the membranous urethra was torn. Taking next the musculature of the perineum it was pointed out that the muscle tissue was arranged in a very complex manner. This subject had been investigated and thoroughly discussed in the early part of the last century, but as the arrangement was very complex and difficult to demonstrate the full description was omitted from most anatomical text-books. Such structures as Wilson's muscle and the compressor of Cowper's glands were not now described. But recent advances in operative work on this region had led to descriptions by several writers, mostly continental, of structures which were found to be of surgical importance, such as the muscle passing from the anal canal to the membranous urethra. This muscle was shown and attention was directed to the thick anterior part of the levator ani muscle and to the strong character of the deep layer of the triangular ligament which was pierced by the urethra and also supported the prostate. The sheath which the prostate possessed, derived from the visceral

After-Effects of Chloroform on Children." In a second paper published in the same journal[2] Dr. Guthrie brought forward further observations in support of his contention that the fatty changes met with in delayed chloroform poisoning were not due to the action of chloroform alone; he maintained that the liver was in an advanced state of fattiness previously to the administration of the chloroform and that the latter, by diminishing oxidation, already deficient, determined the state of functional inadequacy which set up an auto-intoxication due to the accumulation of ptomaines or toxins. Mr. Stiles then described the clinical history and pathological changes in two children who died, the one three days after operation for the radical cure of hernia and the other 26 hours after an osteotomy for knock-knee. It was shown that death could not have resulted from carbolic acid poisoning, from fat embolism, or from sepsis. In the osteotomy case the fat emboli in the lungs were only present in the smallest vessels and were so scarce that death could not be attributed to them. It was interesting to note that some of the sub-lobular and hepatic veins contained a considerable amount of oil, for the most part in free droplets, but occasionally in the interior of what were evidently disintegrated liver cells. No fat was demonstrated in branches of the hepatic artery, nor could any be discovered on the aortic side of the circulation. It was evident, therefore, that the fat in the lungs was derived from that which had gained access into the hepatic veins from the disintegrated liver cells. The possibility of sepsis was carefully considered. Lantern slides and microscopical specimens (obtained from a child who died from a gangrenous inflammation of the œsophagus following operation for perityphlitis) were demonstrated to show how closely the degenerative changes in the liver, kidneys, and heart resembled those which are said to be characteristic of delayed chloroform poisoning. In neither condition were there any inflammatory changes in the glomeruli. The fact was emphasised that the same degenerative changes were sometimes present in patients who had died after operations for septic conditions, especially of abdominal origin, as were found in patients who had died from delayed chloroform poisoning uncomplicated with sepsis. The hope was expressed that pathologists would inquire more closely into the nature and causation of the degenerative changes to be found in the above-mentioned organs in surgical cases. Unfortunately the pathology and symptoms of delayed chloroform poisoning had up to recently been either overlooked or wrongly interpreted, so that the mortality could not be estimated until the condition had become generally recognised by surgeons and pathologists. With one exception the cases recorded in this country had all occurred in children while under treatment either in the Paddington-green Children's Hospital or in the Edinburgh Royal Hospital for Sick Children, these being two hospitals where special attention had been directed to the condition. In Germany, on the other hand, almost all the reported cases had been in adults and the greater proportion of these had occurred after a somewhat severe operation for infective abdominal conditions such as suppurative salpingitis, appendicitis, &c. The element of sepsis with which these cases were complicated rendered it difficult, in the present state of their knowledge, to say how far they helped to solve the problem of delayed chloroform poisoning. If it could be shown that the critical condition (persistent vomiting of a more or less hæmorrhagic type; small, rapid, and often irregular pulse; extreme restlessness, collapse, &c.) in which they occasionally found patients 48 hours or so after operation was in any way brought about by degenerative changes set up by the chloroform the question of substituting ether would have to be considered seriously even in the case of children. Unfortunately, however, the mortality in children from the effects of ether on the respiratory tract would probably be as great as, if not greater than, that due to the after-action of chloroform. It was not thought that Dr. Guthrie had brought forward sufficient evidence to show that the fatty change here described was the essential predisposing factor and that the chloroform merely acted as the "last straw." It was thought much more probable that the fatty change was entirely due to the chloroform acting on a previously healthy liver; indeed, experimental evidence seemed to give strong support to this possibility. Moreover, while the changes in the liver were so striking it must not be forgotten that other organs gave evidence of a general toxic poisoning, and it seemed hardly justifiable, therefore, to attribute the fatal result to hepatic insufficiency. Fatal cases of delayed chloroform poisoning were undoubtedly very rare and it would appear, therefore, that idiosyncrasy was the main factor in their causation just as it was in the irreducible minimum of deaths which occurred during chloroform anæsthesia. As regards the treatment of delayed chloroform poisoning Mr. Stiles and Dr. McDonald entirely agreed with Dr. Guthrie in strongly condemning the use of morphine. Rectal and subcutaneous injections of normal saline solution and if necessary intravenous injections must be employed. If the vomiting were copious the stomach should be washed out and an endeavour should be made to get it to retain some calomel or grey powder. Cardiac stimulants must be used but in moderation.

Mr. **WATSON CHEYNE** said that he was still not quite convinced that the chloroform was the only causative factor in these cases and that they must be looked on as after effects of the administration of that anæsthetic. Although he had had two or three cases at Paddington-green Children's Hospital he thought it was very remarkable that he had never met with similar occurrences either at King's College Hospital or in private practice. The extremely short administration in some of the cases—for example, tenotomy—and the minute dose administered made it very difficult to believe that the chloroform was the cause of the fatal result.

Dr. **LEONARD GUTHRIE** thought that the frequency of these fatalities following operations under chloroform upon children might be greater than was indicated by the number of cases recorded in this country. Ten years previously he had published in THE LANCET a series of ten cases, nine of which had happened at the Children's Hospital, Paddington-green. Since then three more had occurred at the same institution. He doubted whether such experience was unique. Possibly a search in the archives of other children's hospitals might reveal more cases of a similar nature. The case against chloroform was that prolonged and repeated inhalation of that anæsthetic produced in animals profound fatty changes, not only in the liver but in the kidneys and other organs, and that such changes were almost constantly found in children dying in the manner described after operations under chloroform. But on the other hand it was difficult to conceive that such extreme fatty changes could be induced by the small amounts of chloroform absorbed during a period of anæsthesia which in some cases did not exceed a quarter of a hour or 20 minutes. Hence he inclined to the view that a fatty condition of the liver was pre-existent at the time o operation in such cases, that chloroform by its deoxidising powers aggravated and intensified the fatty changes present, and thus rendered the liver incapable of dealing with toxins entering the portal system from the intestines. The result was that such toxins passed into the general circula tion and could not be eliminated on account of the specifi action of the chloroform on the kidneys. The rôle of the chloroform was therefore that of the "last straw." The existence of such fatty livers might be suspected though i could not be proved by the history of so called "biliou attacks" characterised by vomiting, headache, epigastri pain, diarrhœa, or constipation associated with the odour o acetone in the breath and urine. When such a history wa obtained ether should be the anæsthetic used, as experi ments on animals showed that ether possessed the power o inducing fatty changes to a far less extent than chloroform.

Dr. F. W. **HEWITT** had never seen any cases at all com parable to these. He supported Dr. Guthrie's request for a inquiry on account of the extreme importance of the subjec to the profession. He suggested that one of the children' hospitals should change its customary anæsthetic for one o two years to a mixture of chloroform and ether in order t observe the results.

Mr. F. F. **BURGHARD** remarked that in one of Dr. Guthrie' cases at Paddington-green on which he had operated th notable thing was that death occurred after the *second* tim of operating. The case was one of a very large nævus of th chest and arm and the first operation, which had taken plac several weeks before, was much the longer and the mo severe of the two; nevertheless the child recovered without symptom of any sort referable to chloroform administration.

Dr. J. F. W. **SILK** confessed that he had been very sceptic with regard to Dr. Guthrie's first paper ten years ago; he w now very astonished to find that it had been discovered i Edinburgh of all places that quite possibly chloroform mig produce some ill-effects. He commented on the occurren draughtsman. Sir William Gowers describes the inhibition of function with the visual discharge of migraine and endeavours to trace the connexion with central changes. The whole account of migrainous spectra teems with interest but for adequate appreciation the lecture must be consulted rather than summarised here; it may, however, be regretted that the figures are not coloured.

---

[2] THE LANCET, July 4th, 1903, p. 10.

In dealing with subjective sensations of sound Sir William Gowers lays stress upon the persistence which soon convinces the sufferer that they cannot be due to an external cause and he notes that patients complain of noises *in* the ears and noises *in* the head. While much interest attaches to the classification of the varieties of these auditory forms of subjective sensation and to the discussion of their relation to vertigo, Sir William Gowers, though hopeful about the future, is not very cheering as to the present means of treating this troublesome condition. The chief lesson which he teaches is the futility of tying the internal carotid.

Other lectures included in this volume are upon Abiotrophy, Myopathy, Metallic Poisoning, Syphilitic Disease of the Nervous System, Syringal Hæmorrhage into the Spinal Cord, and Myasthenia and Ophthalmoplegia. The lecture on abiotrophy was published in our columns about two years ago[1] and it will be remembered for the ability with which Sir William Gowers suggested this new term and explained the scope of its meaning. He shows that the conception of abiotrophy is of great service in connexion with numerous forms of cutaneous, muscular, and nervous changes and he clearly indicates its relationship to the interstitial overgrowth which occurs with so many primary changes in the nervous system. His conclusion is that the new conceptions in this article will enable us to think more clearly about processes which we do not understand. This cryptic remark implies the adoption of the conceptions as working hypotheses or as algebraic symbols which may favour the attainment of ultimate truth through intermediate patches of obscurity. The two lectures on Inevitable Failure and the Use of Drugs, which seem rather disconnected from the general plan, yet have peculiar value for the thoughtful treatment bestowed upon them. Looking back gratefully to his apprenticeship to a general practitioner the author says that he learnt thus early that treatment by drugs does in a large number of cases not only a definite but a great amount of good, and while contrasting empirical and rational treatment his respect for modern experiment is exceeded by his reverence for experience which he defines as the result of innumerable experiments.

Enough has been said to show the wide scope of these lectures and the interest which they possess for all professional men. They are written in striking terms, with apt illustrations and numerous studied epigrams. The author proclaims that so far from liking new words he dislikes them and yet it would be possible to cull from this volume a fairly large number with which he has enriched medical diction, and most of them, in American parlance, have "come to stay" and have already been of service to others who desire to express a conception for which no name previously existed.

The Extra Pharmacopœia of Martindale and Westcott. Revised by W. HARRISON MARTINDALE, Ph.D., F.C.S., and W. WYNN WESTCOTT, M.B. Lond., D.P.H., His Majesty's Coroner for North-East London. Eleventh edition. London: H. K. Lewis. 1904. Pp. xxiv.–809. 24mo, roan limp. Price 9*s*. 6*d*. net.

IT is a little more than 20 years since the first appearance of the Extra Pharmacopœia and the popularity and utility of the book can be gathered from the rapidity with which new editions have been issued. There can be no doubt that this epitome of recent work has been much valued by those who are unable to keep pace with the advances of pharmacy which are chronicled in the pharmaceutical and medical journals. The appreciation of former editions of this volume is largely due to the frequent references to the original sources from which it has been compiled, but in addition it must be admitted that the general level of excellence of the selection of material renders an invaluable service to busy practitioners. In the present edition space has been gained by the deletion of much that was getting a little antiquated. The plan and scope inevitably lead to the temporary inclusion of many drugs of an ephemeral character and the authors are to be commended for the judgment displayed in the deletions necessary to make room for more recent and perhaps more valuable additions.

In spite of every care it has been found necessary to add more than 100 pages and, yet, by the employment of thinner paper, the size and weight are appreciably less than in the last edition. The scope of the work has been extended by the addition of several new sections and while these are useful in some instances they seem to be a little out of place in a work of this character; the section on surgical dressings and apparatus, which occupies 12 pages, seems to be little more than extracts from an unpriced catalogue. Mild surprise will also be felt at the inclusion of 14 pages relating to mineral waters. The information is trustworthy and valuable, it is interesting to know the chemical constituents, the uses and the season at which the health resorts may be visited, but the whole section is scarcely suggested by the title of the book and might well have been omitted. In like fashion the space devoted to radium might have been reduced; an attempt is made to tell too much relating to the extraction and to the chemical properties of radium. Roentgen rays, high-frequency current, the Finsen lamp, and radiant heat are also briefly dealt with but in all of these we feel that the information is incomplete as well as redundant. When dealing with subjects more purely related to pharmaceutical work the authors are far more happy. There is much that is admirable in the critical remarks on the weights and measures of the British Pharmacopœia and a step in advance has been made in the insertion of doses on the metric system. The lengthy list of chemicals, drugs, galenical preparations, and modes of treatment which have claimed recent attention sufficiently indicates the charitable catholicity which aims at the inclusion of all things. In fact, the present edition errs, perhaps, in the attempt to supply answers to all possible questions relating to new drugs without sufficiently holding the balance between good and bad, valuable and worthless. A similar excursion into outlying provinces occurs in the preface where the authors state that, "the recent deaths by carbon monoxide, carbon dioxide, and illuminating gas poisoning have made it necessary to mention the methods of detection of these noxious gases." Why is it necessary to do this? Are there not other books in which such information would be more appropriate? It is in no spirit of carping criticism that we object to the introduction of extraneous matter; it is because the book in its earlier form has proved so useful to professional men that we regret to see it altered in scope and character, to find its excellencies in danger of being obscured or hidden by the introduction of redundancies for which there appears to be no justification. An immense amount of labour has obviously been expended in the abstraction of the literature relating to methods of treatment and to recent pharmaceutical research work.

The general character of the Extra Pharmacopœia is so well established that medical men will welcome a new edition which has been brought up to date. They will find therein all that they require relating to advances in pharmacy. If they realise also that they are supplied with more than they anticipated or desired in other directions it is to be hoped that they will not feel disposed to complain. We think the authors are mistaken in the liberality with which they include antitoxins, analytical memoranda, and much other information, but can heartily commend the sections dealing with drugs and galenicals for their fulness and accuracy.

---

[1] THE LANCET, April 12th, 1902, p. 1003.

A Manual and Dictionary of the Flowering Plants and Ferns. By J. C. WILLIS, M.A., Director of the Royal Botanic Gardens, Ceylon, some time Frank Smart Student, Gonville and Caius College, Cambridge, and Senior Assistant in Botany in the University of Glasgow. Second edition. Cambridge: at the University Press. 1904. Pp. xii.-670. Price 10*s.* 6*d.*

THE object of this work is "to supply within a reasonable compass a summary of useful and scientific information about the plants met with in a botanical garden or museum, or in the field." As the author very truly remarks further in his preface, "the student, when placed before the bewildering variety of forms in such a collection as that at Kew, does not know where to begin or what to do. ...... The available works of general reference are mostly very bulky and often out of date, and as a rule refer only to systematic or economic botany, and say nothing about morphology or natural history." Therefore the author has endeavoured to bring together in his book in a systematic and convenient manner as much information as is required by any but specialists upon all plants usually met with, discussing only those points—morphology, classification, natural history, economic botany, &c.—which do not require the use of a microscope.

The work is made up of three parts, the first of which deals with general considerations regarding the outlines of morphology, natural history, classification, and other kindred branches of botanical science; the second portion is essentially a dictionary fully describing the families and more briefly the important genera of the Pteridophyta and Phanerogamæ, while Part 3 consists of a glossarial index of economic products, technical terms, and so on. The first edition, published seven years ago, was issued in two volumes; the present edition is in one volume and there are further alterations which may be briefly referred to. In order that the work may not exceed a reasonable size Part 1 has been abbreviated by the omission of matters of controversy and by the use of smaller type for descriptive paragraphs and other articles. There have, however, been added valuable articles on practical subjects of interest to field botanists; for instance, the collection and preservation of material. Part 2, which has been revised and rewritten where necessary, is, of course, the most important portion of the book. It is singularly complete and we may safely express the opinion that no important genus about which information may be required by those for whom the work is intended has been omitted. And further, the information given is both sufficient and up-to-date with very few exceptions.

As regards omissions we may perhaps be allowed to draw attention to the following. The presence of spine-bearing roots is a well-known but uncommon feature; there is, however, no reference to their occurrence in *Dioscorea prehensilis*, which plant affords us an excellent example of such a morphological modification. Another instance may be found on p. 300. In the article on Chalazogamæ there is an abstract of Treub's classical work on *Casuarina*, in which the main features of the structure of the embryo-sac and fertilisation are given. The more recent work of Frye on the same subject is not, however, mentioned, which is to be regretted inasmuch as the observations of the latter investigator differ in some important points from those of the former, although the main fact is corroborated.

In conclusion, it may be stated that the work forms a most valuable reference book for all those interested in plants and that no serious student can afford to be without it. These opinions are based not on a hurried perusal but on the experience gained by its use during a number of years; indeed, almost since its first appearance.

The General Pathology of Inflammation, Infection, and Fever. By E. W. AINLEY WALKER, M.A., M.D. Oxon. London: H. K. Lewis. 1904. Crown 8vo. Pp. xii.+260. Price 4*s.* 6*d.*

THIS modest little brochure on the General Pathology of Inflammation, Infection, and Fever is a re-issue of a course of lectures delivered in 1902 and originally published in the *Clinical Journal.* The subject constituted, as the author informs us in his preface, "the first series of Gordon lectures delivered at Guy's Hospital, under the deed of endowment of the Research Lectureship and Laboratory established at that hospital by the munificence of Robert Gordon, Esq., of Brockham-park, for the advancement of the science of medicine and the encouragement of that spirit of investigation and inquiry for which Guy's Hospital is by tradition and history alike most justly famous."

Much has been published in the past on the subjects dealt with in Dr. Walker's lectures and of that a large proportion is controversial in character. A trustworthy and impartial synopsis of our knowledge of these subjects is therefore welcome at the present juncture when questions of infection and immunity are attracting so many workers in the field of experimental research. The present volume certainly fulfils this function, for although in one sense it is a compilation it is a compilation made in a masterly manner. In compact and handy form the original and classical experiments are reviewed and the various theories deduced therefrom are enunciated, discussed in the light of modern research, and finally weighed, the entire mass of accumulated facts being presented in an orderly and logical sequence. The first four lectures are devoted to a systematic study of inflammation, commencing with the conception of this process handed down from the time of Galen. The various modifications and additions down to the most recent definitions propounded by Adami are detailed, and of the many definitions put forward we note the author favours, not unnaturally, that associated with the name of his preceptor Burdon Sanderson, to whom the volume is dedicated. A summary of the phenomena of inflammation which we are quite willing to admit might well replace any or all of the existing definitions rounds off the book. The causes, processes, and progress, and the effects of inflammation are well treated, and incidentally we wish to express our entire agreement with the author in his deprecation of the looseness of language and of thought which ascribes a purposive character to processes occurring in living protoplasm.

Infection and immunity occupy six chapters, undoubtedly the most valuable in the book. After giving the necessary elementary details and definitions the author briefly reviews the rise and progress of our knowledge of microbial infections, then passes on to the discussion of the modes of bacterial action, and after touching on the question of susceptibility proceeds to the study of immunity proper. The views of Metchnikoff, Grohmann, Bouchard, and Ehrlich are in turn presented to the reader and discussed in all their bearings, and in this connexion we do not recollect having previously read a more intelligible and lucid account of Ehrlich's "side-chain" theory of immunity in the English language than that set out by Dr. Walker. The author's own researches on the various phases of immunity entitle him to deal with this subject in an authoritative manner and we confess to some disappointment in finding so little reference to his own work in these lectures, a criticism to which not many authors lay themselves open.

The general pathology of fever, with which the last chapters of the book are occupied, is treated in the same systematic and thorough manner as the subjects dealt with in the earlier parts of the book. A short but sufficiently full index is followed by an index of over 200 authors' names, a perusal of which latter is sufficient indication of the ground covered by Dr. Walker, whilst the book itself affords abundant internal evidence that at any rate the majority of these authors have been consulted first hand and in the original. A pleasing feature of the book, and one but too rare in works of this character, is the adequate acknowledgment of the part played by British workers in the elucidation of the problems connected with the subjects which give Dr. Walker the title for his book. In conclusion, we wish this little book the success that it deserves.

A Text-book upon the Pathogenic Bacteria for Students of Medicine and Physicians. By JOSEPH MCFARLAND, M.D., Professor of Pathology and Bacteriology in the Medico-Chirurgical College, Philadelphia; Pathologist to the Philadelphia Hospital and to the Medico-Chirurgical Hospital, &c. With 153 Illustrations, a number of them in colours. Fourth edition, rewritten and enlarged. London and Philadelphia: W. B. Saunders and Co. 1903. Pp. 629. Price 15*s.* net.

NUMEROUS as are the text-books of bacteriology, especially by American authors, which have appeared in recent years, a new edition of the present work may yet be welcomed heartily. The popularity of the book, evidenced by the need for a fourth edition within seven years, has "stimulated both author and publisher to endeavour in every way to make it merit continued approbation," and undoubtedly the efforts of both have been crowned with success. A detailed criticism of a work which has reached its fourth edition can hardly be necessary but it may be useful to point out in what directions this work differs from other text-books and the principal changes made in this new issue. In the first place, there is, as indicated in the title, a rigid exclusion of all micro-organisms which are not pathogenic either to man or to some of the lower animals and of all parasites other than those belonging to the group of bacteria. In the next place, it "is not to be mistaken for a laboratory guide," though, as a matter of fact, the descriptions of the principal methods of staining and other processes used in practical bacteriology are quite as fully and clearly described as is usual in text-books which profess a more ambitious aim. Throughout the methods described, however, there is always, as in the chapter on Sterilisation, a reference to the practical needs of the medical man, so that, as the author states, it is essentially a work for the use of physicians, students of medicine, and sanitarians. This new edition has been practically rewritten and much new matter incorporated but the addition to the contents has not increased the number of pages, as a smaller type, which, however, is still large and of excellent clearness, has been used. Other changes consist in the introduction of a large number of references to original papers and an index of authors. Certain errors in the description of Gram's method which were noted in the review of the second edition have been corrected and Van Ermengen's method of flagella staining has been inserted.

The book is divided into two parts. The first is occupied with general facts about bacteria and the technique of bacteriology while the second part deals with specific diseases and their associated bacteria. The growth of our knowledge of immunity has naturally necessitated a considerable extension of the space devoted to this subject which is treated clearly and judicially, though the space occupied in the consideration of rival hypotheses does not seem always to be commensurate with their relative importance. We could wish that some of the space occupied by Viquerat's lactic acid theory had been devoted to the "side chain" theory of Ehrlich, as this is treated in so brief and summary a manner that we fear the student will find difficulty in understanding it. Though it is quite logical that the consideration of natural immunity should precede that produced experimentally yet as the facts bearing on this latter condition are so much the more numerous and definite there are distinct advantages in reversing the order of treatment. Similarly it is difficult for the student to grasp the multitude of apparently contradictory facts with which the hypotheses of immunity deal until he has studied the pathogenic organisms and their results in detail and it will not be until Part II. of this work has been mastered that the full value of the earlier chapters of Part I. will be realised.

Part II. is distinguished by its method and orderly arrangement. Each chapter begins with what may be described as a definition of the organism which is therein treated and each organism is studied in a series of paragraphs, with headings in larger type, which follow each other in definite and, so far as is possible, invariable sequence. This makes for clearness. The whole of the second part is excellent and the points of practical interest to the medical man are well brought out. Some erroneous statements as to the action of antiseptics on anthrax spores which occurred in the second edition have been altered.

The book includes chapters on the Bacteriology of Air, Soil, Water, and Some Foods. The space devoted to these subjects, though small, is quite as great as, in the present unsatisfactory state of our knowledge of these departments of bacteriology, is required in such a work. There are numerous illustrations which, like the rest of the book, are well printed. They are taken from various well-known sources and, the author remarks, are "surely superior to anything new covering the same ground."

LIBRARY TABLE.

Slight Errors of Refraction and their Influence on the Nervous System. By C. ERNEST PRONGER, F.R.C.S. Eng., Harrogate: R. Ackrill. 1903. Pp. 31.—Our readers will recollect the publication of Dr. G. M. Gould's views as to the profound and far-reaching effects produced on a person's general health by the existence of visual defects. Particulars will be found in Dr. Gould's paper on the Ill-health of Richard Wagner, which appeared in THE LANCET of August 1st, 1903, p. 306. More recently—namely, in THE LANCET of April 30th, 1904, p 1181, Mr. Simeon Snell has dealt with the same theme in a paper on Eyestrain as a Cause of Headache and other Neuroses. Mr. Pronger's monograph is a reproduction in book form of a paper read by him before the Harrogate Medical Society in March, 1903, and the illustrative cases quoted in it show that the author, who is ophthalmic surgeon to the Harrogate Infirmary, has for the last ten years been studying the remote effects of eyestrain. Headache, insomnia, nervous disturbances in children, vertigo, depression, and abnormal irritability are some of the ailments which he has traced to this cause, with the result that the wearing of appropriate spectacles gave immediate and complete relief.

Notes on the Treatment and Filling of Teeth. By W. CASS GRAYSTON, L.D.S. Second edition. London: The Dental Manufacturing Co., Limited. 1904. Pp. 254. Price 5*s.* net.—The dental practitioner will find much useful information in this little book. The author does not pretend to deal with his subject exhaustively but rather aims at referring to certain practical points which he himself has found of value and he very wisely remarks that it is the man and not always the method that makes success. A point clearly emphasised and worthy of the attention of the young practitioner is that the ideal is not always possible and that the patient is a factor to be considered in the treatment of a tooth. In places we might feel inclined to challenge some of the statements made and this is more especially the case in the chapter on the relief of pain; there is in this section apparently a lack of knowledge of pathology and general surgical principles.

What we Owe to Experiments on Animals and *The Case against Antivivisection.* By STEPHEN PAGET. London: The Scientific Press, Limited. 1904. Pp. 72 and 104 respectively. Price 1*s.* 6*d.* and 2*s.* respectively.—The facts that are briefly stated in the first of these well-composed pamphlets have already been published by the author at greater length and with more references in a book called "Experiments on Animals" (John Murray, 1903). A short summary of the facts is given in this issue which will be useful to anybody who wishes to know what has really been gained by the help of experiments on animals in physiology, pathology, and practice. The evidence adduced by the author ranges over the following subjects:—The discoveries connected with the circulation of the blood by Galen, Realdus, Harvey, and Malpighi; the discovery of the lacteals and lymphatic system by Asselius and Rudbeck, and of the functions of the gastric juice by Réaumur and others; the discovery of the glycogenic function of the liver by Claude Bernard; the experiments made by Galen, Sir Charles Bell, and Magendie on the nervous system; the contrast between the work of the great clinician Semmelweis in the General Hospital of Vienna and that of Pasteur in his laboratory in connexion with inflammation and puerperal fever; and the work of Lord Lister. The author also summarises what we owe to experiments in the treatment of anthrax, tubercle, diphtheria, tetanus, rabies, cholera, plague, typhoid fever, malaria, and yellow fever. A summary of the Act relating to experiments on animals (39 & 40 Vict., c. 77) concludes this pamphlet which should be read by all those who are interested in the progress of scientific medicine and its relations with experimental research. In the second pamphlet, the author states that he hopes against hope that his work will not give grave offence where no offence is intended, but he is bound to be aggressive even though he keeps close to the subject, which comprises the methods, literature, and arguments of the antivivisection societies. His essay is concerned with them and with nothing else. In putting the case against these societies the author writes: "It comes to this, that the medical sciences are a system of natural sciences, bound to make use of experiments, fallible, dependent on other natural sciences, and set to find and prove facts that will stand the test of time. Such a fact may, or may not, come straight out of the experimental method, and it may, or may not, go straight into the practice of medicine." Mr. Paget traces the history of the antivivisection movement. The dates show that the oldest of these societies came after the Royal commission of 1875, not before it; the first societies and the Royal commission were alike the expression of a widespead opinion 30 years ago that experiments on animals ought either to be forbidden or to be restricted. He details the policy of these societies, how they are divided into two parties—the one asking for restrictions, the other for nothing short of abolition—and brings out how this division between them and the tone of the National Society towards the smaller societies waste their energy and their funds and hinder them from working together. These societies during the last quarter of a century have published a vast quantity of literature. Mr. Paget examines the style of this literature during the past few years and the arguments which it puts forward. He also examines the attitude taken by these societies towards certain problems and interests that closely concern them—viz., towards sport, towards the medical profession, and towards the hospitals. He writes: "They do not hesitate to take advantage of all those improvements of medicine and surgery which have been made by the help of experiments on animals. They denounce the work of the present; but they enjoy all the results of the past, and will enjoy all those of the near future." Mr. Paget's pamphlets render good service in recording succinctly the knowledge that has been derived from experiments on animals and in stating the case against antivivisection in convincing words and well-arranged sections.

The Meaning of a Modern Hospital. By W. BRUCE CLARKE, M.B. Oxon, F.R.C.S. Eng., surgeon to St. Bartholomew's Hospital. London: Longmans, Green, and Co. 1904. Pp. 47. Price 1*s.*—This small book is an enlargement of an address which the author gave at the Abernethian Society of St. Bartholomew's Hospital some two years ago. The address was printed in the *Hospital Journal* and this present issue is the outcome of a number of inquiries which have been addressed to the author and a request that it might be published. In doing so the [illegible] may appeal not merely to those of the [illegible] are specially interested in the construction and well-being of hospitals but also to that somewhat larger class, the governors of, and visitors to, hospitals who are often called upon by their medical staff for certain improvements and are sorely bewildered as to why modern medicine and surgery require so many additions to the equipment which sufficed for their forefathers. Mr. Bruce Clarke acknowledges how largely he has drawn on the writings of Parkes, Galton, and Henry Burdett and how much he is indebted to them. On first glancing through the pamphlet, indeed, the reader wonders where the necessity for such a work arises, seeing that all the points touched on are to be found discussed in the many manuals on hygiene and public health that are now in the hands of the public. On reading the pamphlet carefully, however, we are struck by the excellent arrangement of the subject matter and the fulness of the detail. Here we have in a small pamphlet of 74 pages a thorough and well-arranged guide for the construction and internal arrangements of an up-to-date hospital, and remembering that the pamphlet is partly intended for non-medical readers we feel that it will meet a want and be of real use to those of the public who are interested in such matters and whose business it is to look after the well-being of these great public institutions. In turn the author treats of what a hospital is, the ward unit, ward accessories, the hospital pavilion, methods employed for cutting off one ward unit from other similar ward units in the same pavilion, the grouping of ward units together, the roof, grouping of the pavilions, isolation blocks, operating theatres, the warming and ventilation of the hospital, pathological department, sterilisation of surgical dressings, residents' quarters, nurses,' out-patient accommodation, and supervision. We cannot agree with Mr. Bruce Clarke that it is good or right to allow the sister of a ward to sleep in the room provided for her adjoining the hospital ward. No doubt being constantly in touch with her work does give her a greater interest and hold over her ward than can be the case when she sleeps at a distance from it, but at what an expense the gain is derived. We think that the sisters and nurses are better housed in separate buildings and that in this way their health of mind and body is better maintained.

VICTORIA INFIRMARY, NORTHWICH. — Mid-Cheshire's memorial to the late Queen is to be the extension of the Victoria Infirmary, Northwich. The erection and equipment of the extension are to cost between £4000 and £5000, and it was intimated the other day that Messrs. Brunner, Mond, and Co. have promised to give £1000 to the fund being provided.

THE LANCET.

LONDON: SATURDAY, JUNE 11, 1904.

Hospital Sunday.

ON Sunday, June 12th, appeal will be made on behalf of the hospitals of London to the congregations assembled for worship within and without the metropolitan area, wherever those in authority are willing to hold collections for this noble cause. Again the hospitals through the agency of the Metropolitan Hospital Sunday Fund solicit alms on behalf of the suffering poor and again we are called upon to make public their needs, to call attention to their indebtedness, and to insist on their good claim to the bounty of the charitable. In 1903 the collection made by the Metropolitan Hospital Sunday Fund amounted to the record sum of £64,975, of which £15,766 ranked under the heading of *special donations.* *On the only two other occasions upon* which a sum exceeding £60,000 has been collected the special donations were £16,307 and £21,990 respectively, so that the splendid total of last year was an achievement of which the anonymous givers who contribute to the offertory as well as the special donors of large sums may be justly proud. It rests now with the congregations who worship in church, chapel, and synagogue, and upon their friends who may not be present in person, to see that the record of 1903 is beaten by that of 1904 and that the steady progress which the Fund has made since its first effort in 1873 may continue without interruption. The hospitals have not only to struggle in order to meet the liabilities which the absence of fixed incomes necessarily imposes upon them and in order to maintain their efficiency in the districts which immediately surround them, but they have to meet the demands of a resident population which steadily and rapidly grows larger by the influx of precisely that class of needy, or more often destitute, workers whose choice in time of serious sickness or injury lies between the hospital and death. Besides this, increased facilities for travelling, the appreciation by the poor of the benefits obtainable, and other causes bring to the hospitals of London patients from all parts of the kingdom and often from localities in which no contribution is made to the metropolitan institutions through the Metropolitan Hospital Sunday Fund or otherwise.

Reference to the increasing population of London naturally brings to mind the foreign population, to a large extent consisting of the poorer classes, which fills whole streets in some districts and the presence of which has recently excited considerable attention. We have no desire to enter now into what has to some extent become a political question but we may point out that the Metropolitan Hospital Sunday Fund subsidises the French, the German, and the Italian hospitals in the same proportion as it does all others which fulfil its conditions as to management and efficiency, and also that our English hospitals pay no more regard to nationality than they do to religious creed. In such circumstances we express the hope that none of those foreigners who find London a pleasant place of residence as well as a profitable one will forget that a large number of their countrymen struggle for a living in it and in time of sickness and accident partake of its charity. We are a nation at peace with all the great powers and the influence of our monarch has been and *is* being exerted to convert that peace into friendship where too little friendly feeling existed before. The foreigner profits with the Briton from the security which such friendliness imparts to their mutual relations and he cannot show his appreciation of the fact better than by recognising the claims of the hospitals of London upon his generosity, those hospitals in which the KING and his gracious Consort who shares his throne never cease to evince their deep interest. In expressing our sincere hope that the current year may witness a further augmentation of the receipts of the Metropolitan Hospital Sunday Fund we do not make reference to the poverty of individual hospitals. The success of the Fund is largely due to the efforts of its organisers to insure that its distribution shall be in accordance with the efficiency of the institutions assisted. It is not enough for a hospital to show that it is poor; it must also show that its poverty is met with an honest front and must demonstrate the business-like efficiency of its administration. In insisting upon the necessity of carefully kept accounts readily to be understood by those wishing to examine them the Metropolitan Hospital Sunday Fund has strengthened its own position and that of each hospital which through its influence has adopted the methods recommended.

The benefit accruing to the wealthier classes from the support which they bestow upon the hospitals for the sake of their poorer brethren must not be forgotten by them. It is not limited to aid afforded in the case of accidents occurring in the neighbourhood of hospitals but consists, as the LORD MAYOR in the letter which we publish at p. 1684 aptly reminds us, in "incalculable services to those who can afford to pay for the experience gained within their walls." This is a matter to which the public may well direct its thoughtful attention. We who live in the year 1904 are familiar with conditions which to our ancestors of even a century ago would have seemed well-nigh miraculous. Vaccination has almost banished small-pox from our midst and would stamp it out completely for us did we only give it a full opportunity to do so. *Operations are performed in circumstances of* anæsthesia and asepsis which the most indifferent layman must realise to have been formerly not only impossible but inconceivable. But does the layman realise how much of this is due to the hospital or how much of the skill involved in the individual act of surgery has been acquired in these noble institutions and would not have been gained without them? Although the present age is one of progress and of considerable public and popular interest in the discoveries of science the public is curiously prone to grasp at shadows. The ills *of human life are matters of discussion* in the lay press and, to take two prominent instances, "cures" for cancer and consumption are being continually announced as accomplished facts. It is a question whether the larger public which should support the hospitals, and without whose universal support the hospitals live a precarious existence from day to day, fully realise that in the hospitals alone the saving measures which they so eagerly desire can ever be brought within the reach of suffering humanity. They too often ignore or forget the fact that such discoveries as are necessary before fell diseases can be dealt with by medical science are not the result of inspiration or of speculation. They are born of close observation of diseased conditions in all their varieties and of ceaseless study and interchange of knowledge such as are possible only in the wards of our hospitals and in the laboratories attached to them. It is not, however, for the sake of benefits some day to be enjoyed by themselves, or possibly received already, that we would urge all to give on Hospital Sunday but rather in order that their poorer brethren may be succoured by their generosity and may bless the kindly charity of the known and the unknown givers.

The Influence of the Unrecognised Case in the Spread of Communicable Disease.

With the advent of fresh administrative measures for the control of an infectious disease, no less than upon the discovery of fresh scientific facts about the disease, enthusiasts are apt to arise and proclaim that the application of such measures or the influence of such discoveries will result in stamping out. Time alone suffices to cool their ill-directed ardour, but time supplies fresh enthusiasts to re-enact the drama in connexion with other measures and other diseases. When Jenner discovered that vaccination was protective against small-pox he was led away by his enthusiasm to assert that such protection was lifelong before the time necessary to furnish the essential evidence had elapsed. It required experience to satisfy all fair-minded persons that the prophecy was not fulfilled and that to complete protection revaccination was necessary. And now vaccination has to bear the brunt of the original over-statement. With the introduction of the isolation hospital there came from unbalanced extremists somewhat similar prophecies. Infectious diseases, by means of these admirable institutions, would be "stamped out." Again the testimony of experience has cooled their ardour or convinced them of their error. When in 1889 the Infectious Diseases (Notification) Act was passed the machinery for dealing with infectious disease was thought to be complete and the only thing necessary to extinguish the diseases to which the Act related was to make the measure general throughout the country. This has now been done; but nevertheless considerable leakage in connexion with scarlet fever and diphtheria still ensues. And finally tuberculosis has received the attention of the enthusiast. According to some of those who figure prominently in the crusade against the "great white plague" the disease may be "stamped out" by sanatoriums alone; according to others compulsory notification is required; others again think that the prohibition of promiscuous expectoration would precede abatement of all forms of the disease. Since pulmonary tuberculosis is steadily declining in this country, and is likely ere many decades have passed to become extinct, it may be difficult to disprove some of the extravagant claims made in these directions, more especially as the promoters of the several panaceas seem to keep carefully in the background the fact that the disease has been steadily declining for years past and long before any direct measures against it were taken. The fundamental error underlying the fallacious beliefs and unfulfilled prophecies to which we have referred is the tendency to assume too readily that we know the whole truth with regard to the numerous and complicated factors which make up what we term "disease," and it is against this misleading conception that we have in recent years endeavoured to protest in the pages of The Lancet. One result of the over-statements in question has been the uprising of numerous anti-bodies, if we may apply this bacteriological phrase to agencies directed against the establishment of vaccination, the erection of isolation hospitals, and the provision of other unquestionably useful preventive measures and institutions. There has been in the past too great a tendency to overlook the fact that the greatest victories of public health have been what may be termed indirect victories. That is to say, that the diseases which have either vanished or are apparently in process of disappearance are those against which few direct measures have been taken. Perhaps the best illustration of this fact is the case of typhus fever, the organism of which has not yet been definitely isolated and concerning the natural history of which disease we know but little. We know, however, that the malady flourished in the overcrowded hovels of the poor where filth and poverty held sway. Now the disease is almost extinct in this country. A somewhat similar observation may be made with regard to relapsing fever and plague, while the best instance of the dying disease of the present day is that of pulmonary tuberculosis.

These reflections lead us to ask why it is that greater success has not hitherto attended our direct efforts—why it is that in spite of our compulsory notification and our isolation hospitals scarlet fever and diphtheria are still with us in a material and disturbing degree. We are not prepared with a final answer nor are we desirous to add yet another unfulfilled prophecy to the instances which we have already quoted. But there can, we think, be little doubt that a potent factor in promoting the persistence of these two diseases is the very large number of cases of each which entirely escape recognition. The medical officer of health is too prone to believe, when he has taken a map, has blocked out on it all the notified cases, and arranged them in groups according to the milk-supplies or the schools attended, the whole story is before him. But what a different story a medical man, specially trained in the various manifestations of scarlet fever, might bring back could he make a house-to-house inspection of the district and carefully examine the inmates. Or, supposing diphtheria to be the disease in question, how might the map become modified could the bacteriologist examine the throats of all those both inside and outside, the invaded area. What, too, would be the bacteriologist's story were he able to examine all the articles in the houses in which cases of diphtheria had occurred, houses which had been through a process of disinfection in so far as the room occupied by the patient after the disease was recognised? We are glad to see that Dr. ARTHUR NEWSHOLME drew attention to the importance of the unrecognised case in a lecture which he recently delivered at Victoria University, Manchester. There can be no doubt that the necessity of searching out suspicious or unnotified cases, which has so long been insisted upon in the memoranda of the Local Government Board, is not adequately acknowledged in the public health service generally, notwithstanding the fact that the progress of bacteriology has rendered such search all the more promising and all the more necessary. Anyone with experience of epidemiological investigations will easily recall instances where whole households have been notified on a given day and where the appearance of the individual cases was such as to leave no doubt of the fact that the cases had occurred at different dates. Dr. NEWSHOLME pointed out that the onus of a mistaken diagnosis is so great that medical men hesitate to act at the moment when the information which they might give would prove of maximum value to the medical officer of health. Obviously it is difficult for cases to be recognised and isolated the very moment when they become infectious—and precisely when this is we are by no means clear—but unless this can be done there may be very grave obstacles in the way of "stamping out" any given outbreak by means of notification and isolation alone. Fortunately, in connexion with certain diseases our preventive measures are becoming simplified by the progress of protective inoculation, and although we can hardly look forward to such brilliant results in the case of all diseases as have attended our efforts with respect to small-pox and diphtheria we may, perhaps, reasonably hope that temporary immunity from attack may ere long be attainable in connexion with several diseases.

But if advantage of modern knowledge is to be taken there must be a considerable expansion of the department of the medical officer of health. It is not feasible to make use of the sanitary inspector in the matter of diagnosis, hence if suspicious cases are to be sought out diligently properly trained assistant medical officers of health must be employed. Moreover, there must be greater facilities afforded for the employment of bacteriology as an aid to epidemiology, and more inducements must be offered to medical practitioners to make use of such facilities in connexion with doubtful cases. All this means increased expenditure both of time and money, but it is as well that the public should appreciate this fact: that if they desire the maximum use to be made of notification and of isolation hospitals a more earnest effort than heretofore must be made to discover the unrecognised case. Moreover, more extensive powers must be procured for the control of "contacts" and for the temporary seclusion of those who may be found to be harbouring pathogenic bacteria in their throats or elsewhere, though the yoke must not be made too vexatious at first, for the public coöperation will be wanted. A careful study of the conditions which have led almost to the extinction of typhus fever and to the decline of tuberculosis in this country may perhaps help us to make greater resistance to other infectious diseases.

Periodic Hydrarthrosis.

THE writings of Professor HOWARD MARSH have always been characterised by an especial degree of lucidity and accuracy which have greatly contributed towards the ready adoption of any new views which he has put forward from time to time. The volume of collected lectures which he published a few years ago bore eloquent testimony alike to his extensive experience and his knowledge of contemporary scientific literature, and the medical profession always awaits his words with interest. Great service can be rendered to surgery by men who occupy high positions in its pursuit when they give to the profession the fruit of many years of observation to assist in the recognition of morbid processes heretofore undescribed. It is for this reason that we welcomed heartily in our columns Professor MARSH'S Hunterian lecture, delivered at St George's Hospital on May 25th and printed in our issue of June 4th, for it dealt with a very obscure condition. Very little is known of intermittent hydrops articuli but it is probably by no means so rare as might be thought. The text-books are silent but here and there scattered about in surgical literature lie many cases which may confidently be included in this category without counting many others about which doubt may reasonably be felt. Professor MARSH by his lecture will assist other observers to diagnose the condition, and with a larger number of cases collated more definite knowledge may be obtained.

The earliest case recorded appears to have been under the care of VEILLARD in 1857, but others which were earlier were quoted at a discussion at the Société de Chirurgie of Paris after PANAS had described a case in the year 1878. Professor HOWARD MARSH has described two cases, each of which had some noteworthy points. In one there was a definite history of injury, where, three months after an apparently complete recovery, pain returned in the knee and with intervals lasted for many months. At first there was no perceptible swelling but later swelling was present and was especially obvious at night. The periodicity was very well marked, for regularly every evening the patient's knee became swollen and painful and every morning it returned almost to the normal. In the second case the joint affected, which was also the knee, became very swollen every fortnight and the swelling lasted three days and then subsided. Here the regularity of the recurrence was very exact. From an examination of some 45 cases which have been recorded it is seen that the joint most frequently affected is the knee, and this might have been expected, for as the condition is clearly an affection of the synovial membrane and as the knee has by far the greatest extent of synovial membrane, we should anticipate that the knee would be likely to suffer most frequently. Both knees may be affected and the disease may be confined to this articulation, but any of the large joints may be involved. In some cases the affection is limited to the joint first attacked; in others it passes in succession from one joint to another. The duration of an individual attack may be very short, in one of Professor MARSH'S cases it did not exceed 15 hours, but in the average case each attack lasts four days, half of this time being occupied in the progress of the swelling and pain and half in the subsidence of the symptoms. The interval between the commencement of successive attacks were most commonly a fortnight and it is curious how frequently in the accounts we meet with this degree of frequency of return. But the intervals may be very short, as in one of Professor MARSH'S cases where the exacerbations appeared daily. In some the intervals vary greatly. In one case described by PLETZER the attacks occurred irregularly at first, later they came on every three months, and later still an attack appeared every fortnight. In PANAS'S case the first attack appeared in a woman a fortnight after delivery and lasted four days; subsequent attacks came on once a fortnight and regularly on a Monday. The disease lasted four years and during this time the patient bore two children; and it is interesting to note that during the pregnancies the attacks were suspended. The local lesion is not absolutely identical in all the cases. In most there is definite, and often extensive, effusion into the synovial cavity but in others the chief change appears to be a thickening of the synovial membrane itself and this membrane is always thickened to some extent in cases which have lasted long. In the same case at one time there may be much effusion and at another the thickening of the synovial membrane is more in evidence. On the whole more women are attacked than men and the disease is rare before puberty. Occasionally there has been noticed a coetaneousness between the attacks and the menstrual periods but it is not unlikely that this was a mere coincidence. The treatment cannot be said to be satisfactory. In a number of cases the joint has been aspirated and a little of the fluid withdrawn for examination. It has never been found to be purulent but is always a thin synovia. In a few cases a bacteriological examination has been made and in all but two of those examined the fluid has been found to be sterile, and it is not improbable that in the two exceptions there had been accidental contamination. In a few cases the administration of quinine has been followed by a complete or partial disappearance of the swelling and pain, and one of Professor MARSH'S two cases proved a good instance of the value of quinine. In other cases arsenic has proved of great utility. Both of these drugs have failed, and failed utterly in many cases, but their marked success at times is such as to justify their routine employment in any case met with of this nature. No other treatment appears to be of any use.

When we approach the question of the etiology of intermittent hydrarthrosis we are confronted with the great difficulty that we have so very few facts on which to build a theory. The value of quinine and arsenic suggests that the condition may be malarial in origin, and, indeed, in several of the cases there has been a definite history of malaria. The undoubted failure of these drugs in still more cases shows that the association with malaria is probably not causal. The rapid appearance of the swelling and the equally rapid subsidence suggest that the lesion is vaso-motor in origin and therefore dependent on a disturbance of the nervous system, and this view is supported by the frequent occurrence of neuralgia in many of the cases. In one instance exophthalmic goitre was also present and this is also suggestive of a nervous etiology. Professor MARSH aptly quoted in his lecture three cases of periodic vomiting, described by JOSEPH ADAMS in 1815; two of these recovered under treatment with arsenic. These cases appear to bear some analogy to those of intermittent hydrops and, on the whole, it may be said that the nervous theory of origin has much to support it. Fuller knowledge of the disease can only be achieved by a wide observation of cases and now that the affection has been so clearly brought to the notice of the profession by Professor HOWARD MARSH it may be hoped that instances of it will be recognised, examined, and described.

Annotations.

"Ne quid nimis."

THE CHAIR OF PATHOLOGY IN THE VICTORIA UNIVERSITY.

DURING the last few years a large amount of bacteriological and other scientific work has been done for various sanitary authorities in Lancashire and Cheshire by the public health laboratory of Victoria University, Manchester. That the investigations and the resulting reports have been highly appreciated is sufficiently shown by the progressive increase in the work, for whereas there were 1504 such subjects reported on in the year 1897, there were 4652 in 1900, and 5220 in 1901. The laboratory is one of the divisions of the bacteriological department of the Owens College and was originally intended only for use in connexion with teaching, but the result of subsequent developments was to make it a well-recognised place of reference in matters relating to infectious diseases. The rapid increase of work rendered necessary in succession the appointment of laboratory assistants, the removal of the laboratory to larger premises, and the appointment of an assistant lecturer in the pathological department to relieve the professor of pathology of part of his routine teaching duties. A more important change was initiated in the summer of 1903, when it was decided to apportion the work of the existing chair of pathology between two new chairs—namely (1) a chair of pathology and pathological anatomy which would deal with the subject as needed by medical students preparing for medical qualifications; and (2) a chair of comparative pathology and bacteriology dealing with pathology from the public health point of view, the courses given by the incumbent of that chair being intended for advanced and public health students, including veterinary surgeons preparing for qualifications in veterinary State medicine. The directorship of the public health laboratory is also attached to this latter chair. The existing Procter chair of general pathology and morbid anatomy has been held since 1891 by Professor Sheridan *Delépine* who, we understand, will for the future carry on the duties of the chair of comparative pathology and bacteriology. The chair of pathology and pathological anatomy is therefore vacant and as announced in THE LANCET of May 28th applications from intending candidates will be received up to June 27th. It is stated that two local candidates—Dr. I. Walker Hall and Dr. F. C. Moore—well known both as pathologists and as teachers, are already in the field. The foundation of a chair of comparative pathology marks a new departure in connexion with medical education in this country and the Victoria University is to be congratulated on the step forward that it has taken. By the new arrangement the professor of pathology and pathological anatomy of the medical student.

THE NATIONAL SOCIETY FOR THE PREVENTION OF CRUELTY TO CHILDREN.

The annual meeting of the National Society for the Prevention of Cruelty to Children was held on May 18th The report for the past year is in most respects a satisfactory one. It is significant that the number of prosecutions is steadily diminishing and is 136 below that of last year, warnings to offenders having proved more effective than formerly. The one discouraging feature in the society's record is its financial position. It is true that the amount derived from annual subscriptions is greater by £566, while the cost per child protected has fallen from 13*s.* 5*d.* to 13*s.*

nevertheless £1301 under
diture amounts to £67,919,
e of £4818. When this is
£10,884, the total liability

of the society amounts to £15,702. The executive council is not indifferent to the meaning of these figures. Special efforts in the form of bazaars and fêtes have been organised with a view to increasing the deficient revenue and not without success. On the other hand, the necessity of stringent economy is fully recognised. It is proposed to reduce as far as possible expenditure on publishing which in certain branch districts appears to have been carried out on a somewhat liberal scale. Legal and medical expenses will also be reduced. Solicitors and medical men will only be applied to when their services are *indispensable and payment will be made upon a basis* previously arranged and notified. There is no desire, as far as we can gather, to minimise the value of professional assistance and we cannot blame the society for conducting this department of its work with an admission of the limitations imposed upon it by the amount of means at its disposal. The coat must be cut according to the cloth and provided that their remuneration is adequate medical practitioners are not likely to complain because it is not excessive.

GARBAGE AND POISONOUS MEAT.

Dr. George Newman, the medical officer of health of the borough of Finsbury, laid some very interesting items of information before his health committee on June 7th. For instance, on May 11th, Mr. Ralph Lustig of 26, Chapel-street, was fined at the Clerkenwell police-court upon two summons for depositing and exposing for sale 29 pieces of beef intended for the food of man which were unsound. Mr. Lustig was fined in all £6, a paltry sum when the seriousness of the offence is considered. From May 6th to June 2nd there were confiscated in Finsbury 3347 pounds of diseased and unsound meat, to say nothing of such cheering items, as 253 sheep livers affected with fluke and hydatids, 69 beef livers with hydatids, flukes, and tuberculosis, and 22 beef lungs with hydatids and tuberculosis. The quantity is large for one borough and is probably due to the presence of the offal shops which congregate just outside the Central Meat Markets. One case of doubtful meat, however, is so important that it deserves special mention. On March 11th one of the sanitary inspectors, by name Billings, brought to

, although not showing
factory. Dr. Newman
A. G. R. Foulerton for

were rapidly killed by small doses of cultures of this

[illegible] The meat was hung in a moderately dry atmosphere until April 19th when it had shrunk to a certain extent but still there was no putrefaction. Only the Gaertner bacillus could now be found and this retained its virulence. Mr. Foulerton further pointed out that this bacillus has upon many occasions been shown to be the cause of so-called "ptomaine poisoning" and of meat borne outbreaks of illness and Dr. Newman continues :—

> It is true that in the ord
> probably be destroyed, but

Meat of this class is exceedingly dangerous and very difficult of detection and we think that Inspector Billings deserves every credit for his acumen.

TUBERCULOUS MENINGITIS IN ADULTS.

The clinical description of tuberculous meningitis is based upon cases observed in children, in whom the disease is most common. The *Boston Medical and Surgical Journal* of May 12th contains a valuable paper by Dr. H. Jackson on Tuberculous Meningitis in Adults. He finds that the symptoms differ markedly from those of the disease in children. The paper is a study of 18 cases observed at the Boston City Hospital in the last few years. Seven of the patients were between the ages of 18 and 25 years, eight between 25 and 35 years, and three between 40 and 45 years. In three cases there was a previous history of a subacute disease two years before admission, which suggested preceding tuberculous disease—namely, in one case pleurisy, in one a cough which lasted a long time and kept the patient in bed, and in the third case some disease that kept the patient in bed several weeks. In one case no history was obtainable and in the remaining 14 cases there was no history of a preceding illness. Therefore in the diagnosis of tuberculous meningitis the absence of evidence of a preceding tuberculous disease is of little weight. On the other hand, in only two cases did the necropsy fail to reveal old healed tuberculous lesions but in none was there extensive disease capable of diagnosis during life. The period of illness before admission was much shorter than in children. One patient was admitted as a case of sunstroke with the history of sudden unconsciousness, one had complained of sore throat for two days, one had been ill for two weeks, three for a week, and seven for ten days. In one case the patient had been ill with vomiting and diarrhœa for four weeks. In only three cases was there a history of symptoms lasting several weeks and in these there was general, in addition to meningeal, tuberculosis. The prodromal symptoms in all were indefinite and suggestive of many acute fevers rather than of cerebral disease. In only four cases was stress laid on headache or vomiting though slight headache was present in others. Three patients were delirious and in the case of one insanity of some form was suggested. The general impression made by the cases may be gathered from the fact that in most of them Widal's test was performed. The course of the disease in hospital was that of some cerebral trouble. One-third of the cases presented the state described as "typhoid delirium" and two-thirds presented varying degrees of stupor and delirium. Headache was often admitted when the question was asked but in only one case was it severe. The kind of headache, photophobia, cerebral cry, and restlessness usually present in children suffering from the disease were absent. In two cases there were convulsions. In the first part of the acute stage the pulse was slow. The rate was usually from 60 to 70 until the last few days of the disease and occasionally was as low as 50. In the last two or three days of life the rate was from 130 to 150 and in a few cases even to 180. The temperature was unimportant, being usually from 100° to 101° and rarely over 102·5° F. In one case it was normal or subnormal. The leucocyte count was lower than in acute cerebrospinal meningitis. Of nine cases 23,000 were found in one, 17,400 in another, and in the remainder the number was below 12,000. Lumbar puncture was performed in eight cases. In all the fluid spurted out, showing that it was under pressure. The fluid was almost clear and contained a few flocculi. In one case the bacillus tuberculosis was found in it. The results were therefore very different from those obtained in acute cerebro-spinal meningitis, in which the fluid is purulent or semi-purulent and organisms are easily obtained on culture. Examination of the fundi yielded little of importance; in only one case was optic neuritis found. In three cases there was no paralysis but the patients were very ill and died soon after admission. In 12 cases paralysis was limited to one or more ocular muscles. Thus the rule was that paralysis was limited to the ocular muscles. In two cases there was slight facial paralysis in addition to strabismus. In one case there was extensive paralysis—left mydriasis and complete left hemiplegia. Other signs of cerebral disease, such as retraction of the head, Kernig's sign and opisthotonos (found only once), were less frequent and less marked than in cerebrospinal meningitis. After the onset of acute symptoms three patients died in less than three weeks and several in less than one week. The clinical and post-mortem examination of the lungs corresponded; in no case was a lesion found sufficient to give rise to signs during life. In 16 of the 18 cases small areas of chronic pulmonary tuberculosis or caseous lymphatic glands were found. Acute miliary tuberculosis of the lungs was present in seven cases and general acute miliary tuberculosis in five. The spinal meninges were involved in eight cases.

THE SUNSHINE OF ENGLAND AND SWITZERLAND COMPARED.

IN THE LANCET of May 14th, p. 1370, the sunshine recorded during April in Switzerland and the south of this country was compared and it was seen that the advantage was altogether with the latter. The figures for May, on the contrary, show that during that month the conditions were reversed, the only British station to approach the majority of those in Switzerland being Jersey, a spot which represents Normandy far better than it does England. The Swiss values were probably higher than they appear in the table, for the two days for which the records are not to hand may have been almost cloudless. All the home totals were much below those of a normal May, especially on the coast of Sussex, while it is curious that London, which had an excess greater than the other places in April, should have maintained its relative superiority by having a comparatively small deficit during May. The disproportion in the records from Switzerland and our own coasts is, of course, greater than it appears, as at this time of the year the sun is above the horizon a very appreciably longer time with us than is the case about 250 miles further south. Even in the more northern parts of these islands, where the duration of daylight is greater than on our south coasts, the sunshine was less than that registered during April. Aberdeen had 145 hours, *Harrogate 128, Nottingham 136,* and Birmingham 133. The most sunny of the Swiss resorts was again that situated near the borders of Italy, Lugano, and this was followed at a respectful distance by Berne, the elevated Davos, and Zürich. The station with the greatest altitude (Santis) had the least sunshine, but even that was equal or superior to any of our own resorts excepting Jersey and Torquay.

May Sunshine in the South of England and in Switzerland.

CHILDREN'S COUNTRY HOLIDAYS FUND.

The Earl of Erroll and Lord Avebury have just issued a letter of appeal on behalf of that large and important section of our population, the 800,000 children under 14 years of age who fill the elementary schools of London and West Ham, the majority of whom do not leave London *for a holiday* in the country or leave it *for a single day's excursion only.* It is the object of the Children's Country Holidays Fund to place within the reach of children of either sex and every creed whose parents are willing to assist the opportunity of obtaining the permanent physical and moral development which is fostered by residence amid new surroundings and by a glimpse of nature and of country ways. The fund has, except in a few cases, adopted the plan of boarding out London children with country cottagers. In 1903 over 34,000 children were sent to country friends in this manner, the cost per head being about 14*s.*, including railway fares. But the work is always growing and larger expenses can only be met by more liberal help. The fund is doing more and more each year to provide for a very real and urgent need and it is for this reason that the Earl of Erroll and Lord Avebury once more appeal to the public to assist. Cheques should be made payable to the Treasurer, 18, Buckingham-street, Strand, W.C.

BLOOD CHANGES PRODUCED BY ETHER ANÆSTHESIA IN MAN AND THE LOWER ANIMALS.

IT has been known for some time that the inhalation of ether and consequent entry of ether into the circulating blood are followed by blood changes chiefly of the nature of hæmolysis. A careful paper by Dr. J. M. Anders and Dr. L. N. Boston of Philadelphia, which space does not permit us to print in full, details experiments bearing on this point that have been performed upon animals and observations made upon the human subject with regard to the same question. The subjects of investigation were in the case of human beings patients undergoing comparatively slight operations or else persons inhaling ether purely for the sake of the investigation. Earlier research has shown that the fall in hæmoglobin in ether anæsthesia reaches its lowest level 24 hours after the termination of the anæsthetic state, one half of the fall *taking place during the first* hour after anæsthesia and the other half during the next 23 hours. Dr. Anders and Dr. Boston find similarly that hæmoglobin is reduced in every instance as the result of ether anæsthesia, that the reduction varies according to the length of the inhalation, that 10 per cent. of the reduction takes place during the first 20 minutes of the inhalation, and that hæmoglobin reaches its lowest level at from 24 to 30 hours after the termination of the anæsthesia. There is less decided loss during a second administration conducted soon after the first and the reduction is more quickly recovered from. Changes in the red cells are always present after the anæsthetic state is reached, the individual cells being thick and compact. Leucocytosis occurred in two-thirds of the animals experimented upon. In human beings the leucocytes were sometimes increased and sometimes diminished, always returning to the normal number soon after the cessation of anæsthesia. Myelocytes in small numbers appear in human blood after ether anæsthesia. As regards hæmoglobin Dr. Anders and Dr. Boston find that the colour index reaches the normal 72 hours after the cessation of anæsthesia. In general terms it may be said that etherisation produces increased hæmolysis, followed by rapid regeneration of cells with increased number of red corpuscles.

THE HEREDITARY TRANSMISSION OF ALKAPTONURIA.

Dr. Archibald E. Garrod sends us the following interesting note:—"In the *Gazzetta Medica Lombarda*, 1889, vol. xlviii., p. 115, Professor Francesco Orsi of Pavia gave an account of 'Tre individui di una stessa famiglia colpiti da Pirocatechinuria,' and on p. 135 of the same volume his assistant, Dr. Cesare Magni, has a further communication. 'Sulla Pirocatechinuria.' These papers have hitherto escaped the notice of those of us who have collected the recorded cases of alkaptonuria. The very full description of the urine given includes practically all the characteristic features of alkaptonuria, such as the darkening on standing or on addition of an alkali, the reduction of Fehling's solution, the negative result of the bismuth test for sugar, and the absence of rotation of the polarised ray. The attribution of its properties to the presence of pyrocatechin was merely a reflection of the views prevalent at the time and Dr. Magni mentions alkaptonuria as an alternative name for the condition. In the absence of any direct evidence that pyrocatechin was the abnormal substance present in these cases we are justified as classing them as examples of alkaptonuria. The first patient, Signor C. S., aged 20 years, was brought to Professor Orsi by his cousin, a medical student, on the supposition that he had diabetes. Professor Orsi goes on to say: 'I had occasion later to analyse the urine of Signorina R. S., a sister of Signor C. S., and found it to resemble that of her brother. Moreover, I have been assured by the student, Signor F. S., that the urine of the mother of Signor C. S. and Signorina R. S. also presents the main characters of that of her children.' Although a large proportion of alkaptonurics are brothers and sisters, only one other instance of the direct transmission of the anomaly from parent to child is known—namely, in the family under Professor W. Osler's observation[1] in which a father and son and a brother of the father have exhibited the peculiarity. The fact that this hitherto overlooked record affords a second example is my excuse for calling attention to it in the present note." Dr. Garrod, as is well known, writes with authority on the subject of alkaptonuria and its literature, having himself also worked at the chemical relations of this peculiar substance. The above addition to the scanty number of cases on record is of great interest as an example of the hereditary transmission of the condition and also as indicating that some cases may have escaped notice, the reduction of Fehling's solution being attributed to some other substance such as pyrocatechin or sugar. It is also a point worthy of notice that several of the rarer anomalies of metabolism, such as pentosuria and cystinuria, as noted in another column (p. 1673), show peculiar family relations as do the more common metabolic diseases—gout and diabetes.

ASH AN ASSET.

As everybody knows the ash left on burning tobacco is considerable and, as a matter of fact, the mineral matter of the tobacco leaf frequently amounts to as much as a fifth part of its weight. Thus, a ton of tobacco leaf would yield four hundredweights of ash which represents valuable mineral constituents withdrawn from the soil which have to be replaced by abundant manuring. It has been calculated that a ton of tobacco withdraws over a hundredweight of mineral constituents per acre of land. In 1901 the home consumption of tobacco in the United Kingdom was at the rate of two pounds per head, or a total of about 40,000 tons, which represents, at what is now a probably low computation, approximately 8000 tons of ash annually committed to the winds or dissipated in some way or other. This would appear to be an astounding waste of material which must be of enormous value to the soil considering that 75 per cent. consists of calcium and potassium salts and 15 per cent. of magnesium and sodium salts, including nearly 5 per cent. of the essential constituent to all plants—phosphoric acid. On the face of it there would seem to be a fortune in store for that individual who could devise a successful means for the collection of tobacco ash, and it is great pity that so much valuable material should for ever be lost to the soil without any attempt at direct restoration being made. It means an economic loss which without artificial resources would ultimately starve and ruin the soil used in the production of tobacco. Ash after all ought to be a valuable asset in the economy of things. Similarly, in the form of animal excreta there is annually an enormous loss of material of the utmost value to the soil, although the time may not be far distant when we shall see even that economically restored to the land. The late Sir John Lawes once argued that the discharge of sewage into the sea did not necessarily imply waste for we had it back in the shape of a bountiful fish harvest, but the sequence of events is very doubtful.

JAUNDICE IN SECONDARY SYPHILIS.

THOUGH jaundice in secondary syphilis has been described by writers from Paracelsus downwards it does not seem to have received much attention in this country. It is certainly far from common, for Werner in the records of the Hamburg hospitals found only 57 cases of jaundice in 15,799 cases of secondary syphilis. In the *American Journal of the Medical Sciences* for May Dr. W. J. Calvert has reported the case of a man, aged 27 years, who was admitted to hospital on June 6th, 1902, with intense jaundice. Six weeks before a sore developed on the glans penis. On June 3rd the patient first noticed the jaundice. On admission there were intense jaundice, an indurated chancre, one enlarged right inguinal gland, and slight general glandular enlargement. There was no fever. The liver was of normal size and not tender. The urine contained bile pigments but the fæces were not decolourised. Three days later a general macular eruption appeared. The general condition of the patient was good; there was neither fever nor digestive disturbance. Under mercury and iodide the jaundice and secondary symptoms disappeared in three weeks. The pathology of jaundice in secondary syphilis is not settled. It has been ascribed to various causes—enlarged glands pressing on the bile-ducts, secondary eruptions in the intestines obstructing the flow of bile, congestion of the liver, and [illegible] diseases. Two types can be distinguished, a benign and a grave. In benign cases the jaundice develops rapidly without the usual digestive disturbances of catarrhal jaundice. In three-fourths of the cases the jaundice develops simultaneously with the secondary symptoms; in the remainder it develops either before or after them. In degree it varies from a light to a deep tint. Its course runs parallel to that of the secondary symptoms. It lasts from a few days to two months, but if treatment is neglected it may become chronic. The hypochondriac region may be tender. In two of Werner's cases the liver was enlarged. The urine has the ordinary characters of jaundice and the fæces are more or less decolourised. Pruritus is seldom present. Werner observed xanthopsia in three cases. In grave cases the jaundice first develops as in benign cases, but on the fifth or sixth day delirium, hæmorrhage, purpura, or coma occurs and death often rapidly follows. In an annotation we have recently described at greater length this form and related a remarkable case.[1]

THE REBUILDING OF ST. BARTHOLOMEW'S HOSPITAL.

ON the evening of June 3rd a concert in aid of the Rebuilding Fund of the Royal Hospital of St. Bartholomew was given under the auspices of Signorina Giulia Ravogli at Queen's Hall. The principal item of the performance was Gluck's *Orfeo* in which Signorina Ravogli of course took the title part. She was assisted by Miss Lydia Nervil as Eurydice and Miss Martha Cunningham as Amor. The choruses were sung by the members of the Leeds Choral Union and the whole performance was conducted by Mr. Alfred Benton. We are glad to say that the hall was well filled so that the funds of the hospital must have benefited to a considerable extent. Signorina Ravogli's rendering of the part of Orfeo is too well-known and too highly appreciated to be in need of any further praise here and she received every assistance from the other two principal singers. The choruses were sung with the attack and precision and the beauty of vocal tone for which the Leeds Choral Union is so well known. We cannot omit to give special praise to Mr. Albert Fransella's perfectly beautiful rendering of the flute part in the number entitled "Ballet of the Happy Souls," a melody which always seems to us as perfect an expression in musical terms of "Animula, Vagula, Blandula" as can be imagined. But Gluck's music is invariably in exact accordance with the feeling of the story which it illustrates. Mr. Malsch also deserves commendation for his playing of the hautboy obbligato to the air which follows almost immediately afterwards. After the performance of *Orfeo* the Leeds Choral Union sang two choral numbers by Elgar and Mendelssohn. Altogether the performance was most enjoyable.

VACCINATION IN BURMA.

IN the *Rangoon Gazette* of April 27th Dr. T. F. Pedley makes a very serious indictment of the management of the Provincial Vaccination Department of Burma. Briefly, his charges are that "a sufficient staff of competent honest vaccinators and a regular supply of good lymph" are not provided. In illustration of the latter complaint he states that in the Northern Shan States and Chin Hills the successful results in 1900-01 were officially given as 22·49 and 28·39 per cent. respectively. In Rangoon itself a vaccination depot for the production of animal lymph was established in 1883 and maintained until 1900, when the Government grant was withdrawn. Afterwards civil surgeons and district vaccinators were directed to obtain lymph from another station distant, as measured by [illegible] services. The lymph formerly provided in Rangoon had seldom or never failed even a month after its issue, but the new lymph is usually inert in a week or ten days and failures are frequent even earlier. As a natural result the Burmese are said to be losing confidence in vaccination, and resorting more and more to the ancient practice of small-pox inoculation. The diminution is officially acknowledged and the superintendent general of vaccination attributes it to three causes: (*a*) that outside municipal limits vaccination is not compulsory or small-pox inoculation illegal; (*b*) that in the past the district vaccinators made false returns, which are now checked by closer supervision and by punishment; and (*c*) that an indifferent class of men seek employment as vaccinators. The last statement quite falls in with Dr. Pedley's contention. Vaccinators, it seems, have an average pay of about 27 rupees a month and this includes travelling expenses, so that coolies can earn more in the port of Rangoon. The questions raised by Dr. Pedley are certainly serious and demand full investigation. It is the boast of Britain that subject races benefit by its control. Obviously health administration is among the most important functions of central and local government. The Burmese are said to be a reasonable people, ready to accept vaccination if offered to them by trustworthy hands. In such circumstances the proportion actually vaccinated, which is given as about 300 per 10,000 of population in Lower Burma in 1902-03, is miserably small, and Dr. Pedley makes out a strong case for governmental responsibility for this most unsatisfactory state of affairs. The subject is very well worth the attention of those members of the British Parliament who take special interest in the welfare of our great dependencies in the Far East.

ON THE USE OF ALCOHOL IN CASES OF PNEUMONIA.

IN a suggestive and carefully reasoned paper on pneumonia, read before the Liverpool Medical Institution by Dr. John Hay and recorded *in extenso* at p. 1643 of this issue, some strong views are expressed against the routine use of alcohol in cases of threatened cardiac failure during the course of that disease, supported by statistics and tables of somewhat startling character. He found that in considering a group of 150 cases, 47 of which were treated by himself without administration of alcohol, while the remaining 103 were treated by his colleagues, alcohol being given when the usually recognised indications for its administration arose, the mortality in the former group (those untreated by alcohol) was 16 per cent. less than that in the latter, or, eliminating the cases admitted moribund from both groups, there was a difference of 15 per cent. in favour of the cases treated without alcohol. Dr. Hay states that he has taken great care to eliminate every source of error and we must accept his figures as showing the difference he claims. At the same time there would seem to us to be one or two factors requiring elucidation, leaving out of consideration the smaller number of cases dealt with in the former group. First, although the average age of the two groups of cases is practically identical, it would have been of interest to compare the age mortality of the two groups in decade periods. Again, considering the group of 103 cases treated by his colleagues with alcohol there would seem to be three possibilities: first, that all the patients seen by them were treated with alcohol; or secondly, that the cases not treated by alcohol were excluded, which would seem to be negatived by the statement that no selection was made; or thirdly, that this group includes cases to which no alcohol was given, in which case it would be of interest to know what proportion these form of the total. These are points which require elucidation before the absolute value of the figures given can be made out. Dr. Hay quotes the currently received views of the pharmacological actions of alcohol in support of his conclusions—viz, that it dilates the peripheral vessels and lowers the blood pressure, exerting no direct action upon the heart itself except to enfeeble it in large doses. At the same time examples are not wanting of drugs which seem to exert actions in disease almost in defiance, so to speak, of their pharmacological actions. Strychnine itself, which Dr. Hay so rightly commends as "a good stimulating cardiac tonic," is a case in point, for according to many pharmacologists strychnine has no action upon the heart, producing its effects on the vascular system entirely through the vaso-constrictor centre. We hold no brief for the use of alcohol in pneumonia; in fact, there is little doubt that it is frequently administered in too large amounts and too early in the disease. At the same time we cannot but feel that with so large a variation as 15 or 16 per cent. in so relatively small a group of cases the difference may be due to more than the one variant, especially when we remember that some statistics in other diseases—notably typhoid fever—certainly seem in favour of the use of alcohol. Dr. Hay's statistics are, however, a valuable contribution to a debateable question and we may express the hope that his work will direct attention to the matter and stimulate others to make observations.

---

[1] THE LANCET, April 30th, 1904, p. 1221.

THE CORONERS' SOCIETY.

THE Coroners' Society of England and Wales held its annual banquet at the Holborn Restaurant, London, on June 2nd. Amongst those present were the President of the society, Mr. H. White, who took the chair; Mr. Gray Hill, the President of the Law Society; Mr. H. A. Harben, chairman of the Public Control Committee of the London County Council; Mr. C. E. Troup, C.B., Mr. William P. Byrne, C.B., Mr. W. O. Danckwerts, K.C., Mr. William Martin, M.A., LL.D., Mr. M. L. Macnaughten, Assistant Commissioner of Police; the Mayors of Richmond (Surrey), West Ham, and Bury (Lancashire), Mr. T. Fraser Black, J.P., Mr. W. G. Austin, Mr. C. Edgar, J.P., Mr. W. H. Eves, J.P., Dr. G. Danford Thomas, Dr. F. J. Waldo, Mr. M. H. Taylor, Dr. S. I. Oddie, Dr. R. L. Guthrie, Dr. Ernest W. White, Dr. T. Outterson Wood, Mr. S. F. Butcher (vice-president), Mr. Walter Brooke, Mr. F. Danford Thomas, Mr. A. M. M. Forbes, Mr. R. M. Mercer, Mr C. L. Rothera, Mr. T. Christophers, Mr. A. C. Langham, Mr. Luke White, M.P., Mr. Isaac Bradley, Mr. G. E. Hilleary, Mr. Lovell Smeathson, Mr. H. B. Sewell, Mr. E. D. Prickman, Mr. Walter E. Cunliffe, Mr. Henry White, jun., Mr. J. R. Richards, Mr. W. W. Parker, Mr. G. P. Wyatt (honorary treasurer), and Mr. Walter Schröder (honorary secretary). After the usual loyal toasts had been honoured Mr. Butcher proposed the toast of the "Imperial and Local Government," and in the course of his remarks pointed out that the Government should take more heed of the advice obtainable from coroners. Mr. Luke White, in replying, commented on the valuable experience gained by the coroners in connexion with the problem of the housing of the poor. Mr. Harben, who also acknowledged the toast, referred to the connexion between the London County Council and the coroners. The Mayor of Richmond, who also answered to this toast, spoke of the duties devolving on the coroners and men- [illegible]

and especially dwelt on the good work done by Dr. Danford Thomas in supplying important information for the use of the Home Office. The toast of "The Officers of the Society," which was proposed by the President, was cordially received and was acknowledged by Mr. Schroder.

THE DISTRIBUTION OF PLAGUE.

THE medical officer of health of the Cape Colony states that for the week ended May 14th there was only 1 case of plague discovered in the colony—namely, a native male at Port Elizabeth. 395 rats and 127 mice were examined bacteriologically during the week, of which 4 rats proved to be plague infected. In the Cape Town and Harbour Board area 522 rodents were examined during the week but none were affected with plague. With reference to the Transvaal the following motion was passed unanimously by the Transvaal Medical Society at the meeting held in the board room of the Johannesburg Hospital on April 7th:—

> th [illegible]
> or [illegible]
> M [illegible]
> w [illegible]
> co [illegible]
> wl [illegible]
> the disease. In the opinion of this society their promptness and energy have undoubtedly led to the saving of many lives.

As regards the Transvaal, a telegram from Lord Milner, received at the Colonial Office on June 4th, states that the plague return for the week ending that date was as follows: total number of fresh cases reported since May 28th, 2, both coloured persons. 3 cases have been found not to be plague, making present total of suspected and proved cases 139, 24 being whites and 115 coloured persons. The total number of deaths reported since May 28th was 1, a coloured person. As regards the Mauritius, a telegram from the Acting Governor, received at the Colonial Office on June 4th, states that for the week ending June 2nd there were 3 cases of plague and 2 deaths from the disease. In Hong Kong for the week ending June 4th there were 36 cases of plague and 37 deaths from the disease.

ON THE OCCURRENCE OF PENTOSURIA AS A FAMILY ANOMALY.

UNDER the above title Dr. M. Bial[1] of Kissingen records three cases of pentosuria occurring in one family. The first case was that of a married woman from Lodz who was referred to Dr. Bial for some slight degree of glycosuria with obesity. An analysis of the urine in a chemical laboratory at Lodz showed a reduction equivalent to 0·3 per cent. of sugar. Dr. Bial on testing it found that with Fehling's solution it gave a distinct reduction which appeared during boiling, while with the pentose testing reagent described by him[2] a very definite reaction was obtained. No results were obtained with fermentation or polarisation experiments. To confirm the presence of pentose the phenylhydrazin test was applied and the osazone was prepared from one litre of urine, about 0·5 gramme being obtained. This proved to be pentosazone, since its melting point was 150° C. and its nitrogen content was 17·01 per cent., while glucosazone has a melting point [illegible] 6 per cent. The br [illegible] came under observa [illegible] examinations of his [illegible] from 0·1 to 0·3 per cent. Dr. Bial, by the application of the same tests, was able to show that the reduction of Fehling's solution [illegible] patient, who was of neuropathic [illegible] ncies, was assured that his con- [illegible] ne, and not the grave disease he had imagined it to be. Another sister of this patient had also been regarded as diabetic but an examination of the urine proved the sugar to be pentose and not glucose. The urine of several other members of the same family was examined, including that of the father, of two other brothers, and of two children daughters of the first and third patients respectively, but neither glycosuria nor pentosuria was found. The paper contains an interesting *résumé* of the literature of pentosuria. The condition was first described by Salkowski and Blumenthal in 1895,[3] since which time a number of cases have been recorded by different authors, more especially during the last three years, among them in two sisters by Blumenthal. Both Dr. Bial and Dr. Blumenthal regard pentosuria as an anomaly of metabolism comparable to cystinuria, which has also recently been regarded as a family disease by Dr. Abderhalden. The importance of the condition of pentosuria, which is apparently harmless in itself, is its liability to lead to wrong conclusions in life assurance work and to its confusion with glycosuria and diabetes. It would certainly seem to be worth trying Dr. Bial's test in some of the cases in which a small or an anomalous reduction is obtained with Fehling's solution, as is the case in a not inconsiderable number of urines.

[2] THE LANCET, April 19th, 1902, p. 1123.

LEPROSY IN NEW SOUTH WALES.

IN a report to the Colonial Government, dated March 31st, 1904, Dr. J. Ashburton Thompson states that on Jan. 1st, 1902, there were 14 persons (13 men and one woman) remaining under detention in the lazaret at Little Bay, not far from Sydney. One patient was admitted, two died, and three were discharged during the year. There were therefore ten persons remaining in the lazaret at the end of the year; three were natives of New South Wales, of European descent, one was a native of Germany, one was a native of England, one was a native of the United States of America, one was a Javanese, and three were natives of China. The three patients who were discharged suffered from lepra nervorum; one of them returned to his home in the Island of Aoba and two, who were white natives of the colony, returned to their homes on the ground that the disease was quiescent. A charitable allowance was made to the family of one of them as it was very unlikely that his trophic mutilations would allow of his earning a livelihood. The working expenses of the lazaret for the year were £1696, being an average of £133 7*s.* 9*d.* per inmate per annum.

MEDICAL EXCURSIONS TO FRENCH WATERING PLACES.

THE sixth annual excursion to French watering places will commence on Sept. 3rd and will continue till the 15th. As on the previous occasions the leader of the party will be Dr. Landouzy, professor of clinical medicine in the Paris Faculty, who will address meetings at various places on the subject of the therapeutic applications of mineral waters. The district to be visited is in Central France and Auvergne. The party will assemble on the forenoon of Sept 3rd at Lamotte-Beuvron which is a station on the Orleans Railway between Orleans and Vierzon. An express train from Paris arrives about 10 A.M. After lunch and a visit to the sanatorium the party will leave at 3 P.M. for Chamblet-Néris. Among the numerous places subsequently visited will be La Bourboule, Le Mont-Dore, Royat, and Vichy. The party will separate at Pougues-les-Eaux on Sept. 15th. Only medical men and medical students, French or foreign, are eligible to join the excursion; medical men may be accompanied by their wives. All the French railways will convey members from their homes (and in the case of foreign arrivals from the frontier station) to Lamotte-Beuvron and on the corresponding return journey from Pougues at half fares. Intending visitors should communicate with Dr. Carron de la Carrière, 2 Rue Lincoln, Paris (8me), giving their names, addresses, the name of the railway station from which they will start, and, in the case of foreign visitors, the name of the frontier station by which they will arrive. Names cannot be received after August 15th. The subscription of 250 francs (£10), covering all the expenses of the excursion, should be paid to the Director of the Crédit Lyonnais, Agence B, Compte V.E.M., Place de la Bourse, Paris.

RADIO-ACTIVITY IN RUSSIAN MUD BATHS.

AT a meeting of the Physical Section of the Russian Physico-Chemical Society on May 24th Professor I. I. Borgman gave a report on the results of his inquiry on the radio-activity of certain Russian mud baths. The lecturer demonstrated on a screen. He had found that the mud baths of Kuyalnitsk and Arensburg possess radio-activity, whilst those of Berdyank and Saska possess this quality only to a very limited extent. But samples from other baths showed no signs of it. His systematic tests began on March 17th and continued right on till May. Some of the effects observable were that the sulphuric acid that served to dry the mud of the Kuyalnitsk baths as well as the vessels and other objects that had been in contact with it had acquired the radio-active property. Professor Borgman had sent a sample of the mud bath of Kuyalnitsk to Dr. London who tested it for bacteria and found that it arrests the growth of bacteria. It seems probable that radio-emanations are ubiquitous and more than a year ago Professor J. S. Thomson of Cambridge found evidence of them in ordinary drinking wells and in the earth. More recently the same property has been found to reside in the thermal waters of Bath and Buxton, while Droitwich brine is also radio-active. The subject is still steeped in obscurity but it is not improbable that radio-activity may be found to be a factor of considerable importance in hydrotherapeutic practice. It may be concerned in the beneficial effects of a mud application. All muds are not curative, neither is it probable that they are all radio-active or inhibitory to the growth of micro-organisms.

HIS MAJESTY THE KING has graciously consented to lay the foundation-stone of the new buildings of St. Bartholomew's Hospital during the course of next month.

THE Cavendish lecture of the West London Medico-Chirurgical Society will be delivered by Professor von Mikulicz of Breslau on Friday, June 24th, at 8.30 P.M., in the Town Hall, Hammersmith. The subject is, Experiments on the Immunisation of Operation Wounds. A conversazione will follow.

AT the annual meeting of the Incorporated Medical Practitioners' Association, held on June 2nd, Mr. Robert Ambrose, Member of Parliament for the Western Division of County Mayo, was elected president for the ensuing year.

CARDIFF INFIRMARY.—The committee of the Cardiff Infirmary Sunday Fund announces that as a result of the collections on "Infirmary Sunday" (April 24th) the sum of £590 has been handed to the institution. The committee, however, will keep the fund open until Dec. 31st so that any congregation which had not been able to arrange for a collection on April 24th may have an opportunity of doing so.

Looking Back.

FROM

THE LANCET, *SATURDAY*, June 10, 1826.

DR. HOPE AND HIS LECTURE TO THE LADIES OF EDINBURGH.

THE fifteenth day of February of the present year will be long considered a remarkable era in the history of the modern Athens. For the first time, we believe, that any thing of the kind has been attempted in Europe, the splendid portals of the University of Edinburgh were thrown open to the fair sex, and they were permitted to approach the pure fountain of science, and sip a little of its refreshing streams. On that memorable day Dr. HOPE, the Professor of Chemistry, commenced a popular course on that fascinating subject. That learned lecturer has been long celebrated for his oral instruction, but still more famous for his showy experiments exhibited to the grown-up children of the male sex, whose admiration and wonder have been often excited by his Breslaw or Boaz-like dexterity.

Last year his excellent friend and able colleague, Mr. Leslie, condescended to withdraw his attention for a little from his profound speculations on radiant heat, or from the study of the Hebrew language, in which he is so deeply skilled, and astonished the ladies with the wonderful powers of the magic lanthorn and the solar microscope, and while they were glowing with admiration, he cooled their ardour by producing, in a moment, a mountain of ice. Pondering on this extraordinary feat, the learned Professor of Chemistry determined to enter the list of honourable rivalship; and having consulted his honourable patrons, the Lord Provost and Magistrates, on the propriety of this plan, received their unqualified approbation, and announced his intention to the citizens at large. By the way, is this not a direct acknowledgment of the right of the Magistrates of Edinburgh, as patrons of the University, to regulate its affairs, a subject in course of litigation, we understand, in the courts of law, and to which we shall probably soon direct our attention.

The news of the proposed lectures flew on the wings of the wind; and the ladies were delighted to find that they were on the eve of emancipation and were to be entirely relieved from the antiquated shackles, almost indeed corroded with rust, with which they had been long fettered. Dresses, parties, and balls were no longer heard of; the tongue of scandal was silent; chemistry, chemistry and *Hope*, was in every one's mouth, and to be admitted within the walls of the famed University was quite ravishing! The long expected day at last arrived: coaches and chaises, gigs and curricles, were all in requisition. Prince's-street, the fashionable winter promenade of the beaux and belles of the modern Athens, was deserted; the shops of the milliner and silk mercer were abandoned; the voice of the auctioneer was addressed to empty benches, and the strokes of his hammer resounded from the walls of a vacant room. Attracted by the novelty of the exhibition, a dense current of vehicles was seen flowing from North to South before the hour of two o'clock; and as they drew up before the noble portico of the College, and attempted to enter it, what was their surprise and astonishment to find that admission, by the usual approach, was refused; and being ordered to move round to the South side of the edifice, their surprise was not diminished when it was perceived that they must enter the seat of learning by a *window*.[1]

Conversion extraordinary of the Royal College of Physicians at Edinburgh into a Soho-square Bazaar.

THE splendid hall of the Royal College of Physicians in George-street, was opened a few weeks ago, under the auspices of that learned body, as a Bazaar, in which was exhibited an extensive and varied collection of children's frocks, work-baskets, fire screens, caps for dress and undress, child's dolls, pincushions, confectionary, and numerous other articles suited to the taste or agreeable to the palate of an immense crowd of every rank, sex, and age, which the novelty of the scene had attracted to the spot. A brisk sale continued for some hours and we understand that the whole stock was bought up.[1]

[1] Excerpts only have been transcribed.

THE WATERS OF CHÂTEL GUYON.

BY SEYMOUR TAYLOR, M.D. ABERD., F.R.C.P. LOND.,
PHYSICIAN TO THE WEST LONDON HOSPITAL.

IT may interest some of the many readers of THE LANCET to read an account of the above-named health resort and its medicinal waters. I visited Châtel Guyon in the summer of 1902 and I was so much struck with the potentialities of the place that I was prompted to lay before the profession the advantages which sufferers from certain diseases, especially from gastro-intestinal disorders, might derive from a course of the waters there.

Châtel Guyon is comparatively unknown so far as the British public are concerned. Our patients are sent more frequently to Vichy, to Royat, to Mont Dore, to Plombières, or to la Bourboule; whilst Châtel Guyon in the immediate vicinity has been overlooked, notwithstanding that its waters are at least as efficacious as those of its neighbours if not more so. On the other hand, the French and Italians, as well as the people of other nationalities, know the value of its springs and its climate, and patients suffering from certain definite groups of diseases resort there in large numbers for restoration to health. There is even local evidence that the value of its springs was not unknown to the Romans.

The small town of Châtel Guyon is situated in Puy-de-Dôme, Auvergne, at an altitude of about 1500 feet above sea level. The nearest railway station is Riom (on the Paris-Lyon-Méditerranée Railway) about four miles away, whence a good service of omnibuses and carriages conveys visitors through a charming series of vineyards to Châtel Guyon. Riom itself is about eight hours from Paris.

Châtel Guyon consists of two separate portions, an old town and a new town. The former nestles round the side of a high hill quite apart, and its inhabitants are for the most part concerned in agriculture. The new town has sprung up in recent years on the banks of a mountain stream (Sardon) which is largely augmented by the springs which boil up from its bed. In this new town only are found the various springs, baths, and other establishments which require description.

The season extends from May to September inclusive. The best months are July, August, and September. During these months the climate is bland yet invigorating. July is the warmest month but the daily mean variation in temperature only ranges between 55° F. in the early mornings of September and 78° at midday in July. The valley is sheltered from violent winds by vineclad hills, and thunderstorms, though not unknown, are rare and of short duration only. The soil is dry and permeable, there are no stagnant pools as no water collects, and after the heaviest rains the roadways are dry in a few hours.

There are more than 20 springs in Châtel Guyon and many more which could certainly be used with profit are manifest in the bed of the river. Others have doubtless to be discovered. The principal springs or "sources" are named Gubler, Marguerite, Yvonne, and Deval, and although these vary slightly from one another in their physical and chemical qualities I doubt if there is so much difference in their action as to call for special comment. The following characteristics therefore may be regarded as practically common to all.

The water rises up in the basins at a temperature of from 76° to 100°, bubbling and effervescent, with intermittent larger escapes of gas. It is clear, limpid, of slightly acid reaction, odourless, and by no means disagreeable to drink, a slight saline astringent taste being due to iron in solution. It reminds one of draught of flat, warm soda-water. Indeed so palatable is the water that it is freely drunk by the inhabitants in order to quench thirst. The chemical composition of the waters, as will be seen from the following table, shows that they are extremely rich in sodium chloride, magnesium chloride, and also in calcium bicarbonate, with free carbonic acid gas. The quantities are stated according to the metric system of measurement.

	Grammes per litre.
Chloride of sodium	1·6
„ magnesium	1 5
Bicarbonate of calcium	2·1
„ sodium	1·0
„ iron	0·06
„ lithium	0 01
„ potassium	0·2
Sulphate of calcium	0 5
Free carbonic acid gas	1·1
Silica	Trace.
Arsenic	Trace.
Total	8 0

This table shows that the two chlorides which are the most important ingredients are present in the waters to the extent of, roughly, 0·63 grain per ounce. The chloride of magnesium is the most important ingredient and is probably unequalled in quantity by any other known European spring. In fact, it is perhaps the only natural water in which iron, magnesium chloride, and free carbonic acid gas exist together. I know of no other European spring which affords such a large percentage of magnesium chloride, and this property alone should make Châtel Guyon a famous health resort. The temperature of the different springs, however, varies considerably between the 64° of the Source Romaine, which is not much used, and the 95° of the Source Yvonne. The specific gravity of the waters is about 1004 and the quantity issuing from the various springs has been computed at about 500,000 gallons a day, and with this abundant supply it is obvious what a large number of visitors might receive the benefits of the waters, not only internally but in the form of baths. Indeed, the free supply of water fresh from the springs to the bathing establishments is one of the greatest desiderata in the treatment of the various patients who visit this health resort.

The experiments and researches carried out by Sir Lauder Brunton, Laborde, and others show that chlorides, whether of magnesium or of sodium (and the waters of this spa are essentially of this class) increase the activity of the muscular tissue of the empty viscera and of the secretions of the gastro-intestinal canal, as well as of those accessory glands which pour their secretions into it. These salts also exert a direct action on the involuntary muscular tissue, so that the gall bladder and biliary passages contract more vigorously and the more effectually discharge their contents. Hence this effect on the intestinal tube is slightly purgative at the time these waters are being taken, an effect which is not transitory but lasts for a varying time after they have been discontinued. A similar tonic effect on the muscular tissue of the heart is also most noteworthy and is spoken of later.

The waters, as may be inferred, are either (1) drunk, or (2) used for bathing purposes, or (3) used for the irrigation of the stomach, of the larger bowel, or of the vagina, according to the various maladies for which they are prescribed.

1. When taken by the mouth the quantity usually ordered by the local medical man is from half a pint to two pints per diem. When taken in this quantity they are found to restore the muscular tone to the stomach and the intestinal canal and to increase the various secretions which are poured out into this large area and also those of the liver and the pancreas. From the consequent augmented flow of bile and of pancreatic juice the bowels are freely evacuated though never purged and the intestine is in a measure disinfected. Consequently one meets at the various springs patients who have been sent to Châtel Guyon suffering from gout, plethora, habitual constipation, dyspepsia, and atony of the bowels. They include, on the one hand, people who have probably indulged too freely in the pleasures of the table, and, on the other hand, those patients whose sedentary occupations predispose to obesity and whom we send to Carlsbad or to Harrogate. In larger doses (from two to three pints daily) the waters are distinctly purgative. But the effects of these waters are by no means limited to the alimentary system. They produce great changes on the urinary tract. Indeed, from personal experience I am inclined to think that their action on the urinary system is their most marked feature. After a course of the waters not only is the desire to micturate increased but the expulsive power of the bladder is restored, the quantity of urine is greatly increased, its specific gravity is diminished, apparently by cleansing the system of any accumulation or any excess of uric acid and urea, whilst the chlorides are diminished. In addition, I learned from the notes of our medical *confrères* practising in the town that albuminuria is lessened, especially that form which is secondary to diseases of the heart and lungs. These beneficial results would appear to be due principally to the tonic action of the waters on the involuntary muscular system. They have also marked effects on the cardio-vascular system. Not only are the cardiac centres stimulated but the heart muscle itself is strengthened and the systolic thrust is made more vigorous, whilst the pulse-rate is slightly accelerated and its tension is increased. Hence all forms of œdema, and also albuminuria, due to cardiac defects, especially such as are secondary to dilatation of the heart or degenerative changes in its muscular walls, derive extreme benefit from a course of the waters. Indeed, I was so much struck with the potentialities of the springs in this direction that I have suggested to the authorities that they should, under the supervision of the local medical practitioners, train male and female attendants in the methods of administering the graduated exercises which are practised with so much success at Nauheim, Harrogate, and other spas.

2. The baths are also excellent. The original baths situated near the casino are being renovated and replaced by more modern apparatus so as to bring the treatment by balneological therapeutics thoroughly abreast of the times. The bath receptacle itself is of the ordinary shape but of somewhat cold appearance owing to the slight coating of iron oxide which is deposited by the water. Each bath holds about 500 litres or about 100 gallons. The water flows direct from the springs and if necessary its temperature can be raised, but the best effects are probably produced by the water in its virgin state. It flows freely through the bath which is thus practically renewed every four minutes, and hence the bather obtains the full results of the heavy charge of the principal constituents—namely, the chlorides, bicarbonates, and the free carbonic acid gas. On entering the bath the first sensation is rather depressing; this, however, speedily gives way to one of agreeable pleasure as the temperature of the water (33·5° C. = 92·3° F.) is that of a "warm bath." It also affords a peculiar and characteristic oleaginous or velvety sensation to the skin and one feels as though one could easily float on the surface. After reclining a few minutes it is found that innumerable small bubbles of carbonic acid gas have adhered to the surface of the body, and these, increasing in size by amalgamation, finally become detached and rise to the surface. The effect of all this is to produce vaso-motor action. The capillaries are dilated and there is a sense of general warmth. This is more especially noticed on emerging from the bath after 20 minutes' immersion, when the skin is reddened and there is a feeling of warmth and glow. But above all is the agreeable sensation of increased bodily activity and elasticity. A walk which prior to the bath would have seemed to be irksome is now taken with spirit and eagerness, whilst any previous oppression, or tiredness, or dyspnœa due to any exertion entirely disappears. The muscular system, both voluntary and involuntary, is braced up; there is an increased secretion from the kidneys and micturition is performed with vigour. The pulse is also increased in volume and tone.

3. In the higher part of the valley a new establishment has been built where, under the care of skilful and highly trained attendants, massage, rectal irrigation, and lavage of the stomach are administered. In the women's department, which is quite isolated and distinct from the male section, there are skilled masseuses who carry out vaginal or rectal douchings which may have been ordered by the physician. From all accounts that I could gather lavage of the stomach is most efficacious in those cases in which dilatation is secondary to fermentation and other effects of bacteria. The carbon dioxide would appear to exert an antiseptic effect on the mucosa of the stomach, the secretion of the gastric juice is increased in quantity, in acidity, and in activity, whilst the appetite is markedly improved. Chronic cases of atonic dyspepsia appear also to derive extraordinary benefit. Irrigation of the colon is performed in a scientific method which is seldom practised in this country. The water is allowed to pass into the bowel slowly and continuously by force of gravity and measurements are carefully recorded and strictly adhered to according to the physician's directions. If one may judge by the notes readily afforded me by the medical men practising at the spa and also by the large

number of visitors, rectal irrigation would appear to be most useful in those sufferers from corpulence and plethora in whom atony of the lower bowel is a distressing symptom. The local effect of these waters not only increases the natural expulsive power of the rectum but augments the circulation of the bowel generally, and is therefore especially useful in hæmorrhoids an[illegible] On the other hand, patients [illegible] run some risk apparently if th[illegible] lavage at Châtel Guyon. Many cases even during the suppuration stage are sent to Châtel Guyon for cure, a step obviously fraught with danger. Cases even in the subacute stage run some risk and their advent is discouraged by the local physicians. I am not satisfied as to the action of the waters in appendicitis but it is evident that in many instances abscess rapidly forms, calling for urgent surgical treatment. Possibly the strong peristalsis which is set up by the water may stimulate renewed activity in the cæcum and appendix. It cannot be too strongly insisted that cases of appendicitis can only be sent to this spa after most careful consideration when active inflammatory trouble has long since passed away, and even then they should not be sent to Châtel Guyon with the idea of effecting a cure from the use of the waters. On the other hand, patients suffering from that obstinate disorder membranous colitis appear [illegible] from treatment at this resort [illegible] the large intestine which is so [illegible] ere [illegible] of [illegible] of the contents [illegible]

Finally, the hotels are good and there are excellent apartments for those visitors who require privacy.

MEDICINE AND THE LAW.

The Case of Frank Rodgers.

A FEW weeks ago a shocking tragedy in Cambridgeshire attracted considerable attention owing to facts which were indisputable. A boy, 15½ years of age, intentionally shot and killed his mother. She was a drunkard who was intoxicated when he murdered her and he said when he was arrested that he had done it for the sake of his sister. There could therefore be no doubt that the mother's habits and the unhappiness and disgrace in which they involved her family had preyed upon the boy's mind, that he had formed the idea that to take her life would be an effective method of removing her and of thus benefiting his young sister who, as a boy of nearly 16 years of age would no doubt bitterly feel, must suffer from the presence and example of such a mother. He accordingly fired at her with a revolver well knowing what he was doing and having an object in view in doing it. In these circumstances there could be no dispute as to the act being murder or as [illegible] by the prisoner, so that the [illegible] at the recent Cambridge, as[illegible] reference to the state of the poor boy's mind when he aimed the fatal shot. There was nothing in his youth to excuse him and every *person tried for crime is presumed to be of sound mind* until the contrary is proved on his behalf. The evidence elicited on behalf of young Rodgers from the witnesses for the prosecution who were aware of the history of the family was to the effect that the boy was naturally an affectionate son and fond of his mother, that he had grown rapidly and was anæmic, and that he suffered from headaches and bleeding at the nose. It was also proved that his mother's intemperance had caused him acute distress and that her brother and uncle had been addicted to intemperance and had been insane. It was stated later in the case that her father had been intemperate. Medical evidence was given on the prisoner's behalf by Dr. R. Percy Smith and Dr. Charlton Bastian as to the result of their examination of him and as to the extent to which the family history referred to would predispose him towards mental unsoundness. Each of these witnesses admitted, what indeed was plain to all, that the boy knew what he was doing and meant to do it, but Dr. Bastian, in answer to a question put to him in re examination, expressed the view that "the idea that he must put an end to the state of affairs at his home overrode all other considerations and prevented him from being able to tell right from wrong. There was an obsession of the prisoner's mind which warped it like a delusion." In his summing up Mr. Justice [illegible] that "it was suggested [illegible] under an uncontrollable [illegible] which medical men were very fond; but the jury should be on their guard against yielding to it in most cases." The precise meaning of medical men being fond of a particular line of defence is not clear. Medical witnesses give evidence of what they believe to be the fact with regard to a prisoner's condition and it is then for the judge to direct the jury as to whether the condition thus indicated constitutes such insanity in point of law as will entitle the prisoner to be held irresponsible for his crime. The learned judge added, however, that other circumstances proved were in favour of the view that the prisoner did not know the nature and quality of his acts, these being his family history, his physical health, his rapid growth and weakness, his headaches, his bleeding at the nose, and his morbidness and languor shortly before the crime was committed. The jury found that the prisoner was guilty but was insane when he committed the crime, a verdict which was fully justified by the *facts*, and *which might* have been expected to be found in such a case upon less convincing evidence. The reports of the trial do not mention whether any observation was made at any time as to the presence of the revolver in the prisoner's home. Apparently it was borrowed from his brother and a more undesirable possession for a boy than a revolver it is difficult to imagine. In a house where one of the inmates is a drunkard or not of strong mind it is still more dangerous. There is an Act of Parliament which regulates the sale of revolvers but to what extent it is enforced actively throughout the country it is not easy to say. Crimes committed with the cheap pistol are still frequent and prosecutions connected with infringements of the Act, if they occasionally take place, are but rarely reported in the newspapers. And yet the Act provides the police with powers the exercise of which should tend to the prevention of crime, and although far from perfect it is by no means deserving to be neglected. In the absence of a pistol it is quite likely that young Rodgers would never have conceived, or would have been unable to carry out, his insane intention of ridding his family of the mother by depriving her of her life.

ASYLUM REPORTS.

Glasgow Royal Asylum, Gartnavel (Annual Report for 1903).—The average number of patients resident during the year was 441, comprising 184 males and 257 females. The admissions during the year amounted to 154—viz., 71 males and 83 females. Of these 122 were first admissions. Dr. Landel R. Oswald, the medical superintendent, states in his report that the number of the admissions was the largest recorded for some years. All were private patients and 22 sought treatment voluntarily. Alcoholic excess was a prominent factor in the production of the insanity of a large proportion (29) of admissions, but other causes, such as the climacteric and adolescent periods of life, accounted for 17 cases and senile decay for six. A hereditary tendency to insanity or nervous disease was ascertained to be present in the largest proportion of cases (44 in number), "though it probably existed in a larger number though not so admitted by the relatives" of the patients. "I do not wish," continued Dr. Oswald, "to minimise the gravity of the fact that alcoholic excess is year by year being the direct cause of more and more insanity, that organic brain disease is becoming more frequent, and that old age is now, as never before, accompanied by such mental symptoms as to make asylum treatment necessary for the patient's safety; but it is obvious that to solve the problem of the prevention of insanity and the consequent reduction in the number of the insane, we must go further back and eradicate or modify the tendencies that lead to it, whether these are inherited or are acquired in childhood or early life. ...... No one can work amongst those who are the subjects of mental disorder without thinking deeply and often on this subject of the prevention of insanity, and no one can see much of the child life in the poorer parts of a large city without believing that the possibility of the prevention of insanity might be largely brought about by influences brought to bear on them, I believe by their physical and mental education.

...... The education to which I refer must be based on the study of the individual, it must take a large view of the physical as well as of the mental constitution of the child, and it must do so specially when such a child is known to have inherited or acquired a tendency to brain disease." The mental condition of suspected children should be ascertained periodically. The brains of neurotic children are in school life over-stimulated and thereby ultimately weakened. The number of patients discharged as recovered during the year amounted to 53—viz., 23 males and 30 females, or 12 per cent. of the average number resident. The deaths during the year amounted to 30, or 6·8 per cent. as calculated on the same basis. Of the deaths three each were due to senile decay, bronchitis, renal disease, and pulmonary tuberculosis, two to general paralysis of the insane, and the rest to other causes. The Commissioners in Lunacy state in their report that the asylum was in excellent order, that every section of the building had a clean, bright, and well-furnished appearance, that the detached cottages were home-like in their arrangements and afforded most satisfactory accommodation for a selected class of patients, that the patients were evidently managed with consideration and kindliness, that their mental and bodily condition was carefully studied and their individual requirements liberally met, and that the medical registers and case-books were found to be kept regularly and correctly. The committee of management states in its report that "no application for admission even at the lowest rate of board (if the patient was considered a suitable case) was refused during the year. ...... The directors desire it to be known to the medical profession that they are willing, through the physician superintendent, to favourably consider the admission for a limited period, at rates under the lowest fixed amount of £40 per annum, of cases of acute and recent mental illness" of members of the poorer classes.

Derby Borough Asylum (Annual Report for 1903).—The average number of patients resident during the year was 323, comprising 145 males and 178 females. The admissions during the year amounted to 86—viz., 42 males and 44 females. Of these 71 were first admissions. Dr. S. Rutherford Macphail, the medical superintendent, states in his report that "the best test of the increase or decrease of insanity in a district is to take the cases occurring for the first time in each year and to exclude all readmissions. Analysing the admissions from Derby Union for the last three quinquennial periods from this standpoint we find that the average number of first admissions in 1889 to 1893 was 56, in 1894 to 1898 it was 57, while in 1899 to 1903 the average was 69. No doubt there has been a considerable increase of population in recent years and a large and populous area has been added to the borough of Derby in the last quinquennium, but this is not sufficient to account for an increase of over 20 per cent. of the first admissions. We are therefore forced to the conclusion that there is in the borough an appreciable increase of mental disease requiring asylum treatment." The mean age of the patients admitted was 41·5 years and six were over 65 years of age. As usual, nearly two-thirds of the admissions suffered from recognisable physical disease and only six were classified as in average health. Five patients were admitted in a critical and almost moribund condition, two of them dying within a fortnight and the other three in about a month. Hereditary predisposition and alcoholic intemperance were the two chief causes of insanity in the admissions. The number of patients discharged as recovered during the year amounted to 39—viz., 18 males and 21 females or 12·1 per cent. of the average number resident. The deaths during the year amounted to 37 or 11 4 per cent. as calculated on the same basis. Of the deaths two were due to pneumonia, three to pulmonary and other forms of tuberculosis, four to cardiac disease, seven to senile decay, nine to general paralysis of the insane, and the rest to other causes. No serious casualties or accidents have occurred during the year and with the exception of a few cases of influenza there has been no epidemic of infectious disease. The report of the Commissioners in Lunacy is not printed in the present annual report. The committee of management states in its report that the weekly charge of maintenance per patient was 11*s.* 1*d.* for borough patients and 14*s.* per week for out-borough patients. Private patients were charged at the rate of 17*s.* 6*d.* and 21*s.* weekly. The farm accounts showed a profit on the year's working of £252 11*s.* after deducting £147 13*s.* for rent, rates, and insurance.

THE GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

TUESDAY, MAY 31ST.

BUSINESS was resumed on Tuesday, Sir WILLIAM TURNER being in the chair.

Preliminary Scientific Committee.

On the motion of Sir VICTOR HORSLEY, seconded by Dr. MCVAIL, Mr. Jackson was added to the Preliminary Scientific Committee.

Education Committee's Report.

Sir JOHN BATTY TUKE moved the adoption of the report by the Education Committee, which was received and entered on the minutes on Saturday. He said this was the last report he would have the honour of signing as chairman of the committee and he begged to congratulate the Council and the committee on having obtained the services of Dr. Windle who was intimately acquainted with medical education in all its branches.

Dr. WINDLE seconded the motion. He said he could give some additional information as to the ages of the students. He found that the students entered in Birmingham during the last 12 years numbered 552. Of these 26 were under 17 years of age and 526 over. Two were under 16 years of age and of the 26 entered under 17 years of age it was interesting to note that 12 were qualified, 10 were on the way to qualification, whilst the others had given up study. Of the 526 over 17 years of age, 465 were over 18 years of age. The largest number entered at any age was 107 between 17 and 18 years of age and the oldest student was between 41 and 42 years of age. One of the two entered under 16 years of age went out to South Africa as a civil surgeon and wrote to say that he had achieved the ambition of his life in getting a hundred guinea fee for an operation. He was only 25 years of age. As to the section of the report headed "Conference with the Consultative Committee on School-leaving Examinations" he explained that the scheme was now in the hands of the Board of Education, which he hoped would deal with it without very great delay. He could not say anything about the details of the examination. Of course, it would be clear to the Council that the first effect would be to add another to the already long list of examinations, but it was hoped that the final result would be to clear out a great many examinations.

The report was adopted.

Report on Finance.

Dr. PYE-SMITH proposed that the report of the Finance Committee on the Council's income and expenditure for 1903 be received and entered on the minutes. He read the report which was as follows:—

The income of the General and Branch Councils for the year ending Dec. 31st, 1903, was	£8,200 10 7
The expenditure for the same period was	10,365 12 3
Consequently there is a deficit on the year's working of ...	£2,165 1 8

The receipts from fees show an increase of £106 5*s.* 6*d.*, the English Branch having received £143 7*s.* 6*d.* more, the Scottish Branch £99 8*s.* more, and the Irish Branch £136 10*s.* less; the General Council has received £78 less for colonial registrations, and the net increase, therefore, is only £28 5*s.* 6*d.*

It will be remembered that in July last the fees for the registration of additional qualifications and for restoration to the Register were raised from 5*s.* to £1. The result of this is shown in the following table:—

	1902. No. of fees.	1903. No. of fees.	1902. Cash received. £ s.	1903. Cash received. £ s.
English Branch	569	596	142 5	264 5
Scottish Branch	158	152	39 10	112 5
Irish Branch	73	70	18 5	25 15
Total	800	818	£200 0	£402 5

The increased fee has only been in force for five and a half months, but it will be seen that the number of fees received is slightly larger than before, and the net result from the point of view of the Council's finances is certainly satisfactory.

The Irish Branch shows a decrease of 32 in the number of original registration fees received, but the English and Scottish branches show an increase of four and three respectively. The following items of expenditure call for explanation. (*a*) The increase of £181 8*s* in General Council fees is due to the fact that the meetings occupied two days more than in 1902 and the new scale of travelling allowances.

, only came into force gain a special session, Executive Committee

for labour and

of the former index, published in 1887, was £311 17s. for labour and £233 5s. for printing, making a total of £595 2s. (d) The increase of £186 19s. 11d. in the cost of inspection of examinations is due to the larger number of these under review. Owing to the unfortunate illness and death of the inspector the series of inspections was not completed; thus the increase in this item is not so large as it would otherwise have been.

As to the income and expenditure of the three branch councils for the past three years, although no outlay was incurred by the expense of an election (£350), the deficit of the English branch anch shows an re due to the Council. £140 3s. 3d. in

average of the risen £200 since Council received decreased the that is to say,

have been paid will, if sold, add £912 12s. 2d. to the profits.

£1000.

Dr. BENNETT seconded the motion which was agreed to.

On the motion of Dr. PYE-SMITH, seconded by Dr. McCALL ANDERSON, a grant of £150 was made towards the expenses of the Irish Branch Council during the current year.

Election of a Treasurer.

Mr. Tomes was elected one of the two treasurers on the proposal of the PRESIDENT, seconded by Dr. PYE SMITH.

Appointment of Committees.

The following committees were elected:—

The Finance Committee: The Treasurer, Sir Patrick Heron Watson, and Dr. Bennett.

Executive Committee: From the English Branch Council, Dr. Payne, Dr. MacAlister, Dr. Pye-Smith, and Mr. Tomes; from the Scotch Branch Council, Sir John Batty Tuke and Sir Patrick Heron Watson; and from the Irish Branch Council, Sir Charles Ball and Sir C. Nixon. The President is an *ex officio* member.

Penal Cases Committee: From the Irish Branch Council, Sir C. Nixon and Sir W. Thomson; from the Scotch Branch Council, Sir Patrick Heron Watson and Dr. Finlay; and from the English Branch Council, Dr. Windle, Mr. Tomes, Sir Victor Horsley, and Sir Hugh Beevor.

There was a tie in the voting for the Penal Cases Committee between Sir Hugh Beevor and Dr. MacAlister, but Dr. MacAlister retired.

Report of the Public Health Committee.

Dr. BRUCE moved the adoption of the report by the Public Health Committee. The report stated that having considered a communication from the Advisory Board of the War Office the committee had agreed to advise the Council to add to the present list of districts and commands recognised as suitable for the purpose of outdoor training in hygiene under Rule 3 (e) of the Council's resolutions and rules for diplomas in public health the following additional military commands—viz.: Madras, with a civil population of 72,000; Bengal, with a civil population of 38,000; and the Punjab, with a civil population of 42,000. The committee had also considered an application from Dr. Pinching, Director-General of the Sanitary Department of the Ministry of the Interior of Egypt, asking if the Council were prepared to recognise the Sanitary Department of Egypt as competent to issue the necessary certificates to army medical officers and others, required in Rule 3 of the resolutions and rules adopted by the General Medical Council on Dec. 2nd, 1902, and May 29th and Nov. 30th, 1903, for diplomas in public health. The committee recommended that this application should not be granted. The Sanitary Department of the Ministry of the Interior, Egypt, was not under the control of the Director-General of the British Army Medical Department and was in no sense comparable with the districts and commands as defined in Rule 3 (e) of the Council's resolutions and rules for diplomas in public health.

Sir CHARLES BALL seconded the motion which was agreed to.

Report of the Pharmacopœia Committee.

Dr. MACALISTER moved that the report of the Pharmacopœia Committee be received and entered upon the minutes. He read the document as follows:—

hand of the Pharmacopœia is

It will therefore be unnecessary to print a fresh issue this year.

The Executive Committee has referred to the Pharmacopœia Committee for consideration and report a memorial from the Decimal Association and other papers relative to the Weights and Measures (Metric System) Bill, which after amendment by a select committee has passed the House of Lords and is now awaiting consideration by the House of Commons.

The committee have also had before them the notice of motion on the subject which has been placed on the Council's programme by Mr. Jackson.

The committee are strongly impressed with the importance of bringing the weights and measures of the British Pharmacopœia into accord with the international system which is current in the pharmacopœias of all other countries. In the Pharmacopœia of 1898 what may be described as a transitional method was adopted. Doses were expressed in the familiar impe

ceutical processes in

directions for analyti

the metric system to

employed in this c

appreciably simplifie

insert, in reference to dosage at least, equivalents expressed in the old

1651.

Sir JOHN MOORE seconded the motion. He considered that the Council should do everything in its power to facilitate the introduction of the metric system of weights and measures.

The motion was adopted.

The Metric System of Weights and Measures.

Mr. JACKSON moved:—

He said that this country was behind most of the civilised countries in adopting a system of metric weights and measures. The adoption of the metric system would facilitate the teaching of arithmetic in the schools and would save much of the time which could be better devoted to other subjects. This was the testimony of schoolmasters to whom inquiries had been addressed. Such a distinguished man as Lord Kelvin had said in the discussion on the Metric Bill in the House of Lords that the time had come for compulsion in this matter. Some people had said that it would be a long time before the English people would become accustomed to the new system, but he understood that in Germany the people soon got accustomed to it. He did not think that there would be any great danger of confusing "grains" and "grammes" if it were adopted here.

Mr. TICHBORNE seconded the motion. There were two difficulties in connexion with the introduction of the metric system in England. It was the introduction of the international metric system that was proposed, not a metric system based on native measures. The other difficulty was the dose, but he thought that these difficulties would be overcome.

The motion was carried unanimously.

The PRESIDENT: Steps will be taken to communicate this motion to the Lord President.

Report of the Dental Education and Examination Committee.

On the motion of Sir CHARLES BALL, seconded by Dr. LINDSAY STEVEN, the report of the Dental Education and Examination Committee was received and entered in the minutes.

The report contained an allusion to the serious illness of the chairman of the committee, Mr. Tomes, which prevented him from attending it this session.

The first recommendation in the report was:—

> 1. That the application of Mr. Edward Barton Roper for registration as a foreign dentist, under the provisions of Section 10 of the Dentists Act, 1878, be not acceded to.

It was explained in an appendix to the report that Mr. Roper is a dentist of British nationality, but domiciled in France, who has obtained the diploma of Chirurgien Dentiste after three examinations.

Sir CHARLES BALL, in moving that the recommendation of the committee be adopted, said that this case opened up a very large question whether the French curriculum was comparable with those which they had already accepted. There was not sufficient evidence before the committee on that question. It also opened up the legal question of reciprocity. In the absence of Mr. Tomes the committee therefore recommended that the application should not be granted.

Dr. LINDSAY STEVEN seconded the motion and the recommendation was unanimously adopted.

Sir CHARLES BALL moved another recommendation of the committee:—

> That the application of the Dental Board of Victoria for the recognition of the Diploma of Licentiate of Dental Surgery of Victoria be not acceded to.

He said that the committee in examining this application saw that the Dental Board of Victoria fulfilled pretty well the requirements of the Council with one important exception. That exception was that it did not require any evidence that a candidate had been instructed in clinical medicine and surgery. There were lectures on the subject at the dental school, but it was quite clear that a student could obtain its diploma without having seen any other patient but a dental patient. It had been represented to them that this would probably be remedied in future, but in all the circumstances the committee could not recommend the Council to grant the application.

Dr. LINDSAY STEVEN seconded the motion and the recommendation was agreed to.

Dentists and Joint Stock Company Registration.

Sir CHARLES BALL moved:—

> 1. That copies of the judgments in the cases O'Duffy *v.* Jaffe, Surgeon Dentists, Limited, and the Kin[illegible] Joint Stock Companies, together with the [illegible] General Medical Council, be sent to the I[illegible] Council for his information.
>
> 2. That, in view of the judgment of the Chief Baron Palles, the General Medical Council hope that the Government will take such steps as may be necessary: (*a*) To restrain the Registrar of Joint Stock Companies from registering any new company unlawfully using the term dentist or any similar title which would be likely to lead the public to believe that the members of such company were registered dentists when such is not the case. (*b*) To prevent companies already registered from continuing unlawfully to use the term dentist or any similar title which would be likely to lead the public to believe that the members of such companies were registered dentists when such is not the case. (*c*) To in like manner prevent the use by companies of unlawful titles which would be likely to lead the public to believe that the members of such companies were registered medical practitioners when such is not the case.

In submitting this motion Sir Charles Ball said that these decisions had raised questions of great importance to the medical profession as well as to the dental. Under the Dental Act it was held that an unqualified person could not adopt the title of dentist, but in order to obviate this difficulty a number of companies were formed and registered under the Joint Stock Companies Act. The Dentists' Association of Ireland wishing to try a test case of this kind took proceedings against Jaffe and Company, a registered company carrying o[illegible] taken to the King's Bench Division and the decision was that a company not being a person within the meaning of the Act could not be prosecuted for using the title of surgeon dentists. As might be expected this was followed by a large increase of these companies in Ireland. The Board of Trade began to think that this was a serious matter and it suspended the registration of these companies. There was a gentleman named Rowell who felt aggrieved at this action and he therefore applied for a mandamus against the registrar of joint stock companies in Ireland to compel the latter to register his company. The Board of Trade said that it would be bound by any decision which the court arrived at. But even while the case was under discussion the Board of Trade, as he was told, was advised by the law officers of the Crown in Ireland that the decision that a company was not a person within the meaning of the Act was a right decision, and judging by the lists of companies that were being formed the Board of Trade appeared to have resumed the registration of these companies even before the decision in the Rowell case. Sir Charles Ball read a large number of extracts from the decision of Chief Baron Palles in this case in which the latter said: "As the aid of this court and of the prerogative writ of mandamus cannot be granted for the purpose or with the effect of perpetrating a fraud this application ought to be refused and, of course, refused with costs." In conversation with one of the officers of the Crown who took an interest in this matter he distinctly stated that there was not the slightest difficulty in putting an end to all this trouble without legislation if the Board of Trade were to refuse to register any companies in which untrue terms were included. However, there were companies in existence and this was the method which he suggested to stop it. The use of these terms was likely to defraud the public and to make them believe that the companies were registered dentists. When that was not the case they could be enjoined at the suit of the Attorney General to stop making use of these terms. He thought that the Council ought to ask the Government to take this step. This matter affected the medical profession in the same way as it affected dentists and he thought that the Board of Trade should not be allowed to register companies as "medical." The Rowell case, he understood, had not been made the subject of appeal to the House of Lords and therefore the decision did not apply to England and Scotland. He was informed, however, that it would receive consideration in similar cases arising in England and Scotland. If the decision were overridden by the House of Lords then legislation might be necessary.

Mr. TICHBORNE seconded the motion which was unanimously carried.

The Medical Act Amendment Bill.

A communication from the Privy Council as to General Laurie's Bill to amend the Medical Act, 1886, was received and entered upon the minutes.

It was agreed to intimate to the Lord President of the Privy Council that the Council would welcome such a change as would facilitate the application to Canada of the provisions of Part 2 of the Medical Act of 1886.

Canvassing for Medical Clubs.

Dr. LINDSAY STEVEN moved:—

> That it be remitted to the Executive Com[illegible] report to the next session of the Council upon [illegible] as systematic canvassing on behalf of a medic[illegible] scribers to a medical club instituted by himself and involving the employment of a paid collector of the entry money and the subscriptions to the club, which would be looked upon by this Council as constituting the practitioner so acting to have been guilty of infamous conduct in a professional respect.

He said the function of the Council was not only to regulate the education of the profession but also to guide its ethics. If the Council formulated a resolution similar to that which it formulated on medical associations and on unqualified assistants for the guidance of the profession he thought it would be a great advantage.

Mr. BROWN, in seconding the motion, said there were numerous private medical clubs and medical men were very much afraid to send out a collector to collect the fees which must be necessarily collected in many cases from patients who resided at a considerable distance from the surgery. It was not the intention of the Council to suppress the existence of clubs. They had existed beyond the memory of man and they discharged a very useful purpose in society. Although the difficulties were great they ought to face them and form some sort of regulation which should be a guide to medical men in this matter.

Dr. MACALISTER said there was one thing that should make the Council pause before issuing a definition of an offence. In the case of covering and medical aid it was after a long series of particular trials that they summed up their experience and adopted resolutions. If they now formulated a definition of the kind of canvassing which was unprofessional and bad they might very well miss out what might happen in the next case. They had better wait before fixing a hard and fast rule which might be got round by the ingenious.

Dr. LINDSAY STEVEN agreed that it might be better to wait and he withdrew his motion for the present.

Issue of Medical Certificates.

In the absence of Sir Victor Horsley Mr. JACKSON moved:—

> That No. 8 of the minutes of the Executive Committee of May 24th, 1904, be referred again to the committee in consultation with the legal advisers as to the action to be taken in regard to the issue of medical certificates contrary to the provisions of the Medical Acts.

The minute of the committee had reference to a communication from the Medico-Political Committee of the British Medical Association forwarding a communication from the education committee of the borough of Bootle in regard to the giving of a medical certificate by a local chemist and druggist in the case of a girl unable to attend school. The committee resolved that the Medico-Political Committee of the British Medical Association be informed that on the face of it the certificate forwarded to the Council appeared to be invalid under Section 37 of the Medical Act, 1858, and that the Council had no jurisdiction over chemists and druggists who gave invalid certificates.

Dr. BRUCE seconded the motion.

Dr. NORMAN MOORE said it was not in the power of the Council to do anything and the Executive Committee ought to be supported in its decision.

Dr. MACALISTER said that when the committee discussed this matter the legal officers were present. The question was entirely a legal one and no action could be taken without a new Act of Parliament. There was no medical question involved.

Mr. JACKSON remarked that they might bring it under the notice of the Central Board of Education.

Sir PATRICK HERON WATSON thought this was a matter of common law.

On a show of hands the motion was defeated.

County of Durham Medical Union.

The Council considered a communication from the County of Durham Medical Union asking if the Council would consent to receive a deputation from the union to lay before it some of the difficulties experienced by the union in its dealings with medical men who did not behave in a professional manner.

Dr. MACALISTER said the Business Committee had left this matter for the Council to decide. He moved that the President of the County of Durham Medical Union be informed that the Council would be prepared to receive a written communication from that body in respect of the difficulties to which it referred and the Council would then be in a position to decide whether any further conference was necessary. He said that deputations were always difficult and not always satisfactory and it was to the advantage of both bodies that the Union should have the opportunity of putting its case in precise language.

Dr. NORMAN MOORE seconded the motion which was agreed to.

Reappointment of Registrar.

The PRESIDENT moved the reappointment of Mr. H. E. Allen as general registrar. He said they all knew from many years' experience, and perhaps no member better than himself, the admirable qualities of Mr. Allen.

The motion was agreed to.

Length of Speeches.

Dr. PAYNE intimated that next session he would move that in order to economise the time of the Council it is desirable to place a limit on the length of speeches of individual members.

Notice of Complaint against Practitioners.

Sir WILLIAM THOMSON moved that it be remitted to the Executive Committee to consider and to draft an instruction to the Penal Cases Committee to ascertain in each case from the person or persons who have lodged a complaint against a practitioner whether the complainant or complainants have brought under the notice of the practitioner charged their disapproval of his conduct. He said the motion had reference to an incident which had occurred in a case the other day.

Dr. M'VAIL seconded the motion which was unanimously agreed to.

This concluding the public business,

Dr. NORMAN MOORE, in moving a vote of thanks to the President, said they all offered their warmest thanks to him for his conduct in the chair throughout the session.

Sir WILLIAM THOMSON seconded the motion which was agreed to.

The Council conducted some further business *in camerâ* and the proceedings of the session terminated.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

ELECTION OF MEMBERS OF COUNCIL.

ON Thursday, July 7th, the Fellows of the Royal College of Surgeons of England will meet to elect three Fellows to fill the vacancies in the Council occasioned by the retirement in rotation of Mr. Thomas Bryant, the resignation of Mr. T. Pickering Pick, and the death of Mr. T. R. Jessop.

The following list of the members of Council gives the date at which each member will retire. The date of the first election is given in every case in which the member has been elected to the Council more than once.

Retire in 1911: Mr. H. T. Butlin, St. Bartholomew's Hospital (first elected 1895); Mr. G. H. Makins, St. Thomas's Hospital; and Mr. C. T. Dent, St. George's Hospital.

Retire in 1910: Professor Howard Marsh, St. Bartholomew's Hospital (first elected 1892); Mr. J. H. Morgan, Charing Cross Hospital; and Mr. H. H. Clutton, St. Thomas's Hospital.

Retire in 1909: Mr. A. W. Mayo Robson, Leeds Infirmary (first elected 1893); Mr. W. Watson Cheyne, King's College Hospital; and Mr. R. Clement Lucas, Guy's Hospital.

Retire in 1908: Sir Alfred Cooper (first elected 1892); Dr. J. Ward Cousins, Royal Portsmouth Hospital (first elected 1895); and Mr. A. Pearce Gould, Middlesex Hospital.

Retire in 1907: Mr. H. W. Page, St. Mary's Hospital; and Mr. C. W. Mansell Moullin, London Hospital.

Retire in 1906: Mr. F. Richardson Cross, Bristol Royal Infirmary; Mr. Henry Morris, Middlesex Hospital (first elected 1893); and Mr. John Langton, St. Bartholomew's Hospital (first elected 1890).

Retire in 1905: Mr. J. Tweedy, President, University College Hospital (first elected 1892); Sir Henry G. Howse, Guy's Hospital (first elected 1889); Mr. Edmund Owen, St. Mary's Hospital; and Mr. Rickman J. Godlee, University College Hospital.

Retires in 1904: Mr. Thomas Bryant, Guy's Hospital (first elected 1888).

We understand that at present there are seven Fellows who are candidates for the three vacant posts of the Council; they are in alphabetical order: Mr. H. Gilbert Barling of Birmingham, Mr. C. H. Golding-Bird of Guy's Hospital, Mr. A. A. Bowlby, of St. Bartholomew's Hospital, Mr. W. Bruce Clarke of St. Bartholomew's Hospital, Mr. Harrison Cripps of St. Bartholomew's Hospital, Mr. Frederic S. Eve of the London Hospital, and Mr. J. Bland-Sutton of the Middlesex Hospital. It is possible that there may be more candidates, for nominations can be received up to Monday next, June 13th. Nomination forms can be obtained from the secretary.

REVIVAL OF THE FELLOWS' DINNER.

It is intended to hold a Fellows' dinner on the evening of the day of election to the Council and it is hoped that it will serve as an occasion for the meeting of the Fellows, for since the introduction of voting by post for the Council the personal attendance of Fellows has greatly diminished.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In 76 of the largest English towns 9279 births and 4277 deaths were registered during the week ending June 4th. The annual rate of mortality in these towns, which had been 16·1, 15·5, and 15·4 per 1000 in the three preceding weeks, further declined last week to 14·6 per 1000. In London the death-rate was 13·2 per 1000, while it averaged 15·2 per 1000 in the 75 other large towns. The lowest death-rates in these towns were 5·5 in King's Norton, 7·0 in Handsworth (Staffs.), 8·0 in Burton-on-Trent, 8·7 in Newport (Mon.), 9·0 in West Hartlepool, 9·4 in East Ham, 9·5 in Smethwick, 9·6 in Hornsey, and 9·9 in Coventry; while the highest rates were 18·8 in Stockport, 18·9 in Middlesbrough, 20·3 in Norwich, 21·3 in Preston, 22·2 in Newcastle-on-Tyne, 22·5 in Huddersfield, 24·0 in Warrington, and 34·9 in Wigan. The 4277 deaths in these towns last week included 495 which were referred to the principal infectious diseases, against 525, 528, and 519 in the three preceding weeks; of these 495 deaths 217 resulted from measles, 125 from whooping-cough, 58 from diarrhœa, 40 from diphtheria, 30 from scarlet fever, 23 from "fever" (principally enteric), and two from small-pox. No death from any of these diseases was registered last week in Willesden, Hornsey, Hastings, Plymouth, Devonport, Burton-on-Trent, Walsall, West Bromwich, Grimsby, Barrow-in-Furness, Rotherham, Tynemouth, or Newport (Mon.); while among the other towns the highest death-rates from the principal infectious diseases were recorded in Walthamstow, Hanley, Warrington, Salford, Burnley, Huddersfield, Leeds, Sunderland, and Rhondda. The greatest proportional mortality from measles occurred in Walthamstow, Norwich, Birkenhead, St. Helen's, Burnley. Huddersfield, Leeds, Newcastle-on-Tyne, and Rhondda; from scarlet fever in Hanley and Warrington; from diphtheria in Hanley and Stockton-on-Tees; from whooping-cough in Birmingham, Smethwick, Warrington, Bolton, Blackburn, and Swansea; and from "fever" in Wigan. Of the two fatal cases of small-pox registered in these towns last week one belonged to Leicester and one to Halifax. The number of small-pox patients under treatment in the Metropolitan Asylums hospitals, which had been 99, 96, and 118 at the end of the three preceding weeks, had declined again to 96 at the end of last week; 10 new cases were admitted during the week, against 26, 18, and 33 in the three preceding weeks. The number of scarlet fever cases in these hospitals and in the London Fever Hospital on Saturday last, June 4th, was 1673, against 1600, 1630, and 1663 on the three preceding Saturdays; 207 new cases were admitted during the week, against 239, 222, and 194 in the three preceding weeks. The deaths in London referred to pneumonia and to diseases of the respiratory system, which had been 231, 210, and 188 in the three preceding weeks, further declined to 181 last week but were nine in excess of the number in the corresponding period of last year. The causes of 50, or 1·2 per cent., of the deaths in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Leicester, Bolton, Salford, Leeds, Newcastle-on Tyne, Cardiff, and in 46 other smaller towns, while the highest proportions of uncertified deaths were registered in Birmingham, St. Helen's, Preston, Sheffield, Hull, Sunderland, Gateshead, and Tynemouth.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 17·9, 18·7, and 17·6 per 1000 in the three preceding weeks, rose again to 18·1 per 1000 during the week ending June 4th and was 3·5 per 1000 in excess of the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 10·8 in Perth and 13·0 in Leith to 19·4 in Greenock and 23 0 in Dundee. The 600 deaths in these towns included 26 which were referred to whooping-cough, 16 to measles, 14 to diarrhœa, three to scarlet fever, three to diphtheria, and two to small-pox, but not any to "fever." In all, 64 deaths resulted from these principal infectious diseases last week, against 75, 58, and 62 in the three preceding weeks. These 64 deaths were equal to an annual rate of 1·9 per 1000, which was 0·2 per 1000 above the mean rate last week from the same diseases in the 76 large English towns. The fatal cases of whooping-cough, which had been 28, 21, and 29 in the three preceding weeks, declined again last week to 26, of which 16 occurred in Glasgow, four in Edinburgh, three in Aberdeen, and two in Paisley. The deaths from measles, which had been 17, 16, and 12 in the three preceding weeks, rose again to 16 last week, and included six in Greenock, four in Edinburgh, three in Glasgow, and three in Dundee. The fatal cases of diarrhœa, which had been 13 and 15 in the two preceding weeks, decreased last week to 14, of which seven were registered in Glasgow, two in Edinburgh, two in Dundee, and two in Aberdeen. The deaths from scarlet fever, which had been four, four, and two in the three preceding weeks, rose again to three last week, and included two in Edinburgh, where two of the three fatal cases of diphtheria also were registered. The two deaths from small-pox belonged to Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 90, 97, and 85 in the three preceding weeks, rose again last week to 87, but were 24 below the number in the corresponding period of last year. The causes of 34, or nearly 6 per cent., of the deaths registered in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 21·6, 21·9, and 21·3 per 1000 in the three preceding weeks, further declined to 19·7 per 1000 during the week ending June 4th. During the past four weeks the death-rate has averaged 21·1 per 1000, the rates during the same period being 14·7 in London and 18·2 in Edinburgh. The 143 deaths of persons belonging to Dublin registered during the week under notice showed a decline of 12 from the number in the preceding week and included 16 which were referred to the principal infectious diseases, against 17, 13, and 8 in the three preceding weeks; of these, 9 resulted from whooping-cough, five from measles, and two from "fever," but none from small-pox, scarlet fever, diphtheria, or diarrhœa. These 16 deaths were equal to an annual rate of 2·2 per 1000, the death-rates last week from the principal infectious diseases being 1·6 in London and 2·2 in Edinburgh. The fatal cases of whooping-cough, which had been ten, five, and four in the three preceding weeks, rose again last week to nine. Five deaths from measles were recorded last week, against two, two, and none in the three preceding weeks. The 143 deaths in Dublin last week included 21 of children under one year of age and 39 of persons aged 60 years and upwards; the deaths of infants showed a slight decline, while those of elderly persons exceeded the number in the preceding week. Two inquest cases and two deaths from violence were registered, and 55, or more than a third, of the deaths occurred in public institutions. The cause of only one death registered in Dublin last week was not certified.

THE SERVICES.

Royal Navy Medical Service.

Appointment of Director-General.

Inspector-General Herbert Mackay Ellis has been selected for the appointment of Director-General of the Medical Department of the Royal Navy, in succession to Inspector-General Sir Henry Frederick Norbury, K.C.B., who will shortly relinquish that post.

Royal Army Medical Corps.

Lieutenant-Colonel C. Seymour, has been selected to succeed Colonel T. Ligertwood as physician and surgeon of the Royal Hospital, Chelsea, and has taken up the duties there.

Indian Medical Service.

Colonel W. R. Browne has been selected to officiate as Surgeon-General with the Government of Madras, in the absence of Surgeon-General D. Sinclair, on leave in England.

Army Medical Reserve of Officers.

Captain F. D. Woolley, Royal Army Medical Corps Volunteers, to be Surgeon-Captain (dated June 4th, 1904). Surgeon-Lieutenant J. R. Williams, 3rd Volunteer Battalion the Royal Welsh Fusiliers, to be Surgeon-Lieutenant (dated June 4th, 1904).

IMPERIAL YEOMANRY.

Northumberland (Hussars): Surgeon-Captain A. Brumell to be Surgeon-Major (dated June 4th, 1904). Oxfordshire (Queen's Own Oxfordshire Hussars): Surgeon-Lieutenant (Honorary [illegible] resigns his [illegible] (Queen's Ov[illegible] McCall resigns his commission (dated May 28th, 1904).

VOLUNTEER CORPS.

Royal Garrison Artillery (Volunteers): 1st Carnarvonshire: The undermentioned officers are transferred from the 1st Cheshire and Carnarvonshire Royal Garrison Artillery (Volunteers);—To be Lieutenants: Surgeon-Lieutenant-Colonel E. J. Lloyd (dated June 4th, 1904) and Surgeon-Lieutenant C. W. Owen (dated June 4th, 1904).

Rifle: 1st Volunteer Battalion the Manchester Regiment: Surgeon-Captain W. F. O'Grady to be Surgeon-Major (dated June 4th, 1904). 5th (Ardwick) Volunteer Battalion, the Manchester Regiment: Surgeon-Major J. G. Saville resigns his commission and is granted the honorary rank of Surgeon-Lieutenant-Colonel, with permission to wear the prescribed uniform (dated June 4th, 1904). 5th (Irish) Volunteer Battalion, the King's (Liverpool Regiment): Surgeon-Lieutenant-Colonel D. E. Flinn resigns his commission and is granted the honorary rank of Surgeon-Colonel, with permission to wear the prescribed uniform (dated May 28th, 1904); Surgeon-Lieutenant J. G. Moyles resigns his commission (dated May 28th, 1904); Lieutenant H. M. Bayer resigns his commission and is appointed Surgeon-Lieutenant [illegible] John Mauries Ahern to be Sur[illegible] 28th, 1904). 3rd Lanarkshire: [illegible] A. Napier to be Brigade-Sur[illegible] [illegible]d is borne as Supernumerary whilst holding the appointment of Senior Medical Officer of the Scottish Rifle Volunteer Infantry Brigade (dated May 28th, 1904). 1st Volunteer Battalion, the Northampt[illegible] H. S. Baker to be [illegible] 2nd (South) Middl[illegible] Isaacs is permitted to change his name to Edmund Percival Isaacs Coke. 4th Volunteer Battalion, the Manchester Regiment: Captain and Honorary Major John Crawhall Nichol, retired, to be Surgeon-Lieutenant (dated May 28th, 1904). 5th (Glasgow Highland) Volunteer Battalion, the Highland Light Infantry: Supernumerary Brigade-Surgeon-Lieutenant-Colonel D. Cowie, Senior Medical Officer, Highland Light Infantry, Volunteer Infantry Brigade, resigns his commission, and is granted the honorary rank of Surgeon-Colonel, with permission to wear the prescribed uniform (dated May 28th, 1904).

BEARER COMPANY ROYAL ARMY MEDICAL CORPS (VOLUNTEERS).

3rd London Bearer Company: Captain E. Lloyd-Williams to be Major (dated June 4th, 1904). The London Companies: Captain J. Harper to be Major (dated May 28th, 1904). Gloucester and Somerset Bearer Company: David Brynmor Chiles-Evans to be Lieutenant (dated May 28th, 1904). North-East Lancashire Bearer Company: Captain J. M. H. Martin to be Major (dated May 28th, 1904). 4th or City of London Bearer Company: John Forbes to be Lieutenant (dated May 28th, 1904). Welsh Bearer Company: Major C. Downing to be Brigade-Surgeon-Lieutenant-Colonel whilst holding the appointment of Senior Medical Officer to the Welsh Volunteer Infantry Brigade (dated Jan. 23rd, 1904).

A GALLANT ACTION.

The *London Gazette* of June 7th contains the following: "The King has been graciously pleased to signify his intention to confer the decoration of the Victoria Cross on the under-mentioned officer, whose claims have been submitted for His Majesty's approval, for conspicuous bravery in Somaliland, as stated against his name:—Lieutenant Clement Leslie Smith, Duke of Cornwall's Light Infantry—At the commencement of the fight at Jidballi on Jan. 10th, 1904, the enemy made a very sudden and determined rush on the 5th Somali Mounted Infantry from under cover of bushes close at hand. They were supported by rifle fire, advanced very rapidly and got right amongst our men. Lieutenant Smith, Somali Mounted Infantry, and Lieutenant J. R. Welland, M.D., Royal Army Medical Corps, went out to the aid of Hospital Assistant Rahamat Ali who was wounded and endeavoured to bring him out of action on a horse, but the rapidity of the enemy's advance rendered this impossible and the hospital assistant was killed. Lieutenant Smith then did all that any man could do to bring out Dr. Welland, helping him to mount a horse and, when that was shot, a mule. This also was hit and Dr. Welland was speared by the enemy. Lieutenant Smith stood by Dr. Welland to the end and when that officer was killed was within a very few paces of him, endeavouring to keep off the enemy with his revolver. At that time the dervishes appeared to be all round him and it was marvellous that he escaped with his life."

WAR MEDALS FOR CIVIL SURGEONS.

The War Office announces that a number of war medals for civil surgeons who served with troops during the campaign in South Africa have been received but cannot be forwarded as the present addresses of the gentlemen to whom they have been awarded are unknown. Civil surgeons who have not received their medals are requested to make application to the secretary, War Office, 68, Victoria-street, London, S.W.

THE WAR IN THE FAR EAST.

There are, as is always the case and may be confidently expected, rumours as to military movements that have already been made or are about to take place, but there is little really known about the actual situation of the belligerent forces at the present time and still less of the intentions of those in command of them. We do not, for example, know for certain that General Kuropatkin is moving south in order to relieve the garrison in Port Arthur in deference to the pressure of political opinion in Russia, nor does it seem likely that the Czar should have issued any definite order in favour either of the alleged policy of Admiral Alexeiff or that of General Kuropatkin. But there does not seem to be any doubt about the Japanese intentions to attempt the capture of Port Arthur, for which they have been carefully preparing. From a strategical and military point of view the situation is most interesting when it is remembered that in addition to the large Japanese force besieging Port Arthur there are the two other Japanese armies in the field under Generals Kuroki and Nodzu watching the Russian movements and presumably ready to strike in at an opportune time on the Russian flank and rear. But so far as the medical aspects of the campaign are concerned there is a comparative dearth of information. It is understood that hospital accommodation and preparations on a large scale have been provided at Vladivostock of which place, however, we hear almost nothing.

A Russian medical man who has lived a long time in Japan writes in the *Warsaw Dnevnik* on the hospitals of the Japanese Red Cross Society as follows. The wards, corridors, and specialists' cabinets are wonderfully clean and neat, and the cabinets are furnished with all necessary instruments and appliances. Every 40 or 50 steps along the main passages short light corridors branch off, each ending in an invalids' room. All the bedsteads are iron, they are very wide, and are provided with excellent linen. The wards in the chief hospital of the society, as indeed in all Japanese hospitals, are divided into four classes: those of the first class accommodate only one patient, or at most two; those of the fourth class will take in as many as 20 or 24 patients in one large room. But everywhere uniform cleanliness and order prevail. No smell is allowed to hang about. Ventilation is assured. The illumination is by electricity and the heating by stoves. He closes his article by observing that such knowledge makes it more comforting to the relatives of such as may fall into their hands, for their conduct towards their invalided enemies is "correct."

JOURNAL OF THE ROYAL ARMY MEDICAL CORPS.

The June issue of the *Journal of the Royal Army Medical Corps* contains a communication by Mr. Ernest E Austen of the Zoological Department of the British Museum on the House Fly and certain Allied Species as Disseminators of Enteric Fever among Troops in the Field. The author quotes many facts to prove his thesis and after discussing the natural history of the order diptera rightly says: "It is one thing to draw attention to admitted facts and quite another to indicate a remedy." He hopes, however, that the authorities of the Royal Army Medical Corps will without delay seriously consider the question of flies and latrines in standing camps in hot climates. "Unless this be done and material improvements in the existing system be effected it is inevitable that recent experience will be repeated in the next great war in which we are involved and wastage from enteric fever will continue to the same extent as of old." The paper is a suggestive one and deserves careful attention. Among the other communications we may call attention to Mauser Bullet Wounds of Nerves, a Surprising Lesion, by Major S. F. Freyer, C.M.G., R.A.M.C.; Major J. Fayrer's contribution on High-frequency Currents; Lieutenant-Colonel A. M. Davies's notes on the Instruction of Staff and Regimental Officers in Military Hygiene; and the second part of the editorial article on Malta Fever.

Permission has been given to Dr. Fristedt, assistant surgeon, Swedish Army, to visit the barracks and hospitals in London about the beginning of August.

A walking contest between soldiers which took place in the outskirts of Paris on May 29th has resulted in one death and numerous cases of heat-stroke. 30 per cent. of the competitors are said to have been in need of medical assistance. The distance was about 28 miles.

It has been decided to abolish the rum ration on transports and to substitute, on homeward voyages only, an issue, on payment of *2d.* a pint, of British-brewed ale or an alternative ration of chocolate at *½d.* a pint, to troops who desire to make such purchases.

Correspondence.

"Audi alteram partem."

HOSPITAL SUNDAY.

To the Editors of THE LANCET.

SIRS,—I am this year President and Treasurer of the Hospital Sunday Fund and as such I appeal most earnestly to all classes, rich and poor, to assist me, each according to his means, to make the collection as large as possible, for the institutions for which I am pleading are sorely in need of help. All must know of the very great benefits conferred by our hospitals, for not only do they succour the very poor, but as training schools for our medical men they render incalculable services to those who can afford to pay for the skill and experience gained within their walls. Now if everyone will give something to swell the amount I am sure the institutions will be placed in a position to fulfil the charitable duties for which they were established. Mr. George Herring has again with splendid liberality offered to add one quarter, up to £25,000, to the sum collected in places of worship. I am, very truly yours,

J. T. RITCHIE,
Lord Mayor.

Mansion House, E.C., June 6th, 1904.

SPONGES AND FORCEPS LEFT IN THE ABDOMINAL CAVITY.

To the Editors of THE LANCET.

SIRS,—The distressing calamities which occur in connexion with this subject from time to time necessitate, in my judgment, some definite action on the part of surgeons to render this accident impossible. I am thankful to say that one of these surgical disasters has never occurred to myself though operating on all sorts of abdominal cases over a series of years. I have always adhered to two principles: the first to use few sponges and forceps and to have the number of these written on a slate; and the second to verify the sponges and forceps personally after each abdominal case and never to leave this duty to a subordinate. Also I have made it a rule never to pass a sponge deeply into the abdomen without attaching it to a long pair of forceps which projects from the wound and cannot fail to attract attention to the sponge beneath. As for tearing sponges into pieces, or using "wholesale" wool and gauze "dabs," as is often now done, I can only say that such practice is fraught with risk and I cannot too strongly inveigh against it.

On talking this serious matter over with my friend Dr. Hewitt, who from the coign of vantage occupied by the anæsthetist is able to judge largely of surgical practice, he suggested a method for the custody of sponges which I at once put into use. A coarse wire tray is made containing (for myself) six compartments. This lies in the antiseptic lotion and the six sponges are each in its own compartment. At the end of the operation the tray is shown to me with each sponge in its place. The number of compartments may be made to vary with the fancy of the operator as to the number of sponges to be employed. Next as to pressure forceps, I am having constructed a white delf disc 12 inches in diameter and about half an inch thick. In this are bored 18 holes equidistant round the edge. These holes are plainly numbered in red figures. The "clips" stand in the disc and at the end of the operation, before the wound is closed, the operator is shown each pressure forceps in its proper place. He can see that "all is right" at a glance. Added to these precautions the numbers should be written on a slate previously to operation which prevents the error of adding to the number of forceps or sponges after the operation is commenced. Large forceps and clamps can hardly be left in the abdominal cavity. I recommend these simple devices very strongly and earnestly to the notice of my professional brethren both for hospital and private practice. The surgeon cannot avoid personal responsibility for these serious mishaps, and all of us who have been long in practice know of instances of their occurrence in the practice of well-known operators. Such cases have never obtained unfortunate publicity but speak eloquently to the truth of the maxim "Humanum est errare." I am, Sirs, yours faithfully,

A. MARMADUKE SHEILD.

Cavendish-place, W., June 6th, 1904.

THE SO-CALLED PANCREATIC REACTION IN THE URINE.

To the Editors of THE LANCET.

SIRS,—We consider Dr. P. J. Cammidge's reply to our criticism of his "pancreatic reaction" as very unsatisfactory. It will, perhaps, be best to state some of our objections to his "reaction" and to his letter in tabular form so that he and others may the more easily estimate their merits or demerits.

1. Dr. Cammidge's remarks about the varying solubility of lead chloride in hot and cold water were well known to us but as an answer to our criticism are quite beside the mark. The fact that lead chloride is soluble at all in water at 0° C. should have suggested to Dr. Cammidge the necessity of removing the lead salts from the solution with which he was experimenting before proceeding with his test. Therefore we, in estimating the value to be attached to this "pancreatic reaction," thought it advisable to remove this possible source of fallacy and after having done so we found that those cases, pancreatic and otherwise, which previous to the removal of the lead salts gave a positive reaction, now uniformly yielded negative results. These cases included: (*a*) one case of acute pancreatitis; and (*b*) five cases of "chronic pancreatitis"—that is to say, cases in which the pancreas showed distinct evidence of interstitial overgrowth. All these cases were verified post mortem. Surely were the test dependent on any change in the original constituents of the urine, resulting from disease of the pancreas, removal of the lead salts should in nowise interfere with positive results in such cases. How, then, explain the total absence in the above six verified cases of such results?

2. Moreover, the crystals we obtained were not those of lead chloride, as Dr. Cammidge suggests. They were *only obtained* when *phenylhydrazine* hydrochlorate and sodium acetate in solution were boiled with a solution containing lead salts (e.g., as in "Reaction A"). Presumably they consist of a *compound* that the lead salts form with phenylhydrazine. As we stated, they do not appear when the lead salts (chlorides, &c.) are removed previous to adding the phenylhydrazine, &c.

3. The shape of these crystals is almost identical with those of phenylglucosazone, so much so that when both the lead-compound crystals and the latter were present together (as in applying "Reaction A" to unfermented diabetic urine), the two sets of crystals could *not* be distinguished, though each could, by the appropriate processes, be obtained separately and so be compared with those in the mixture. Again, in spite of his assertion that the lead-compound crystals were "quite *distinct* both in behaviour and appearance" from the crystals of his pancreatic reaction we may mention that we have shown them

to competent observers who have been unable to distinguish them from those of phenylglucosazone as examined microscopically. *Since Dr. Cammidge's crystals, according to his* original statement, also resembled very closely those of phenylglucosazone we presume that the lead-compound crystals and his crystals (if these latter have a separate existence) would also closely resemble each other, so much so as to be indistinguishable. Hence his fallacy in neglecting to remove the lead salts must be considered a fatal objection to the value of the reaction.

4. We would like an expression of opinion as to whether Dr. Cammidge gives sufficient grounds for diagnosing so many cases as ones of pancreatic disease. We notice that only three of the cases could be subjected to a post mortem examination, which in most instances is the only true criterion for the presence of disease in the pancreas. We are, of course, aware that acute pancreatitis can usually be correctly diagnosed on the operating table, but we have grave doubts as to whether more chronic and less obvious changes can be unhesitatingly recognised there even by the most skilful hands. How often in the post-mortem room does it require careful handling and close investigation to decide upon these points, which have often to be left to the final arbitrament of the microscope. Does Dr. Cammidge, then, give the profession sufficient proof that the cases he describes as those of pancreatic disease were really of that nature?—We are, Sirs, yours faithfully,

CHARLES E. HAM, M.B Lond.
J. BURTON CLELAND, M D. Sydney.

The Pathological Institute, London Hospital, May 20th, 1904.

To the Editors of THE LANCET.

SIRS,—The correspondence now taking place under the above heading calls to my mind the case of a patient who came under my notice in the South Devon and East Cornwall Hospital, Plymouth. The case was that of a man, aged 50 years, who was admitted under the care of Mr. W. L Woollcombe on March 9th, 1904. His illness had begun in January, 1902, with "wind and distension" together with the passage of loose light-coloured stools. In January, 1903, a severe attack of jaundice occurred and from that date to the time of his admission he was more or less jaundiced with one acute attack in November, 1903, the abdomen remaining distended. On admission to the South Devon and East Cornwall Hospital he was jaundiced, the liver was enlarged, the stools were loose and yellow, and the abdomen was distended. On March 17th the spleen was noticed to be enlarged. No cardiac murmurs were heard.

On March 15th I was asked to examine the blood. There were 4,800,000 erythrocytes per cubic millimetre, 8314 leucocytes per cubic millimetre, 75 per cent. of hæmoglobin, a blood index of 0·7, and films showed the usual proportion of one variety of leucocyte to others. On April 7th I was asked to examine the urine by the "pancreatic" test for chronic pancreatitis.[1] The urine was dark brown in colour and neutral in reaction; its specific gravity was 1015. A cloud of mucus was present. There was no sugar or albumin present. The centrifuged urine contained no calcium oxalate crystals. Gmelin's test for bile pigments and Pettenkofer's for bile salts both gave positive results and the urobilin spectrum was present. The final interpretation of the test in this case, according to Dr. P. J. Cammidge, was either disease other than pancreatic or damage due to past pancreatitis. Indications apart from the conditions of the pancreas existed for operation and cholecystotomy was performed on May 2nd by Mr. Woollcombe but the patient died during the night.

At the post-mortem examination I found great enlarge- [illegible]

The pancreas weighed with adherent tissue about eight ounces and was hard. The spleen weighed two and a half pounds; there were congestion, fibrosis, and perisplenitis. The kidneys were enlarged; the right weighed eight and a half ounces and the left nine ounces; both were congested. The common hepatic, the cystic, the common bile, and Wirsung's ducts were not obviously dilated. The ampulla of Vater was normal and Wirsung's duct opened separately into it. The gall-bladder was contracted and pulled backwards and upwards by adhesions and contained infected bile. There were early peritonitis present and *inflamed lymphatic glands at the portal fissure.* The mitral valve of the heart was thickened and incompetent. The tissues were generally bile-stained. The pancreas showed much interlobular fibrosis, with slight [illegible]. The [illegible] ormal. [illegible] change in the Malpighian bodies. The lymphatic glands contained micro-organisms. Interlobular fibrosis of the pancreas was present, therefore, with slight signs of recent inflammation. The test, repeated carefully on April 14th, was negative as to the presence of chronic pancreatitis, as stated previously. Presumably the stage of the inflammatory reaction determines the result of the test. Perhaps Dr. Cammidge would give his valuable experience (*a*) on this point; (*b*) on the significance, if any, of the smaller number and size of the yellow crystals obtained by method "B" relatively to method "A"; and (*c*) the nature of certain short yellow acicular crystals occasionally formed in the phenylhydrazin test in the urine in the absence of copper-reducing substances. I am indebted to Mr. Woollicombe for permission to publish the case and to Dr. Weatherhead and Dr. Day, house surgeons, for the notes.

I am, Sirs, yours faithfully,
F. G. BUSHNELL, M.D. Lond.,
Pathologist, South Devon and East Cornwall Hospital, Plymouth.

June 4th, 1904.

"EUGENICS."

To the Editors of THE LANCET.

SIRS,—I think it would be impossible to imagine a subject of greater importance to the community than the one Mr. Galton has brought forward. It would be difficult to name one of which the public is more ignorant. The procedure which he suggests to us is admirable. At the root of every moral and social question lies the problem of heredity. Until a knowledge of the laws of heredity is more widely diffused the public will grope in the dark in its endeavours to solve many pressing difficulties. I venture to offer a few remarks on one or two of the questions raised in Mr. Galton's paper.

How shall we bring about a "wide dessemination of a knowledge of the laws of heredity so far as they are surely known and the promotion of their further study"? The study of heredity requires a good deal of knowledge of a rather abstruse kind; above all it requires very close and exact methods of thought. We shall find neither the necessary knowledge nor the exact methods of thought in the average man of business or pleasure who has been trained in the average British home or the average British school. We shall not be able to reach the public until we are able to influence the education of a body of men whose studies naturally bring them into relation with the subject and who, when *united, are numerous enough and* powerful enough to sway public opinion. Only one such body of men exists—the medical profession When the study of heredity forms as regular part of the medical curriculum as anatomy and physiology, then, and not till then, will the laws of heredity be brought to bear on the solution of social problems. At present a specialist like Mr. Galton has a very limited audience, in effect it is composed of specialists like himself. The difficulty of his subject and the profound ignorance of the public deprive him of a large part of his possible influence for good. Until among medical men a systematic knowledge of heredity is substituted for a bundle of prejudices and close and clear reasoning for wild guess-work, the influence of men of his type, most unhappily, is not likely to extend much beyond the limits of a few learned societies.

The first essential towards a knowledge of the laws of heredity and the first essential towards the application of those laws to social questions is a clear grasp of the distinction which exists between what are known as inborn traits and what are known as acquired traits. Inborn traits are those with which the individual is born, which come to him by nature, which form his natural inheritance from his parents. Acquired traits are alterations produced in inborn traits by influences to which they are exposed during the life of the individual. Thus a man's limbs are inborn traits, but the changes produced in them by exercise, injury, and so forth are acquired traits. All men know that the individual tends to transmit his inborn traits to his offspring. But it is now almost universally denied by students of heredity that he tends to transmit his acquired traits. The real, the burning question among students of heredity is whether changes in an individual caused by the action of the environment on him tend *in any way* to affect the offspring subsequently born to him. Thus, for example, does good health in an individual tend to benefit the offspring subsequently born to him; does his ill health tend to enfeeble them?

---

[1] Dr. Cammidge; Arris and Gale lecture, THE LANCET, March 19th, 1904, p. 782.

It is generally assumed that changes in the parents do tend to influence the inborn traits of offspring. Thus we have heard much of the degeneracy which it is alleged is befalling our race owing to the bad hygienic conditions under which it dwells in our great and growing cities. The assumption is made that the race is being so injured by the bad conditions and that the descendant of a race of slum-dwellers, if removed during infancy to the country, would on the average be inferior physically to the decendant of a line of rustics; whereas, contrariwise, the decendant of a line of rustics, if removed during infancy to the slums, would be superior physically to the majority of the children he would meet. I believe the assumption to be a totally unwarrantable one. It is founded on a confusion between inborn and acquired traits. Of course the influences which act on a slum-bred child tend to injure him personally. But there is not an iota of evidence that the descendant of a line of slum-dwellers is on the average inferior to the descendant of a line of rustics whose parents migrated to the slums just after his birth. I believe, in fact, while a life in the slums deteriorates the individual it does not affect *directly* the hereditary tendencies of the race in the least. A vast mass of decisive evidence may be adduced in support of this contention. Slums are not a creation of yesterday. They have existed in many countries from prehistoric times. Races that have been most exposed to a slum life are not inferior physically and mentally to those that have been less or not at all exposed. The Chinese, for example, who have been more exposed and for a longer time to their influences than any other people, are physically and mentally a very fine race and certainly not inferior to the Dyaks of Borneo for example. There is also a mass of collateral evidence. Thus Africans and some other races have been literally soaked in the extremely virulent and abundant poison of malaria for thousands of years. We know how greatly malaria damages the individual. But Africans have not deteriorated. Like the Chinese, physically, at any rate, they are a very fine race. Practically speaking every negro child suffers from malaria and may perish from it. The *sufferings* of the negroes from malaria have produced no effect on the race but the *deaths* of the negroes from malaria have produced an immense effect. The continual weeding out during many generations of the unfittest has rendered the race pre eminently resistant to malaria, so that negroes can now flourish in countries which we, who have suffered very little from malaria, find it impossible to colonise. Similarly the inhabitants of Northern Europe have suffered greatly for thousands of years from consumption, especially in places where the population has been dense, where there have been many cities and towns and therefore slums. They also have not deteriorated; they have merely grown pre eminently strong against consumption. They are able to live, for example, in English cities in which consumption is very rife and which individuals of races which have been less exposed to the disease find as dangerous as Englishmen find the West Coast of Africa. During the last 400 years consumption has spread very widely and now no race is able to live in cities and towns in cold and temperate climates that has not undergone evolution against it. In other words, no race is capable of civilisation that has not undergone evolution against consumption, as well as other diseases and influences, deteriorating to the individual, which civilisation brings in its train. Many biologists and most medical men believe that influences acting on parents tend *directly* to alter the hereditary tendencies of offspring. In technical terms they believe that variations are caused by the action of the environment. How they can contrive to do so in the face of the massive and conclusive evidence afforded by the natural history of human races in relation to disease is beyond my comprehension. How could a race undergo evolution against malaria, for example, if parental disease altered and injured the hereditary tendencies of the offspring? How could natural selection select if all variations were unfavourable? The observations on disease and injury published by Brown-Séquard, Cossar Ewart, and many medical men are capable of an interpretation entirely different from that which they gave.

Mr. Galton speaks as if the causes which brought about "the disappearance of most savage races when brought into contact with high civilisation" were obscure. I can assure him, however, that they had been worked out precisely and statistically by medical observers on the spot. Apart from extermination by war the only savage races which are disappearing are those of the New World and in every instance they are perishing from the enormous mortality caused among them by introduced diseases against which their races have undergone no evolution. He will find these precise statistics in the tables of mortality issued by all the public health departments that exist in America, Polynesia, and Australasia. He will find also many accounts in the journals of travellers. If he will read the records of visits of parties of aborigines from the New World to the cities of Europe he will find that their mortality, especially from consumption, was invariably high. There is nothing more obscure about the disappearance of these races than there is about the disappearance of the dodo and the bison. They are perishing, not because, as Froude poetically put it, they are like caged eagles incapable of domestication. They do not wilt away mysteriously. They perish simply and solely because they are weak against certain species of bacteria which flourish especially well under the conditions of civilised life. If malaria, instead of consumption, were prevalent in cities then the English would be incapable of civilisation, whereas the negroes and the wild tribes about the Amazon and in New Guinea and Borneo would be particularly capable of it. Indeed, it may be taken as a general rule to which there is absolutely no exception that every race throughout the world is resistant to every disease precisely in proportion to its past experience of it and that only those races are capable of civilisation which are resistant to the diseases of dense populations.

Before the voyage of Columbus hardly a zymotic disease, with the exception of malaria, was known in the New World. The inhabitants of the Old World had slowly evolved against their diseases under the gradually worsening conditions caused by the gradual increase of population. They introduced them to the natives of the New World under the worst conditions then known. They built cities and towns, the natural breeding places of all zymotic diseases except those of the malarial type. They gave the natives clothes which are the best vehicles for the transport of microbes. They endeavoured to Christianise and to civilise the natives and so drew them into buildings where they were infected. They forced them to labour on plantations and in mines. In fact, they forced on them every facility for "catching" disease. As a result they exterminated, or are exterminating, them. The natives of the Gilbert Islands lately petitioned our Government not to permit missionaries to settle among them as they feared destruction. They were perfectly right. Clothes and churches and school rooms are fatal to such people. The Tasmanians before they were quite exterminated had a saying that good people—that is, people who went frequently to church—died young; they also were perfectly right. It is a highly significant fact that, whereas every white man's city in Asia or Africa has its native quarter, no white man's city in the New World has its native quarter. To find the pure aborigines of the New World we must go to parts remote from cities and towns. They cannot accomplish in a few generations an evolution which the natives of the Old World accomplished only after hundreds, perhaps thousands, of generations and at the cost of thousands of millions of lives. The negroes who were introduced into America to fill the void created by the disappearing aborigines have persisted; but they have already undergone some evolution against the chief disease of civilisation, consumption, and much evolution against measles and other diseases. Yet the negroes would not have persisted had they not been introduced under special conditions. They were taken to the warmer parts of America at a time when consumption was little rife as compared to its prevalence in the cities of Europe and they were employed mainly in agricultural occupations. They had a special start and were placed under conditions which worsened only slowly. As a result they underwent evolution and are now able to persist in America. But African negroes, as compared to the natives of the densely populated parts of Europe and Asia, have undergone little evolution against consumption. As a consequence no African colony has ever succeeded in Europe or Asia. For instance, the Dutch and English imported about 15,000 negroes into Ceylon a century ago. Within 20 years all, except a mere handful, had perished mainly of consumption and that is a country where the disease is not nearly so prevalent as in Northern Europe or the more settled parts of Northern Asia.

There can be little doubt that the sterility of New World races when brought in contact with civilisation is due mainly to ill health. The sterility of our upper classes, as any medical man will inform Mr. Galton, is mainly voluntary. *It is due to the possession of special knowledge. The growing sterility of the lower orders* is due to the spread of that knowledge; hence the general and continuous fall in the birth-rate. Until we are able to estimate the part played by this knowledge it would be vain to collect statistics of comparative fertility. We have frequently been told that no city family can persist for four generations unless fortified by country blood. That, I believe, is a complete error. Country blood doe t weakens it; for it has been elements. It is true, owing to the great immigration from the country, it is difficult to find a city family which has had no infusion of country blood for four generations. But to suppose on that account that country blood strengthens city blood against the special conditions of city life is to confuse *post hoc* with *propter hoc.* Slum life and the other evil influences of civilisation, including bad and insufficient food, vitiated air, and zymotic diseases, injure the individual. They make him acquire a bad set of traits. But they do not injure the hereditary tendencies of the race. Had they done so, civilisation, which implies a dense population, would have been impossible. On the contrary, by weeding out the unfittest they make the race strong against those influences. If, then, we wish to raise the standard of our race we must do it in two ways. In the first place, we must improve the conditions under which the individual develops and so make him a finer animal. In the second place, we must endeavour to restrict as much as possible the marriage of the physically and mentally unfit. In other words, we must attend both to acquired and inborn characters. By merely improving the conditions under which people live we shall improve the individual but not the race. The same measures will not achieve both objects. Medical men have done a good deal for the improvement of the acquired characters of the individual by improving sanitation. They have done nothing towards the second object, the improvement of the inborn traits of the race. Nor will they do anything until they have acquired a precise knowledge of heredity from biologists. On the other hand, before biologists are able to influence medical men they must bring to bear their exact methods of thought on the great changes produced in various races by the experience during thousands of years of disease. I am sure our knowledge of heredity will gain in precision and breadth by a consideration of these tremendous, long-continued and drastic experiments conducted with such momentous results by nature. No experiments conducted by man can compare with them in magnitude and completeness. As I have already intimated, the precise statistical information on which our conclusions may be based are already collected and tabulated. I am sure it is good neither for medicine nor biology that medical men and biologists should live in separate and closed compartments, each body ignoring the splendid mass of data collected by the other. Much of medicine should be a part of biology and much of biology a part of medicine.

I am, Sirs, yours faithfully,

Southsea, May 30th, 1904. G. ARCHDALL REID.

ABSCESS OF THE FRONTAL SINUS.

To the Editors of THE LANCET.

SIRS,—I read with much interest Mr. Herbert Tilley's article in THE LANCET of May 21st, 1904, p. 1414, on Some Experiences in the Surgical Treatment of Suppurative Lesions of the Nasal Accessory Sinuses; also I had previously read with interest his article in THE LANCET of July 14th, 1900, p. 100, on Empyema of the Frontal Sinus; but I should like to draw his attention to two short but admirable papers by Mr. Charles Higgens on Distension of the Frontal Sinus in the Guy's Hospital Reports for 1880–81 and 1893. In the earlier paper Mr. Higgens describes with admirable lucidity a small round fluctuating swelling which forms when the bone has become absorbed in cases of long-standing distension of the frontal sinus at the inner angle of the orbit and *which resembles a distended lacrymal sac*, but is situated above the tendo oculi instead of below it and which cannot, like the distended sac, be emptied by pressure nor can any of its contents be squeezed through the canaliculi. It also has one marked peculiarity—it varies in size at different times in the day.

I have recently seen a case where this swelling was very noticeable This swelling only occurs in cases where the *bone has become absorbed and the contents of the sinus* project through a hole in the bone beneath the integuments. When present this swelling is of the greatest importance both for diagnosis and treatment. In one of Mr. Higgens's cases "an exploratory incision showed the swelling to be a distended frontal sinus containing white viscid mucus. A probe could be pushed into the cavity a distance of three inches; its breadth appeared to be about one inch."

With regard to treatment, when this swelling is present all that is necessary to do is to make an incision through the swelling and pass a drainage tube into the cavity of the nose. There is obviously in this operation no danger to life, whereas if the trephine is used the freshly cut surface of the diploë is liable to absorb septic material and consequently occur osteomyelitis, meningitis, and death. Mr. Higgens has known all about this small swelling for a quarter of a century, but notwithstanding his two papers in the Guy's Hospital Reports even the greatest nasal specialists seem still to be entirely ignorant as to its nature, nor can I find anything about it in any book.

With regard to the treatment after opening the frontal sinus I fully agree with Mr. Tilley that "from the moment the operation is completed the motto of the surgeon must be, '*Free, unhindered, spontaneous drainage,*' and *if* he secures this he need never fear that any serious harm may come to his patient." I entirely fail, however, to see the desirability of the complete obliteration of the frontal sinus which Mr. Tilley recommends. It is naturally a cavity and, I think should remain so if free drainage is secured.

I am, Sirs, yours faithfully,

Beckenham, May 31st, 1904. ROBERT S. WAINEWRIGHT.

THE INFECTIVITY OF SCARLET FEVER.

To the Editors of THE LANCET.

SIRS,—The above subject having lately been much under discussion, the following, taken from the *Medical World* of Philadelphia for February, 1902, may be of interest:—

"In the spring of 1900 a family of children had scarlet fever and though very severe none of them died. During the desquamation whole casts of fingers and toes came away. ...... The mother collected a quantity of these and placed them in a pasteboard box. Having moved to my neighbourhood they were visited in February, 1901, by a family consisting of father, mother, and boy, three years of age. The conversation turning upon scarlet fever the hostess brought out her box of "relics" and exhibited the contents to her visitors, making a special display for the benefit of the boy. ...... On the fourth day following the child had a chill, developing into a very malignant type of scarlet fever. A sister of the child's mother visited the patient from the second to the fifth day with her three children; also the father's brother visited the boy on the third day with his four-year-old boy. The visiting families lived 15 miles away. ...... No other children in the community were exposed and no others had the disease, while everyone that was exposed had scarlet fever in its worst form and every one of them died." The above was reported by Dr. W. R. Fowler of Pottsville, Texas.

I am, Sirs, yours faithfully,

ARTHUR E. GRESHAM, M.D.

Sierre Madre, California.

EXTRAORDINARY CASE OF SUICIDAL CUT-THROAT.

To the Editors of THE LANCET.

SIRS,—The extraordinary features of a case of suicidal cut-throat perhaps merit my encroaching on your valuable space. On June 2nd at 8.30 A.M. I received an urgent call to a man who had attempted suicide by cutting his throat. On my arrival I found the patient to be a man of good physique, quite conscious but aphonic. He lay on the kitchen sofa with a wound in his throat. This cut was some five inches in length. It had been self-inflicted but had necessitated more than one gash to cause it, judging from the ragged ends. The exceptional feature of the case, however, was that the entire larynx with the hyoid bone was conspicuous by its absence. The trachea had been completely severed but the œsophagus was intact. The patient was very blanched and *in extremis.* His carotid and jugular vessels had escaped. His end came a few minutes after my arrival. The deed had been committed an hour before I saw him in an out-house with a blunt penknife and on going there I found on the floor the entire larynx with the hyoid bone. With the exception of an indentation in the cricoid where the knife had struck it they were all in perfect condition. The intrinsic muscles were intact but those attached to neighbouring parts had been severed with the knife. The dissection of the larynx was very wonderful. What determination the man must have possessed to have undergone the agony and torture of excision of his own larynx! The patient had been drinking heavily for some ten days prior to his death. The homicidal impulse of alcoholism, associated with mutilation, seems to me more potent than that of any other form of mania.

I am, Sirs, yours faithfully,

W. MACALISTER BROWN, M.B., Ch.B. Glasg.

Crewe, June 4th, 1904.

THE OLD HARDSHIP OF LONDON MEDICAL STUDENTS.

To the Editors of THE LANCET.

SIRS,—I the more readily sympathise with your correspondent "Hard Lines" (May 21st) since I have had a very similar experience to his at the London University. Returning to England after some years' practice in the tropics I presented myself (for the first time) at the recent M.B. examination. I was rejected in obstetrics and, like your correspondent, was not marked "weak" in any other subject. The gynæcological questions may interest practitioners. There were two:—1. "What are the varieties of urinary fistulæ? Give their causes, diagnosis, and treatment." 2. "Give an account of tumours originating in the vaginal wall. How would you diagnose and treat them?" Despite the examiners' verdict I confess, since I am writing anonymously, that I still consider myself a fairly competent accoucheur. Abroad my midwifery practice was almost entirely operative, one being rarely called to a normal labour. In the eight months I have been in my present practice my midwifery cases comprise three transverse presentations, one multiple (foot and hand), one high forceps operation for contracted pelvis, one placenta prævia, and one case of post-partum hæmorrhage (rather severe). To most of these (including the last) I was called by midwives. I have had no maternal deaths and two stillbirths in transverse presentations to which I was called long after the membranes had ruptured. As it also happens I have operated on four cases of vesico-vaginal fistulæ due to the effects of prolonged unaided labour. (These cases, of course, are commoner in the remote districts of the world where help cannot be obtained, sometimes through such physiographical causes as flooded rivers, &c.) In three I had a perfectly successful result. I admit my operations were not classical ones; they had to be done with such assistance and material as one can command in places far removed from the great centres of civilisation.—I am, Sirs, yours faithfully,

June 1st, 1904. FAILED M.B.

HEALTH OF CORNWALL.—The sanitary committee of the Cornwall County Council, in its annual report for 1903 states that 7319 births were registered during the year, giving a rate of 22·69 per 1000, as compared with 23·82 per 1000 the average birth-rate for the last five years. The birth-rate for 1903 was the lowest the committee had recorded. There were 4578 deaths registered, giving a general death-rate of 14·21 per 1000, as compared with 16·72 per 1000 recorded in 1902. 832 cases of infectious disease were notified, against 925 in the previous year. 445 deaths occurred from phthisis and 106 from other forms of tuberculosis, compared with 473 and 119 respectively in 1902.

THE FOLKESTONE PUBLIC HEALTH CONGRESS AND THE SANDGATE SCANDAL.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

THE next congress of the Royal Institute of Public Health will meet from July 21st to 27th at Folkestone. Though the date is badly chosen—for it clashes with the meeting of the British Medical Association and of the British Sanitary Institute—it is in one respect fortunate that a congress dealing with public health questions is about to be held at Folkestone. Certainly there is not much of interest from the sanitary point of view at Folkestone except it be that the sewer outfall is badly placed, but a new and most important problem may be studied close at hand. Sandgate is within two miles of Folkestone, public vehicles ply backwards and forwards constantly, and at Sandgate we hav a sanitary grievance involving the widest issues. The chief features of this question have already been described,[1] though there are some fresh developments, and the matter has now been brought to the notice of the Government. It is true that the first appeal has failed to induce the Government to take action, but Governments generally need a great deal of awakening before they move in such matters. For this very reason the congress about to meet at Folkestone might render a great service. In the section devoted to preventive medicine no better subject could be found for discussion than the question of the cost to the community that may be caused when phthisical patients are gathered together and in large numbers, not in hospitals but in private houses, not on an isolated spot but in the centre of a town. This is precisely what is taking place at Sandgate.

The facts should be well known by this time. The population of Sandgate does not exceed 2000 and yet this small community had to receive during the course of last year no less than 897 patients suffering from pulmonary tuberculosis. These patients were not isolated but lived in private houses in the town itself and took their exercise in the streets or on the beach among the ordinary inhabitants. These private houses belonged to the late Mr. J. J. Jones and were organised on a purely speculative basis just as so many hotels or lodging-houses. There were 45 deaths from phthisis last year, of which 43 occurred in Jones's homes. Then there were five deaths from other causes in these homes and 14 deaths among the general population. Of course, the patients only remain a few weeks or at most a few months in the homes at Sandgate. Adding together these numerous short visits it is reckoned that they equal an average number of 180 tuberculous patients present all the year round and there were 45 deaths from phthisis. It is evident that many came when the disease had reached an advanced stage and when the risk of infecting others was greatest. Dr. Ballastre, whose public functions at Nice are somewhat similar to those of an English medical officer of health, bears witness that on the Riviera the prevalence of tuberculosis among the native population has increased since so large a number of tuberculous patients from all parts of the world have wintered at Nice, Mentone, and adjoining health resorts. The population of Sandgate is naturally much concerned to find their streets invaded by phthisical patients. Not only do they fear for their own health but all these sick people alarm the ordinary visitor; consequently the lodging-houses are empty and the tradesmen make but poor receipts.

Nevertheless, the Local Government Board first of all refused to hold an inquiry into the matter. Then when the question was pressed forward in the House of Commons by the local Member, Sir Edward Sassoon, Mr. Long replied that he did not feel satisfied that more extensive powers were required, adding that a consumptive patient was more dangerous to the public when not confined in a home. This reply clearly proves that the points at issue are not yet understood, at least by the head of the Local Government Board. One of the great arguments in favour of sanatoriums for tuberculosis, and the one argument of all others which has met with no contradiction, is exactly what Mr. Long himself brought forward—namely, that a consumptive patient is more dangerous to the public when not confined to a home. The patients at Sandgate are not confined to homes;

---

[1] See THE LANCET, August 22nd, 1903, p. 565.

they live in boarding-houses and frequent the public streets. Grave doubts have been expressed as to whether sanatoriums were of much benefit to the patients themselves, but everyone agrees it is a good thing for the public that tuberculous patients should be taken away from their usual surroundings. It has been pointed out that even though after a few weeks or months they return to their private homes and there ultimately die from the disease still their brief sojourn in a sanatorium will prove of use to the public if not to the patients. The reason is obvious; first, while at the sanatorium they are out of harm's way, and secondly, they then learn how to take care of themselves, how to value the open air and open windows, and how to take precautions so as to insure the disinfection and destruction of their sputum, so that altogether, even though they may return to the community without having obtained much benefit from the treatment, they have at all events been taught how to avoid imperilling their neighbours. But it is precisely because this is not done at Sandgate that the grievance arises. In the technical sense—and that is the only sense which bears on the question—there is no home or sanatorium at Sandgate and the patients are not isolated in any such institution. The patients live in ordinary private dwelling houses situated in the main street, their walls touching the walls of other houses. Most of these dwellings have no gardens and no place whatsoever for the inmates to take exercise. Instead of being isolated the patients live in these ordinary houses and in the streets, mingling all day long with the general population and the soldiers from Shorncliffe Camp. Inside these private houses there is no real medical and prophylactic treatment or discipline such as is associated with the idea of a sanatorium. To begin with, it is in no one's interest to impose such a régime. The only object is to run the whole affair at the least, possible trouble and cost, so that there may be the maximum profit made out of the sums paid by or for the patients. If a sanatorium was built in its own ground on an isolated site in the neighbourhood of Sandgate and properly managed by responsible medical men no one would object. The complaint rests in the fact that more than 800 tuberculous patients have been sent to a small town during the course of the year, though there is no institution in the neighbourhood capable of receiving them. Consequently the patients have had to live in ordinary lodging-houses and in the centre of the town just as if they were healthy people.

During the last five years of the last century the annual average number of deaths from pulmonary tuberculosis in England and Wales was 1321·4 per 1,000,000 of the population, or 1·3 per 1000. The census puts the population of Sandgate down at 1995. To this figure two or three hundred may be added to represent the strangers who visit the place for a short time. Thus, for instance, if 800 patients remain at Sandgate for on an average three months each, this would equal an increase of population for the whole year round of 200. Nevertheless, even taking into account the increase of population due to the visitors who remain for a few weeks or months the deaths from pulmonary tuberculosis at Sandgate should not exceed three per annum; as a matter of fact, they amounted for the year 1903 to no less than 45.

Of course, if it could be said that the greater part of these deaths did not occur among the inhabitants of the town but in some large hospital or institution managed by a competent staff of medical men and situated in its own grounds well away from the general population it would not matter. But, on the contrary, these deaths all occurred in the main streets of the town, in various houses, and where there is no staff of medical attendants who can be held responsible for the patients. A medical man in the service of the Jones family does once a day look in at these various private houses where the patients are lodged but he lives at a considerable distance and it is difficult to find him when an emergency occurs. Considering that something like 1000 consumptive patients may go to Sandgate during the course of the year (there were 897 in 1903) there should be a sanatorium to receive them and a fully-qualified physician living on the premises armed with ample power in the management and treatment of this large number of patients. But then a properly constructed sanatorium would probably cost at least £200 per bed and from 25*s*. to 30*s*. per week per patient. A sanatorium of 100 beds would cost £20,000 to build. A private speculator like the late Mr. Jones could scarcely expect to get this money for less than 5 per cent., so he would have to allow £1000 a year for interest on capital. Actually the charge for board and what little treatment is given ranges from £1 1*s*. to £2 5*s*. per week per patient, according to the class or category to which they belong. If everything is done properly this sum would barely do more than cover the working expenses. Even if there was a slight profit it would certainly not suffice to pay the interest on the capital. But then no one has ever pretended that sanatoriums of this description could be made paying concerns and the mere fact that these Jones's homes are run for profit is in itself a sufficient proof that they cannot be properly conducted. Homes for wealthy patients who can afford to pay from £3 3*s*. per week and upwards, not to mention many extras, may yield a profit. The Jones's homes at Sandgate take in paupers for £1 1*s*. per week; second-class paying patients at 25*s*. or 33*s*. if a private bedroom is required; and first-class patients at 35*s*. and 45*s*. if they have a private room. Mr. Jones said that he had 126 beds reserved exclusively for phthisical patients. The popular sanatorium recently built at Borgoumont for the poor of the province of Liège, which contains 114 beds, cost £52,000. Will anyone credit the late Mr. Jones with having spent anything like that sum over the 126 beds he provided for tuberculous patients at Sandgate? If not, why not, and in what consists the difference? and why should such a large expenditure be judged necessary in Belgium for identically the same class of people who in England are entrusted to the tender mercies of the Jones family? The English were thought to be far and away ahead in all matters of sanitation, but here things have been allowed to drift into unqualified hands who have only seen that the outdoor treatment of tuberculosis afforded a means of securing lodgers and of making money out of them.

Poor-law boards of guardians have been circularised and so also have private practitioners. They have been led to infer that there were sanatoriums at Sandgate where tuberculous patients could receive outdoor treatment for a very moderate charge. So it was said that the Jones's homes supplied a want and of course there is always a demand for cheapness. Consequently, and as an easy way of getting rid of troublesome cases, some boards of guardians have been reckless enough to send their tuberculous paupers to these homes. The whole question of sanatoriums and the outdoor treatment of consumption has been studied with the greatest care and many millions of private and public money have been spent in making scientific experiments that extend over hundreds of thousands of cases in Germany, France, Switzerland, and other parts of the continent. At Sandgate, however, this most serious question became a matter of very ordinary speculation. If, nevertheless, this is not serious enough to attract the attention of the Local Government Board perhaps the War Office will be more interested in the matter. Grosvenor House with its 46 beds for pauper patients and Farleigh House and Lymington House with their 49 beds for paying patients face the sea front promenade. The windows overlook the main road that goes from Folkestone to Hythe. The dust blows out from these three houses, which are almost side by side and which hold 95 tuberculous patients, on to the people that pass underneath on this the most frequented thoroughfare of the neighbourhood. Among all these people there are a considerable number of soldiers. Immediately behind *these houses* commences the ascent up to Shorncliffe Camp. The beginning of the camp grounds is about 500 feet away and the first barracks about 1000 feet [illegible]

[illegible] people die in Grosvenor House, there is better accommodation for laying out the corpses, besides there are only paupers at Grosvenor House and presumedly it does not matter about disturbing them. But Farleigh House holds the first-class paying patients. On the other hand, if a patient pays the first-class tariff is it not a breach of contract to disturb him in his last moments and drag him out into the street so that he may be taken to die among the paupers of Grosvenor House? The people who are endeavouring to keep lodging-houses side by side with these so-called homes were shocked by the ghastly sight when dying patients were thus carried from one house to the other. This occurred towards the end of last February. Not far from here there is a public-house frequented by soldiers and it used also to be [illegible] by women from one of Jones's homes. It is said that these women were able to return late at night to the home till an officer wrote from the camp and complained and then a better watch was kept. If the President of the Local Government Board has no objection to so large a number of tuberculous patients being dumped down in the midst of a civil population, perhaps the Secretary of State for War may not relish the idea that in the course of a year the soldiers from Shorncliffe Camp are brought into close contact with from 800 to 1000 different cases of pulmonary tuberculosis. Mr. Long said in the House that it is better for such patients to be in a home than at large. But at Sandgate they are at large—they are in the streets all day long; and all day long there are soldiers from the camp in the same streets, shops, on the beach, or in the public-houses, standing or passing close by, or talking to the patients from Jones's so-called homes. These patients are supposed to have outdoor treatment and therefore they are sent out into the streets as often as possible.

The contrast that this state of affairs presents with what has been done on the continent is most discreditable to a country like England. The matter of sanatoriums for tuberculosis was discussed at great length so recently as the International Congress of Hygiene which met at Brussels last year. Being so close to Sandgate it is obvious that the visitors to the forthcoming Folkestone Public Health Congress must also discuss the matter and examine the grievance for themselves. They will thus be able to render a great and practical service. To facilitate this task it may be useful to set forth some of the principal facts and arguments which were brought forward at Brussels by men who in different countries of the world had made a special study of the subject.

(*To be continued.*)

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Sleeping Sickness: the Liverpool Expedition to the Congo.

THE expedition despatched to the Congo Free State in the autumn of 1903 under the auspices of the Liverpool School of Tropical Medicine for the purpose of studying trypanosomiasis and the cause of sleeping sickness is doing a most useful work. The expedition consisted of Dr. J. E. Dutton, Dr. J. L. Todd, and Dr. C. Christy, the last named of whom was a member of the Royal Society's Commission sent to Uganda to investigate the cause of sleeping sickness. The expedition stayed at Boma until the end of the year. At Boma the Belgian authorities attached a State medical officer to the expedition, Dr. Heiberg, a former student of the Liverpool School of Tropical Medicine. After a stay of six weeks at Boma the expedition proceeded to Matadi, where it remained for a few days. Dr. Dutton and Dr. Christy then went through the cataract region, their tour lasting three weeks, when they joined Dr. Todd and Dr. Heiberg, who had preceded them, at Leopoldsville. A stay of four months was made there, the Government placing a spacious bungalow at the disposal of the expedition and subsequently building a hospital for the special study of cases of sleeping sickness. The members were thereby enabled to make careful observations of sleeping sickness under the most favourable conditions possible and to work without encountering the obstacles so frequently met with by expeditions in similar climes who have not had the opportunity of remaining for a sufficient length of time in a suitable district in such favourable circumstances. As the cases of the sickness were very numerous a great amount of material was available and the expedition was able to study closely the different types of the disease. The expedition speaks in the highest terms of the unfailing courtesy and ready assistance it has received everywhere from the Belgian officials of every grade. Dr. Christy left for Rome on May 1st, the other members, Dr. Todd and Dr. Dutton, proceeding up the Congo river, where the expedition will continue its researches in the little known regions of the interior. Dr. Christy brought to Southampton by the s.s. *Anverville* four natives suffering from sleeping sickness who were sent on in a special invalid coach to Liverpool, one of whom unfortunately died on the day following his arrival at Liverpool; the others are now in the Royal Infirmary. The *Anversville* also brought home a number of rabbits, monkeys, and rats sent out by the school which have been inoculated with the disease. These were sent on to Liverpool for investigation.

Mosquitoes and Malaria.

At the invitation of Major Ross, C.B., F.R.S., professor of tropical medicine at the University of Liverpool, a meeting of the Lancashire and Cheshire Entomological Society was held in the Johnston Laboratory of the University on May 23rd. A tour of the extensive laboratory with its attendant menagerie was made, after which Major Ross and the staff of the Liverpool School of Tropical Medicine gave demonstrations on mosquitoes and other flies in connexion with tropical diseases. Among the many interesting exhibits described were preparations of serum for protection against diseases, tubes of various bacteria, models of an Indian village and a larger district to show the natural distribution of the typical breeding grounds of malarial mosquitoes, a microscopic exhibition of malaria germs in various stages of growth, live trypanosomes of the sleeping sickness and tsetse-fly diseases, specimens of the tsetse-fly (glossina morsitans), &c.; also a series of microscopic preparations showing the characteristic differences in appearance and structure existing between the malarial and harmless gnats. An adjournment was afterwards made to the lecture theatre where Major Ross gave an instructive and interesting lecture on the connexion between malaria and mosquitoes, copiously illustrated by lantern slides.

The Linnæan Society.

At the annual meeting of the Linnæan Society held on May 24th Professor William A. Herdman, F.R.S., F.L.S., professor of natural history at the University of Liverpool, was elected president for the ensuing two years.

The New Professor of Physical Chemistry at the University of Liverpool.

Mr. F. J. Donnan, Ph.D., M.A., who was recently appointed to the chair of physical chemistry lately founded by Sir John Brunner, Bart., is a graduate of the Royal University of Ireland and was trained in the laboratories of Leipsic and Berlin. He was afterwards associated with Sir William Ramsay of University College, London, for about three years, first as his assistant in the department of chemistry and then as assistant professor. Dr. Donnan was subsequently elected to a junior fellowship at the Royal University of Ireland and is now lecturer at the Royal College of Science, Dublin. As an original investigator he takes a high place. The development of chemistry on the physical side has been so rapid and so important in its practical applications that Sir John Brunner was prompted to establish the chair at the University of Liverpool.

The Royal Infirmary: the John Lawrence Memorial.

At an influential and representative meeting held in the town hall on May 27th, the Lord Mayor presiding, it was resolved to provide a memorial of the many services rendered to the city by the late Alderman John Lawrence, the memorial to take the form of the endowment of a bed in the Royal Infirmary, with which charity he had been closely identified for 22 years. It is hoped to raise £1200, as the annual maintenance of the bed would cost about £54.

St. Helen's Sanatorium.

The new extensions to the St. Helen's corporation sanatorium at Peasley Cross were formally opened on May 26th by the Mayoress of St. Helen's. The enlargement consists of two pavilions, a discharging ward, a new mortuary, and 16 additional bedrooms, the total area now covered being upwards of five acres. The total amount expended by the corporation since the opening has been £23,600. The number of patients admitted last year was 516, but the hospital is capable of dealing in times of emergency with 130 patients. The whole of the extensions have been erected in accordance with the requirements of the Local Government Board and in the most up-to date manner. The institution is now completed with the exception of further laundry accommodation and the possible extension of the administrative block.

June 7th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Death of Lord Powerscourt.

Viscount Powerscourt who died at his London residence on June 5th had filled many positions of public honour and usefulness, and among others the post of chairman of the board of superintendence of the Dublin hospitals.

Rotunda Hospital, Dublin.

Mr. Francis T. Heuston, senior surgeon, Adelaide Hospital, has been appointed by the board of governors of the Rotunda Hospital as consulting surgeon in succession to the late Sir Philip Crampton Smyly.

Jervis-street Hospital, Dublin.

At a special meeting of the governors and guardians of Jervis-street Hospital held on May 31st Mr. Denis Kennedy, surgeon to the Children's Hospital, Temple-street, was elected unanimously to the position of visiting surgeon to the institution.

Dublin Sanitary Association.

The annual report of the Dublin Sanitary Association appeared on May 18th and deals with the insanitary condition of a number of the national schools both in Dublin and in several parts of the country. It calls attention to the fact that it is useless to expect that the very best domestic management in the houses of the working classes will safeguard health in the south of the city so long as the children are compelled to attend [illegible] the sanitary arrangements a [illegible] and objectionable character. [illegible]rt of the equivalent grant for [illegible]ge be allocated to the improvem[illegible] of the national schools throughout Ireland. The report goes on to call attention to the abnormal infant mortality as evidenced by the fact that during the 13 weeks ending January, 1904, out of a total of 108 deaths registered of persons the cause of whose death was uncertified 69 were children under five years of age.

Health of Belfast.

At the city of Belfast corporation meeting on June 1st it was reported that in the four weeks ended May 14th 51 cases of scarlet fever, 39 of typhoid fever, 31 of erysipelas, 20 of simple continued fever, 29 of diphtheria, five of typhus fever, four of small-pox, and three each of puerperal fever and membranous croup had been notified. The average annual death-rate was 21·6 and while a large number of cases of infectious disease was notified the deaths were but few. Small pox still continues and there are at present 12 cases in hospital, and 25 persons who were more or less in contact with the disease are under observation at the reception house at the Twin Islands. Four of these new cases were due to concealment. The public health committee urges revaccination and [illegible]ld, where suspicious cases of [illegible] at once with the health departm[illegible]

The Belfast Workhouse.

Mr. Agnew, Local Government Board inspector, has recently reported on the condition of the Belfast workhouse for the past half year. He refers especially to the overcrowding of the wards which prevents the medical officers making a better classification of diseases in the infirmary.

Visit of the Lord Lieutenant of Ireland to Belfast.

During the recent stay of the Lord Lieutenant of Ireland in Belfast he visited on June 3rd the Royal Victoria Hospital, where the following members of the medical staff were presented to him: Mr. J. W. Browne, Sir W. Whitla, Professor J. W. Byers, Dr. H. L. McKisack, Dr. W. Calwell, Mr. A. Fullerton, and Dr. W. Rankin. His Excellency also visited the Mater Infirmorum Hospital, where Dr. A. Dempsey, Dr. P. O'Connell, Dr. J. B. Moore, Dr. J. W. Killen, Dr. W. J. Maguire, Mr. P. J. H. Mulholland, and Mr. W. McLorinan, members of the visiting medical staff, were presented to him. In both institutions he made a careful inspection and expressed himself as much pleased with all that he saw.

The Belfast Medical School.

There are 111 students attending hospital this summer as against 118 in the last summer session, while during the past winter (1903-04) there were 149 as against 139 in the previous session, so that practically the numbers are, taking summer and winter together, almost the same in both years. Mr. J. A. Lowry has been awarded the Coulter exhibition and Mr. R. Chambers (first) and Mr. W. A. Magill (second) the Malam exhibition.

June 7th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Carbon Dioxide Baths.

AT the meeting of the Academy of Medicine held on May 24th M. Laussedat discoursed upon the effects of the carbon dioxide bath—that is to say, a bath taken in water highly charged with the gas in question. Myriads of small bubbles are given off which excite the skin and produce a marked reaction which can be utilised with great advantage as a therapeutic method. The Nauheim baths owe their reputation to this disengagement of gas but the value of the said baths has been much questioned. In a general way they excite the nervous system and have a marked effect in raising the blood pressure. But although treatment by these baths has met with numerous successes in cases where the blood pressure was too low, such as neurasthenia, anæmia, and certain cases of cardiac valvular disease, yet, on the other hand, they have been found to be harmful in cases where they were prescribed without due consideration for patients in whom the arterial tension was high, for in such the gravest symptoms have arisen. M. Huchard and M. Albert Robin have many times inveighed against the disastrous tendency of sending all and sundry cases of cardiac disease to Nauheim, a practice which is responsible for many deaths every year, either at Nauheim itself or on the patient's return. M. [illegible] bath does not raise th[illegible] a certain manner; th[illegible]ry quickly at a low temperature or at a fairly high one and the bath must only be given for a short time. If, on the other hand, the bath be given at a temperature of 34° C. and for a long time, with the water stationary and not running, there is no *rise in the blood pressure* but a lowering thereof, so that in this way the baths may be given to patients with arterial sclerosis or aortic disease who cannot be treated at Nauheim.

The Radiography of Foreign Bodies.

At the same meeting of the Academy M. Terrier, for M. Contremoulins, read a paper dealing with the location of foreign bodies in the organism by means of the x rays. M. Contremoulins stated that since the publication of his first radiographic method in March, 1897, he had examined 83 patients and in 77 of these foreign bodies were extracted. The foreign body was left in the remaining six cases but not on account of any reason connected with failure of the radioscopy. The new method is claimed to be of special use in military surgery, for the operations of localisation and of extraction being completely separate the one from the other localisation can be carried out at any point on the field of battle and extraction at any other point. Thus the two operations can be carried on without the two departments concerned having to arrange the work between themselves. The new method brings about a great saving of time, for five minutes suffice to localise the foreign body and ten minutes at the most to map out the exact field of operation.

Facilities for Factory Workers Suckling their Infants.

I have often referred in the pages of THE LANCET to the movement which is taking place in France for the encouragement of breast-feeding of infants and a corresponding disuse of artificial feeding. M. Budin, president of the Association for the Protection of Infant Life (Lique contre la Mortalité Infantile), is naturally an active promoter of this movement. Up to the present time one of the principal obstacles to the breast-feeding of infants has been the fact that so many women are engaged in various industrial occupations. Some large employers of labour already give special facilities to such of their workwomen as happen to be nursing. They leave off work in rotation at certain hours and a room is provided where their infants are brought to them from the crèche for the requisite time. Bonuses are also granted to the mothers of the finest infants. The State, moreover, is disposed to follow this example in the factories connected with the various Ministries. M. Budin has obtained a definite promise that workwomen in the national factories will be permitted and encouraged to suckle their infants and arrangements are about to be made giving them all the necessary facilities.

Treatment of Epitheliomata by the X Rays.

At a meeting of the Société de l'Internat des Hôpitaux de

Paris M. Leredde showed two patients, one male and one female, suffering from epithelioma of the face which he had treated by means of the x rays. The male patient had a tumour larger than a mandarin orange which was destroyed in five sittings, two having a duration of one hour and three of 45 minutes. It was possible that the cure might be complete; there was no projecting part and there was copious formation of epidermis on the margins. The woman had for years been under treatment without success, principally by the method of Cerny-Trunecek. The epithelioma occupied the entire root of the nose from one eye to the other and even encroached on the right conjunctiva. After six sittings of 20 minutes each the ulceration diminished by a half, the pain disappeared entirely, and a complete cure was expected at an early date. These cases were interesting on account of the difficulty which extirpation of the diseased parts would have presented, particularly in the second case, in which extensive removal of the bones of the face could not have been avoided. X ray treatment was applicable to extensive epitheliomata and was often preferable to extirpation.

Operative Procedures in Certain Forms af Infantile Paralysis.

At the same meeting of the Société de l'Internat des Hôpitaux de Paris M. Péraire showed two patients on whom he had operated for conditions due to infantile paralysis. The first patient was a young girl in the doubled-up position known as "cul-de-jatte," which was corrected by the following operations: (1) lengthening, freeing, and suture of the tendo Achillis; (2) resection of the knee; and (3) cuneiform tarsectomy with complete removal of the astragalus. The second patient was a boy suffering from club-foot (talipes equino-valgus and equino-varus) and was treated by (1) suture of the tibialis anticus to the extensor proprius pollicis; (2) suture of the tendons of the lateral peronei to the tendo Achillis; (3) suture of the extensor communis digitorum to the tibialis anticus and to the extensor proprius pollicis; and (4) removal of all the bones of the tarsus.

Obituary.

Dr. Gilles de la Tourette, professor in the Paris Faculty, head of the medical service of the exhibition held in 1900, died at Lausanne on May 24th, aged 47 years. His health had been failing for four years. A pupil of Charcot, he was for a long time at the Salpêtrière Hospital and published a number of admirable researches on hypnotism and neuropathology. He was an officer of the Legion of Honour.

June 7th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Sleeping Sickness in German West Africa.

Dr. K. Hintze, Government medical officer at Togo, German West Africa, has published in the *Deutsche Medicinische Wochenschrift* a report on sleeping sickness which has lately become somewhat prevalent in that colony. He has learned from the natives that the disease appeared in the country about 30 years ago but in course of time became extinct. In 1895 sporadic cases reappeared, the first death occurring as early as 1896. Since that time about two cases happened every year till 1902 when there was a sudden increase. Since 1896 there have been 48 deaths from sleeping sickness. At present the disease seems to be decreasing, as Dr. Hintze only found ten patients in the districts which he visited. He describes headache as being the principal symptom in the beginning of the disease; it may be present either for some months or for a longer period and may be the only indication of what is impending. At a later stage the face becomes somewhat swollen and the mental state of the patients shows remarkable alteration, they neglect their work, avoid the society of their friends, and suffer from drowsiness, they speak very slowly and softly, and may even lose the power of speech for several weeks. Some exhibit mental aberration and according to a native missionary maniacal excitement is of occasional occurrence. Tremulousness of the trunk and extremities comes on at a somewhat early stage and generally continues till death. The patellar reflexes are sometimes increased, sometimes normal, and sometimes absent. The pulse-rate is by no means constant; rates varying from 59 to 140 per minute have been recorded. The appetite is said to be good but emaciation nevertheless soon sets in and the skin becomes of a pale grey colour. Swelling of the glands at the angle of the jaw and a vesicular or pustular exanthema are also observed. In the final stage there are contractures of the arms and legs, the head is retroflexed, the patients are unable to move, are somnolent, and must be artificially fed. Death is attended by deep coma with incontinence of urine and fæces. Recovery has never been observed; the time from the beginning of the first symptoms till death varies from four months to three years. All ages and both sexes are liable to the disease but the most usual age of the patients is from puberty to the fiftieth year. In some places sleeping sickness is believed to be contagious, in others not; it is remarkable that the disease has an obvious tendency to occur in certain families. Dr. Hintze has not been able to form a distinct opinion on this question; he draws attention to the fact that as cooking vessels, clothes, pipes, and similar articles are constantly used by the natives in common there is ample opportunity for infection. Circumstances rendered systematic pathological or bacteriological work impossible but he made some blood preparations and collected some samples of cerebro-spinal fluid in none of which did he find either bacteria or trypanosoma; the only remarkable feature observed in the blood was a relatively great number of eosinophile cells. In one case where a partial post-mortem examination was made the naked-eye appearances of the brain and spinal cord were normal.

The "Dispensaire Antituberculeux."

The so-called "Dispensaire Antituberculeux," which takes a prominent place among the measures adopted for the prevention of tuberculosis in France, is becoming more and more popular in Germany also. It will be remembered that at the "dispensaire," which is an invention of M. Calmette of Lille, tuberculous patients are instructed in the details of personal hygiene most necessary for them to know; their dwellings are disinfected by officials of the "dispensaire"; and when circumstances make it desirable they are supplied with clothing, bed-linen, spittoons, and other requisites. Moreover, they are informed which sanatoriums and convalescent houses are available for them. It is a principle of the institution that medical examinations and medical prescriptions are strictly excluded, so that the work of the patient's medical adviser is not interfered with. On the contrary, medical men are requested to send their patients to the "dispensaire" for information. In Berlin the first "dispensaire" was opened a year ago in connexion with the Royal University Polyclinic for Tuberculosis; the second was opened by the "Free Choice Association," and in course of time sick clubs and other associations followed that example. The movement is a very reasonable one. Although a "dispensaire" is not in a position to publish impressive statistical results in the way that a sanatorium does it undoubtedly serves a useful purpose and can be carried on at a moderate expense.

Female Students at the University of Berlin.

During the present summer semester at the University of Berlin 368 women are on the books as compared with 562 during the preceding winter semester, and 293 during the summer semester of 1903. Of these 107 are foreigners, among whom 60 Russians form the majority. The numbers attending the various faculties and classes are as follows: philology, philosophy, history, and general science, 256; natural science, 33; medicine, 26; political economy, 22; theology, 15; dentistry, 11; mathematics, 3; and law, 2. 38 of the ladies are married.

Public Health in Prussia.

The annual public health report for the kingdom of Prussia dealing with the events of the year 1902 has lately been issued by the Government medical department. The report states that the death-rate in 1902 was lower than in any preceding year since 1875; the principal cause of this satisfactory condition was that owing to the cool weather of the summer months there was a reduction in the infant mortality. The number of births was less by 6178 than in 1901, and it is remarked that since 1876 the number of births has permanently decreased, and especially in Berlin. On the other hand, the death-rate of the capital was smaller than that of the other districts, being 15·90 per 1000, whilst the province of Silesia, where the mortality was highest of all, had a death-rate of 23·35 per 1000. The measures taken for the

prevention of infectious diseases have contributed to diminish the mortality. This i
in the case of enteric fever, as
enabled the medical officers of he
in an early stage and to isolate patients promptly. The report directs attention to the work of the local sanitary authorities in the towns and rural districts with regard to disinfecting arrangements, water-supply, drainage, &c. The hygiene of dwellings was said to be showing decided, although *slow, progress.* Great improvements have been made in school hygiene. The hygiene of factories and the inspection of food were not found to be everywhere in a satisfactory condition.

June 6th.

Medical News.

THE LEAGUE OF MERCY.—On June 8th the Prince and Princess of Wales, Grand President and Lady Grand President of the League of Mercy, gave a garden
to which a large number of
and members of the League of
I. a meeting of presidents and
lady presidents of the league was held in the saloon when a report of the work of the league during the past year was read by Mr. J. Harrison, M.V.O., one of the honorary secretaries, and a list of the names of those to whom the order of the league had been awarded by the King was announced by the registrar, Colonel Knollys. The Prince of Wales cordially thanked the presidents and other workers of the league for the services they had rendered through it to the London hospitals and expressed his pleasure at having an *opportunity* of personally meeting those who had striven to make, and had succeeded in making, the organisation of the League of Mercy so successful. Their Royal Highnesses, at the conclusion of the proceedings, adjourned to the garden, where about 1000 guests had assembled. After making a tour of the grounds the Royal party presented the decorations of the order to those to whom the award had been sanctioned by the King. Lord Wolverton presented the recipients, some 39 ladies and gentlemen, to the Prince, who decorated them with the order and afterwards shook hands with them. Refreshments were served during the afternoon in a buffet in the grounds and the band of the Royal Marine Light Infantry played selections of music at intervals. The names of those who have this year been awarded the order of the league for distinguished personal service are as follows: H.R.H. Princess Alexander of Teck (lady president, Epsom—Esher), H.H. Princess Victoria of Schleswig-Holstein (lady president, Berkshire), the Countess of Dartmouth (lady president, Lewisham), the Lady Harris (lady president, Faversham), the Lady Florence Pelham-Clinton (representing H.R.H the Duchess of Albany, lady president, Deptford—Brockley), Mrs. Charles Wightman (lady president, Hampstead), Colonel Sir Edwin Hughes (president, Woolwich), Mr. Montagu Sharpe, D.L., J.P. (president, Brentford), Mrs. Bentall (lady vice-president, Maldon), Mrs. Pritchard Binnie (lady vice-president, South Paddington), Mrs. Bishop (*lady vice-president*, Woolwich), Mrs. Gerald Buxton (lady vice president, Epping), Mrs. Castle (lady vice-president, Kingston—Surbiton), Miss Cayley (lady vice-president, Fulham), Mrs. Chancellor (lady vice-president, Richmond), Mrs. N. Cox (lady vice-president, Fulham). Mrs. Dawson, lady vice-president, Woolwich), Mrs. Norfolk (lady vice-president, Deptford—Brockley), Miss Swindells (lady vice-president, Lambeth—Norwood), Mrs. Wilkinson (lady vice-president, North St. Pancras), Sir Theodore Martin, K.C.B., K.C.V.O (vice-president, Guildford), Mr. Wenman Blake (vice-president, Fulham), Captain T. W. Gunton (vice-president, North St. Pancras), Mr. R G. Edwal Locke (vice-president, Faversham), Mr. Randall Mercer (vice-president, Medway), Dr. H. G. Thompson (vice-president, Croydon), Mr. Frank Turner (vice-president, West Marylebone), the Marchioness Cassar de Sain (member, St. George Hanover-square), Miss Katie Browne (member, Fulham), Miss Dennistoun (member, Westminster), Mrs. Walter Farquhar (member, Westminster), Miss O. M. Gibbs (member, North Hackney), Miss Mildred Hope (member, Westminster), Mrs. Macnab (member, South Paddington), Mrs. Payne (member, Colchester), Mrs. Skinner (member, Epping), Mrs. R. Thorne Waite (member, North St. Pancras), Mr. G. W. Boorman (member, Medway), and Mr. J. Smewing (member, North St. Pancras). According to the charter under which the League of Mercy was founded in 1899, its object it to further the interests and to promote the adequate maintenance of hospitals and other institutions for the relief of sickness and suffering, and this was to be done especially by encouraging personal service on the part of large numbers of persons. The League of Mercy has, in the four years during which it has been in operation, contributed £32,000 to the King Edward's Hospital Fund and this part of its work appears to be now established on a firm basis with progressively increasing results. Moreover, the additional £100,000 or £150,000 per annum which the King's Fund was initiated *to secure for the hospitals seems* to be now within measurable distance of being attained.

NEW ST. MARY'S HOSPITAL, MANCHESTER.—On May 30th the old St. Mary's Hospital in Quay-street, Manchester, was finally closed and the patients were removed to the new building in Whitworth street, just across the street from the Oxford-road station. The hospital has done good work in Quay-street for more than 100 years but more space was required and the new hospital can accommodate 100 patients. The police ambulances were used for the removal of the patients, which was *carried out without any difficulty.* The new hospital is arranged with due regard to the views of modern science but its situation is not ideal. It is low, very subject to fog, extremely noisy from the enormous amount of traffic in the adjoining streets and from the railway station close by, and in dry weather the dust from the streets will be a great nuisance. The best that can be said for the situation is that it is in the midst of a poor population.

AMBIDEXTRAL CULTURE SOCIETY.—At the meeting of this society held on June 1st Miss Werner of King's *College delivered a lecture on* Ambidexterity among the Zulus and other African Tribes. She said that unfortunately she had very little direct evidence on the subject. In general, so far as her information went, the right hand was the one used by preference for actions which required one hand only or chiefly. There were, however, indications that the proportion of left-handed or ambidextrous persons was larger in Central Africa than in Europe, but sufficient facts were not at hand to say precisely what that proportion was. The linguistic evidence, drawn from the expressions used in various Bantu languages for the right and left hand respectively, went indirectly to show *that* a preference was on the whole given to the right hand, which was known as the "eating" or the "throwing," sometimes as the "great" or the "male," hand. The left was sometimes called the "female" hand, but in some languages it was denoted by a *word of* which it was not easy to discover the meaning and which might not denote inferiority. It was worth noting that, according the Rev. H. Barnes of the Universities' Mission to Central Africa, the Chinyanja words set down in his vocabulary for "right" and "left" hand respectively were really used for the more and less used hands whichever these might happen to be. This implied a certain prevalence of left-handedness but not of ambidexterity.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—The annual meeting of the Fellows was held on June 4th, Sir Lambert H. Ormsby, the President, being in the chair. The report of the council was submitted and adopted. It was explained by the President that the receipts were with two exceptions the best for the past ten years. The College had recently expended over £1200 in painting and so on; this was paid off and at the date of the report the College was entirely free from debt and had a *bank credit of* nearly £1400. The investment account stood at £10,407 7*s*. 11*d*. and the trust fund £4917 2*s*. 3*d*., making a total of £15,324 10*s*. 2*d*. During the year ten candidates having passed the examination were admitted Fellows, 55 received the Diplomas in Surgery and Midwifery, 24 the Conjoint Diploma in Public Health, 8 the Licence in Dental Surgery, and 43 passed the preliminary entrance examination. There are at present living 435 Fellows, 2834 Licentiates, 181 Diplomates in Public Health, and 515 Licentiates in Dental Surgery.—At a meeting of the Fellows held on June 6th the following were *elected* office-bearers :—President : Mr. Arthur Chance. Vice-President: Mr. Henry R. Swanzy. Secretary of the College: Sir Charles A. Cameron, C.B. Council: Dr. Edward Hallaran Bennett, Mr. William Stoker, Sir Charles Cameron, Mr. John B. Story, Sir

William Thomson, C.B., Sir Charles B. Ball, Sir Thomas Myles, Mr. John Lentaigne, Dr. Richard D. Purefoy, Sir Lambert H. Ormsby, Mr. Henry G. Sherlock, Dr. R. Bolton McCausland, Mr. John S. McArdle, Mr. Robert H. Woods, Dr. Thomas Donnelly, Mr. William Taylor, Dr. Edward H. Taylor, Mr. G. Jameson Johnston, and Mr. R. Charles Maunsell.

ISOLATION HOSPITAL FOR TEIGNMOUTH.—A Local Government Board inquiry was held at Teignmouth (Devon) on June 2nd into the application of the urban district council for sanction to borrow £7100. £2471 are required for the erection of an isolation hospital and the remaining sum for the purchase of a recreation ground and other improvements.

UNIVERSITY OF OXFORD.—Dr. Joseph Frank Payne has been re-elected a representative of the University upon the General Medical Council.—Sir Arthur V. Macan has been appointed an examiner in midwifery, Dr. William Williams has been appointed an examiner in preventive medicine, and Dr. Marcus Seymour Pembrey has been appointed to examine in physiology in the first B.M. examination *pro hac vice*.

ROYAL INSTITUTION.—At a general monthly meeting of the members of the Royal Institution held on June 6th the sincere thanks of the members were returned to Mr. Andrew Carnegie for his donation of £1200 to enable Professor Dewar and Mr. R. A. Hadfield to prosecute their joint investigation on the physical properties of steel and other alloys at low temperatures, and to Dr. Frank McClean for his donation of £100 to the research fund of the Royal Institution.

UNIVERSITY OF CAMBRIDGE.—The degree of Master of Surgery has been conferred on Professor Howard Marsh, M.A.—The following have been appointed examiners for the final M.B. examinations in the next academical year: —Medicine: Dr. L. Humphry, Dr. S. West, Dr. W. Hale White, and Dr. J. Rose Bradford. Midwifery: Dr. M. Handfield-Jones and Dr. G. E Herman. Surgery: Mr. C. T. Dent, Mr. E. Owen, Mr. C. W. Mansell Moullin, and Sir Hector C. Cameron.—Dr. Ole Bull of Christiania has presented to the University two valuable portfolios of drawings illustrating the diseases of the eye and of the ear. Professor T. Clifford Allbutt has received permission to exhibit the drawings at Oxford during the approaching meeting of the British Medical Association.

LITERARY INTELLIGENCE.—Messrs. J. and A. Churchill will shortly publish a new work by Dr. J. C. Thresh entitled "The Examination of Waters and Water Supplies." The author says in his preface: "The microscopical and biological examination of matters suspended in drinking water has never received in this country the attention it deserves. Very often such an examination reveals more quickly and certainly the character of a water and some defects in its source than either a chemical or bacteriological analysis. In several instances such an examination has led, in my practice, to the discovery of sources of pollution which had been overlooked at a careful inspection. I have endeavoured therefore in this book to give it the importance it deserves." The importance of the systematic inspection of all sources of water supply is now fully recognised by the Local Government Board, so much so that the Commission on Sewage Disposal has expressed the opinion that Rivers Boards should be formed throughout the country.

EDINBURGH ROYAL INFIRMARY: A QUARTER'S DEFICIT.—The quarterly statement of the ordinary income and expenditure of the Edinburgh Royal Infirmary shows a deficit of £5295 The statement is drawn up by Mr. Patrick Blair, W.S., the convener of the house committee, who is a master of finance. During the quarter the daily average number of people under the roof of the infirmary was 1157, of whom 821 were patients. Compared with the corresponding quarter of the previous year the average daily number of patients was 69 more. There had been a marked diminution in the sums received from various sources. Taking all the sources together, both of ordinary and extraordinary revenue, the infirmary had received £7226, while for the corresponding period last year £8905 had been received. The expenditure for the period under review was £12,521. The increase in the cost of maintenance was only £264, although the increase in the daily average number of patients had increased above stated. It is probable that the deficit is not quite bad as it looks, for the works department expenses give item of £2485 for the quarter which might be include under extraordinary expenditure. The convener evident preferred to place it under ordinary expenditure and on t basis of the large deficit to point out to the board and to t public that £1000 a week is the rough sum required to r this important institution.

DEATH OF A CENTENARIAN.—There has just die at Flax Bourton workhouse, near Bristol, an inmate name Robert Lock who had reached his 104th year.

WATER-SUPPLY OF LYNTON AND LYNMOUTH.—Sir George Newnes formally opened the new water-supp for Lynton and Lynmouth on May 28th. The water brought from West Lyn, about one and a half miles fro Lynton. The polarite system of filtration is used. The co of the undertaking has been about £2500.

DONATIONS AND BEQUESTS.—Under the will Miss Esther Steel the Western Ophthalmic Hospita Marylebone-road, London, W., has been bequeathed the su of £1000.—Mrs. E. A. Williams has by her will bequeathe £500 to the Cancer Hospital, Fulham-road, S.W; £2 each to the London Hospital and the *Poplar Hospital f* Accidents; and £100 to the Victoria Cottage Hospital Romford.

INCORPORATED MEDICAL PRACTITIONERS' ASSOCIATION.—The thirteenth annual general meeting of th association was held at the Holborn Restaurant June 2nd, the retiring President, Mr. G. H. Broadbent (Manchester), being in the chair. On the proposition of M Joseph Smith, seconded by Mr. George Brown, Mr. Robe Ambrose, B.A., M.P., was unanimously elected President f the ensuing 12 months. Mr. F. Greaves and Mr. G. Brow were re-elected honorary treasurer and hononary secreta respectively. At the conclusion of the meeting the membe and their friends, to the number of about 40, dine together, the newly elected president, Mr. Ambrose, being the chair. In responding to the toast, "Prosperity to t Association and to the *General Practitioner*" (the offic journal of the association), proposed by Mr. Broadbent, M Ambrose said that since the society was established in 189 it had been a great success and had done much to uphol the status of the profession. The main object of t association was to safeguard the interests of the medic profession, especially those of the general practitioner, an this he claimed they had done more efficiently than an other society. One of their aims was to protect general practitioners from unfounded charges and the association had bee so prosperous during the past year that he hoped they woul shortly be able to establish a scheme of medical defence f the members at a cost much below the subscription charge by any other existing society. Their association, moreove provided a bond of mutual goodwill and fraternity betwee the members to promote which was an important part their good work. The influence of the association had bee shown by the fact that chiefly through their efforts, as h claimed, two of their members, general practitioners, ha been elected as Direct Representatives for England an Wales on the General Medical Council in place of two consultants who occupied the seats when the association wa first established. He thanked those present for their heart reception of the toast and he trusted that his year of offic would, as regarded the association, be one of increase prosperity and usefulness.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Medical Inspection of Schools.

THE Secretary for Scotland has received a memorial from the Roy College of Physicians of Edinburgh on the subject of the Scotch Education Bill and its bearing on the health of school children. Whil approving of the provisions dealing with medical inspection an physical training the memorialists point out that medical inspection o schools to be effective implies the power of the medical inspector t examine into the health of children and their capacity for mental an physical education as well as into the school hygiene in a broa sense. In many of the city schools it is contended that physica education is urgently needed and that it should be placed on scientific basis. Another point urged is that school boards should have the power to insure suitable feeding for the poorer classes of school children who cannot otherwise obtain proper nourishment. It will be recollected that Mr. Claude Hay brought this latter matter before the House of Commons with much force some time ago.

THURSDAY, JUNE 2ND.

Care of Pauper Children.

the place was certified for or of leaving some children in the workhouses. Provided there was no serious overcrowding Mr. Long considered that the former alternative was infinitely preferable. With regard to the abandonment of the practice of insisting on a probationary period for the children the department disapproved of the change of policy, but the managers had strong views on the subject and in this experiment they had behind them the opinion of their medical officer. In no single case could it be shown in his belief that the department had sanctioned an extension of the large barrack school system except such an extension as was necessary for the improvement of the existing accommodation.

Hospitals for Consumptives.

In the course of the same debate Mr. LONG made a passing reference to hospitals for consumptives. He stated that he believed the hospital at Skipton and the hospital provided by the joint unions of Liverpool had done very good work. The department would be glad to do anything it could to help the guardians in work of this character.

Adulteration of Milk.

Mr. KEARLEY dealt with the adulteration of milk when the Local Government Board vote was before the House. He asserted that the percentage of the adulteration of milk at the present time was 11 6 The percentage for the 25 towns which came next in order of size to London was 10 3,

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to The Lancet *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

Adeney, G. C., M.R.C.S., L.R.C.P. Lond., has been appointed Resident House Physician to St. Thomas's Hospital.

Bennett, H. S., M.R.C S., L.R C.P. Lond., has been appointed House Surgeon to Out-patients at St. Thomas's Hospital.

Birks, G. T., M.B., B.C. Cantab , has been appointed House Surgeon to Out-patients at St. Thomas's Hospital.

Birt, A. C., M.R.C.S., L.R C.P. Lond., has been appointed House Surgeon to Out-patients at St. Thomas's Hospital.

Carver, N. C., B.C. Cantab., has been appointed House Surgeon to Out-patients at St. Thomas's Hospital.

Crichton, Harry, M.D.. B.S. Durh., has been appointed Assistant Surgeon to the Infirmary, South Shields.

Davies, H. E., L.R.C.P. Lond., M.R.C.S., has been appointed Certifying Surgeon under the Factory Act for the Lutterworth District of the county of Leicester.

Evans, R. D., M.R.C.P. Edin., L.S.A., J.P., has been appointed Medical Officer to the Blaenau Festiniog Postal District.

Guthrie, T., M.B., B.C Cantab., M.R.C.S., L.R.C.P. Lond., has been appointed Resident House Surgeon to St. Thomas's Hospital.

Feldman, W. M., M.R.C.S., L R.C.P., has been appointed Surgeon to ss. *Merion* (American Line).

Harnett, W. L., M.B., B.C. Cantab., has been appointed Resident House Surgeon to St. Thomas's Hospital.

Haward, W., M.B., B.S. Durh., M.R.C.S., L.R.C.P. Lond., has been appointed House Physician to Out-patients at St. Thomas's Hospital.

Hedley, J. P., M.B., B.C. Cantab., has been appointment Junior Obstetric House Physician at St. Thomas's Hospital.

Higham, B., M.R C.S., L.R.C.P. Lond., has been appointed House Physician to Out-patients at St. Thomas's Hospital.

Hunter, James H., M.D., B.S., B.Hy. Durh., has been appointed Assistant Surgeon to the Infirmary, South Shields.

Ibbotson, W., M.R.C.S., L.R.C.P. Lond., has been appointed House Officer to the Throat and Ear Departments at St. Thomas's Hospital.

Latham, O. H., M.R.C.S., L.R.C.P. Lond., has been appointed Resident House Physician to St. Thomas's Hospital.

Lecky, H. O., M.B., B.Ch. Oxon., has been appointed Resident House Physician to St. Thomas's Hospital.

Lindsey, Eric C , M.R.C.S., L.R.C.P. Lond., has been appointed House Surgeon to the General Hospital, Hereford.

Macdonald, John, M.B., C.M. Edin., has been appointed Assistant Surgeon to the Infirmary, South Shields.

Pinches, H. I., M.B., B.C. Cantab., has been appointed Resident House Surgeon to St. Thomas's Hospital.

Rickett, G. R., B.C. Cantab., has been appointed House Officer to the Throat and Skin Departments at St. Thomas's Hospital.

Ross, E. A., M.B., B.C. Cantab., has been appointed Resident House Physician to St. Thomas's Hospital.

Sears, C. N., M.B., B.S. Lond., has been appointed Senior Obstetric House Physician at St. Thomas's Hospital.

Smyth, J., M.B., C.M. Glasg , has been appointed Clinical Assistant to the Chelsea Hospital for Women.

Thorne, J. M., M.R.C.S., L.R.C.P. Lond., has been appointed Clinical Assistant to the Chelsea Hospital for Women.

Wigram, L. E., M.B., B.C. Cantab., has been appointed Resident House Surgeon to St. Thomas's Hospital.

MINERS' PHTHISIS.

IN THE LANCET of May 21st, p. 1444, we referred to the exceptional prevalence of miners' phthisis among the men engaged in rock drilling. A leading article in the *Mining Journal* of May 28th discusses the same subject and calls for the issue of further regulations for the protection of the men employed in this particular work. In support of this contention the editor quotes a variety of statistics from the report of the Transvaal Commission which appeared last August and also from a paper very recently read before the Institution of Mining and Metallurgy by Dr. John S. Haldane and Mr. R. Arthur Thomas, manager of Dolcoath mine in Cornwall. Our contemporary concludes as follows:—

> The facts recorded by Dr. Haldane and his coadjutors show that [illegible] *Cornwall and South* [illegible] ner mining employ- [illegible] ed risk of occupation disease may be almost entirely eliminated by the use of water and that in quantities so slight as probably to cause but little danger of fostering ankylostomiasis, while in any case the use of salt should avoid this danger. It seems therefore imperative that in the case of South Africa, even more than in this country, the Government should *take steps to formulate rules forthwith to* protect the rock driller against his now declared enemy. Experience everywhere shows that it is futile to trust in any way to the sense of the men themselves, even where there is no pressure put upon them to hasten their work.

RICHARD COBDEN AND THOMAS WAKLEY.

To the Editors of THE LANCET.

SIRS,—In political circles the name of Richard Cobden has been in the ascendant for some time past and just now the minds of certain Englishmen are much set on celebrating the centenary of his birth. The moment appears opportune to recall a fact of some medical interest which is brought out in a letter written by Cobden in 1864—viz., that when hard work told upon him, to recuperate his health he was wont to act upon (in part at any rate) a wholesome hint which he had gained from his Parliamentary colleague and friend, Thomas Wakley. Writing to Mr. Henry Ashworth under date July 6th, 1864, Cobden says:—

> "It would have given me great enjoyment to have visited you at your Highland box, but I go quietly among my children at Dunford during the fine weather, for I always feel under the liability of being induced to leave home for a southern clime in the winter. During the Session I see little of my young people, and I really think it is as healthful as it is pleasant to relax after the turmoil of the House and the clubs among the minds of children. I remember hearing Wakley say in the House when O'Connell first showed symptoms of giving way that if he would withdraw from politics and live with his grandchildren he might last for 10 years. But he died in a twelvemonth."—Morley's "Life of Richard Cobden," vol. ii., p. 454 (London: Chapman and Hall, 1881).

In less than nine months after writing the letter from which the above is extracted Richard Cobden died. Thomas Wakley had predeceas [illegible] O'Connell had "gone over to the [illegible] Pre-eminent in their several spheres [illegible] or the common weal, unselfishly jeopardising health and strength, and probably length of days, for, to O'Connell only was it given to live out the "allotted span." Wakley took no holidays until his health was permanently ruined, although he did consent to cease from Parliamentary duties a few years before the end.

I am, Sirs, yours faithfully,
W. R.

June 1st, 1904.

CONSULTANTS AND LIFE ASSURANCE.

To the Editors of THE LANCET.

SIRS,—A. and B. were in partnership. The partnership has been dissolved. A. becomes a consultant in medicine and surgery. B. continues in general practice. Is A. as a consultant prevented from conducting examinations for life assurance?—I am, Sirs, yours faithfully,
C. D.

June 8th, 1904.

⁂ No.—ED. L.

NEW VIEWS ON CELLULAR PHYSIOLOGY.

A CORRESPONDENT has forwarded to us a circular which he received from a lady who has recently started an establishment for giving light baths to ladies only. The advertiser states that she has procured a bath which is "an exact copy of the one supplied to H.M. King Edward VII. at Buckingham Palace and Windsor Castle" and her knowledge of the effects of electricity upon the body may be gathered from the following delightful paragraph. "For obesity I give the *combined light treatment* (using Arc Lights as well as Incandescent) from two to four times a week for about 20 minutes. The rays of the *Arc Light* bring about the necessary transformation of superfluous fat into muscular substance by reason of the increased oxidation." Again we read: "Owing to the penetrating power of light rays much more is accomplished; the deeper tissues of the skin are excited to activity, the heat-making process, by which fat may be consumed, are (*sic*) stimulated to an unusual degree as shown by the increased elimination of carbon-dioxide." We have said enough to show that the advertiser is grossly ignorant of what she is talking about and we think that it is quite time that the uncontrolled use of such powerful forms of energy as electrically generated light and heat should be taken into consideration by the Government, so that legislation might be formulated to put a stop to what we cannot but stigmatise as dangerous quackery.

FEMALE NURSES AND MALE PATIENTS.

To the Editors of THE LANCET.

SIRS,—I should be glad of an expression of your opinion on the following facts. We have in this district (as in most other poor parts of London) nurses belonging to the Queen Victoria Jubilee Nursing Association placed here by that association under the direction of a local committee who pay all expenses. It is usual for the local medical men to requisition the services of these nurses for operations and in accordance with this custom I notified them on Sunday, June 5th, that I should require two nurses to attend for an operation at a patient's house at 1 P.M. on Monday. One nurse attended at said house early on Monday morning to prepare the patient and then discovered that the operation was for phimosis in a man about 23 years of age. At the time fixed for the operation the same nurse accompanied by her senior appeared, and before entering the room the latter requested to see me. I complied with her request, and to my astonishment I was asked by her in a most impertinent manner: "What operation is this you are about to perform?" I told her. She then in the same tone continued, "I am most surprised that you should ask us to attend for an operation of this nature in *a man*; you have no right to ask us to do such a thing, and it is no part of our duty to do so." I merely told them to leave the house and I would manage without them, which considering that I had to administer an anæsthetic and to operate unassisted was no easy task. What makes the situation still more absurd is the fact that a few weeks before these very same nurses were with me at an operation for fistula in ano in a man of 45 years, and dressed the case daily afterwards. They are middle-aged women engaged daily in the ordinary routine of their work in administering enemata and all other nurses' duties to males of all ages and are both certificated midwives. They have to-day told a member of the local committee that in no hospital in London would a nurse be allowed to be present at an operation on the sexual organs of a male. Will you kindly express your opinion on the matter, since in an experience of a quarter of a century I have never heard that a hospital trained nurse was not allowed or expected to be present or assist at operations of this nature or undertake the daily dressing of such cases.

I am, Sirs, yours faithfully,

Silvertown, E., June 6th, 1904. JAMES MACDONAGH.

⁂ A hospital nurse attends such cases as she is instructed to attend, regardless of such points as are alluded to in our correspondent's letter.—ED. L.

A CASE FOR DIAGNOSIS.

To the Editors of THE LANCET.

SIRS,—I send you a copy of the contents of a letter received from a country patient yesterday. I had to make a diagnosis and formulate treatment upon the facts therein contained. Perhaps it may serve to exercise the ingenuity of those younger practitioners who pride themselves upon making correct diagnosis by intuition. The letter is as follows:—

May 8th, 1904.

MR. ——,—Come from my bellie till in my head and I cant speak and my ears are swell. (Signature) ——.

Perhaps, Sirs, you will be good enough to favour me with your view of the case. I diagnosed quinsy.

I am, Sirs, yours faithfully,

Knysna, Cape Colony, May 9th, 1904. WALTER H. HAW.

TETANUS AFTER THE APPLICATION OF A SPIDER'S WEB.

SOME days ago in Dgitomir, Russia, a boy cut his leg with a piece of glass and in order to stop the bleeding a spider's web was applied, taken from a corner in a shed. About ten days afterwards when the lad appeared to be all right he was suddenly taken with spasms. On being seen by a medical man tetanus was diagnosed. His condition was declared hopeless and in the course of a few hours he died.

THE DECAY OF ILLUSTRATING.

To the Editors of THE LANCET.

SIRS,—Many of the diagrams to be found in our modern medical books and periodicals leave much to be desired. If they are compared with those of earlier treatises it will be readily conceded that want of care and precision are prominent features of latter-day diagrammatic representation. A bad photograph is sometimes excusable, but it is difficult to tolerate faulty pen-and-ink work. So often do we see now a quill-sketched diagram with shading in the wrong place, furrows for ridges or *vice versâ*, and other unacceptable anomalies. There are few more perfect diagrams than those in Wilson's Anatomy published about 35 years ago, but this only represents a type of illustration common at that time. There can be no method more graphic than drawing in simple outline and it is a matter for regret that this style is not more frequently had recourse to by amateurs who often aim too high. No criticism is inferred in respect of professional artistic work, which usually effects all that can be desired.

I am, Sirs, yours faithfully,

May 30th, 1904. H. P. P.

PHOTOGRAPHS OF RIFLE SHOTS.

Messrs. Thomas Christy and Co. of 4, 10, and 12, Old Swan lane, Upper Thames-street, E.C., have sent us a reproduction from a photograph of a rifle shot travelling at the rate of 30,000 feet per second, which is a very remarkable illustration of the high pitch of efficiency to which instantaneous photography has reached. The reproduction shows clearly the manner in which the bullet rends the air asunder into waves in its exceedingly rapid progress. The air waves vary in shape according to the shape of the bullet. The photograph was taken on a Dr. Schleussner's "special rapid observatory plate" and the exposure was one-millionth part of a second by means of the electric spark. Specially rapid plates are also made for rapid orthochromatic work, without a screen, for observatory work, stellar photography, and micro-photography.

◆

J. H. J.—There is no certain deterrent of mosquitoes and the like pests applicable for daily and general use. An ointment containing turpentine has been used with success, as also the essential oil of pennyroyal—not mentha pulegium but hedeoma pulegioides.

W. R.—We cannot give an answer to our correspondent solely on the facts before us. Appointments are not necessarily transferable with a practice and C. may justifiably have sought to gain the appointments for himself.

H. R. H.—Our attention has already been drawn to the handbill in question and we expressed our opinion in THE LANCET of June 4th that the name of the practitioner should not have been inserted.

J. A. G.—The conditions mentioned would support a diagnosis of drunkenness.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (13th).—London (2 P.M.), St. Bartholomew's (1.30 P.M., St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9 30 A.M.), Royal Free (2 P.M.), Guy's (1.30 P.M.).

TUESDAY (14th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Royal Ear (3 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Soho-square (2 P.M.), Chelsea (2 P.M.).

WEDNESDAY (15th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic, 1 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Gt. Ormond-street (9.30 A.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9 30 A.M.), Cancer (2 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.).

THURSDAY (16th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho square (2 P.M.), North-West London (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), St. Mark's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.).

FRIDAY (17th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), City Orthopædic (2.30 P.M.), Soho-square (2 P.M.).

SATURDAY (18th).—Royal Free (9 A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing Cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

TUESDAY (14th).—ROYAL MEDICAL AND CHIRURGICAL SOCIETY (20, Hanover-square, W.).—8.30 P.M. Paper:—Dr. A Newsholme; Protracted and Recrudescent Infection in Diphtheria and Scarlet Fever.

MEDICO LEGAL SOCIETY (20, Hanover-square, W.).—8.15 P.M. Papers:—Mr. R. H. Wellington: "Suicide whilst Temporarily Insane" a Fallacy.—Dr. W. McCallin: A Note on Legal Procedure in Lunacy.—Earl Russell: The Limitations of Medical Evidence.

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

Will Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them! Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, MR. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

The Milroy Lectures

ON

DEATHS IN CHILDBED: A PREVENTABLE MORTALITY.

Delivered before the Royal College of Physicians of London on Feb. 25th and March 1st and 3rd, 1904,

By W. WILLIAMS, M.A., M.D., D.P.H. Oxon.,
MEDICAL OFFICER OF HEALTH TO THE GLAMORGAN COUNTY COUNCIL.

LECTURE I.

Delivered on Feb. 25th.

Mr. President and Gentlemen,—My first duty is to thank the Council of the College for having conferred upon me the honour of electing me to deliver the Milroy lectures for the year.

In my capacity as medical officer of health, at first in an agricultural area and afterwards in a mining and industrial county, it has been my duty to investigate on several occasions the epidemic prevalence of puerperal fever. As some of the conclusions arrived at during the earlier years of my investigation seemed startling I have been led to extend it and to include the causes of death that are incidental to childbirth. By studying the circumstances which are injurious or fatal to parturient women one may justly hope to contribute to some extent to removal of the evils which shorten their lives and to the improvement of the race generally. I have selected as my subject "Deaths in Childbed: a Preventable Mortality," for the following amongst other reasons: 1. It is a dark, deep, and continuous stream of mortality which has been running through our statistics since the commencement of registration—indeed, from the most remote periods—without showing any signs of abatement and occasionally overflowing its banks, producing epidemics with most disastrous results. 2. It is a mortality which is to a great extent preventable, as evidenced in the enormous improvement which has of late years marked the records of lying-in institutions generally and under conditions where precautionary measures are strictly observed. *Then, if preventable, why not prevented?* 3. It is a mortality which has been exceptionally high among the women of Wales, in whose health and safety I am greatly interested, and with the mode of life, social relations, and conditions of the existence of whom I am fairly well acquainted. 4. It is high time that some serious attempt should be made by the legislature, the medical profession, and all concerned to put an end to such a painful sacrifice of mothers which stealthily but surely takes place annually. 5. It is a subject closely associated with preventive medicine and which equally concerns the general practitioner and the medical officer of health. I have marshalled at some trouble a formidable array of figures and facts which cannot fail to convince the most callous that it is our duty to use all endeavours to protect the valuable lives of the mothers of England and Wales, over 4000 of whom die annually in childbirth, about half of that number falling a prey to the ravages of puerperal fever which is, to a very great extent at least, a preventable disease. I wish I could designate it as an absolutely preventable disease. Some have done so, yet occasionally a few cases do occur which are difficult to trace to any definite source of infection.

What are the causes of death in childbed? These have been classified by the Registrar-General and others into two groups—(1) puerperal septic diseases and (2) accidents of childbirth—and I propose to adhere to this method. The terms "metria" and "puerperal fever," formerly employed to designate cases of death belonging to the first group, are no longer to be used. Phlegmasia alba dolens, an obviously infectious disease, was up to 1900 included in the tables with diseases of parturition. In the new tables issued by the Local Government Board and the schedules of the causes of death issued in 1901 by the Incorporated Society of Medical Officers of Health the term "puerperal fever" is to include pyæmia, septicæmia, sapræmia, pelvic peritonitis, and peri- and endo-metritis occurring in the puerperium. Under "accidents of childbirth" are included: abortion, miscarriage, puerperal mania, puerperal convulsions (including puerperal nephritis and puerperal uræmia), placenta prævia, flooding and accidental hæmorrhage, and other accidents of pregnancy and childbirth (to include puerperal thrombosis and embolism, sudden death, extra-uterine pregnancies, obstetrical operations, and retained placenta). It is with these causes of death in childbirth that I am mostly concerned. There are reasons to doubt, however, whether the returns with respect to deaths incidental to parturition are yet complete.

Childbirth and childbed.—Whenever parturition or miscarriage has occurred within one month before the death of the patient the Registrar General requires that the fact shall be certified even though childbirth may not have contributed to the fatal issue. By childbed is meant that period of a woman's life during and immediately following the act of parturition and during which women are especially liable to various diseases peculiar or incidental to childbirth. Its length varies in different cases from a few weeks to a few months or longer and is determined in ordinary circumstances by (1) the physical condition and health of the parturient woman; and (2) the care, skill, and attention extended to her during labour. There are many other diseases known which terminate fatally or are accelerated by childbirth and these may be divided into pre-existing diseases and acute diseases. The most common pre-existing diseases of long standing that terminate fatally in childbed are (according to the Registrar-General), in the order of their fatality: chronic Bright's disease, phthisis, syncope (weak heart), bronchitis, valvular disease, and anæmia. The most common acute diseases ending fatally in childbed are pneumonia, acute nephritis, influenza, acute bronchitis, scarlet fever, diphtheria, enteric fever, &c. I do not propose on this occasion to deal with these, except in so far as scarlet fever, diphtheria, and enteric fever sometimes complicate the process of childbirth. I propose to deal with the subject under the following subheadings: 1. The causes of deaths in childbirth. 2. The incidence of mortality in childbirth in (*a*) England and Wales 1847-91 (55 years) and from 1881 to 1900 (20 years); (*b*) the registration counties of England and Wales from 1848 to 1891 (54 years), and from 1881 to 1900 (20 years); (*c*) the registration counties of Wales, especially Glamorgan, Monmouth, and Salop; and (*d*) some large towns, industrial and mining centres. 3. The analysis of the causes of this mortality. 4. The mortality statistics of some maternity hospitals. 5. The etiology of puerperal fever. 6. The prevalence of epidemics of puerperal fever personally investigated and recorded by others. 7. The way in which women, especially of the poorer classes, are attended during labour. 8. The movement for insuring better training, registration, &c., of midwives. 9. The Midwives Act, 1902: (*a*) an epitome of it; (*b*) Central Midwives Board, its establishment, *personnel*, duties, regulations and suggestions just issued; and (*c*) the administration of the Act and other preventive measures. In other words, I propose to deal with the subject in its statistical, etiological, and preventive aspects. I also intend to endeavour to prove by means of statistics fairly handled and extending over considerable periods and having reference to a large number of births that the mortality in childbirth has remained undiminished, that puerperal septic diseases are to a very great extent preventable, that deaths from "accidents of childbirth" are controllable or to a considerable extent preventable, and to point out the means whereby these ends may be secured.

Puerperal septic diseases.—In the earlier reports the term "metria" is made use of up to 1850 and for many years after that date. The term "puerperal fever" was made use of for the first time in 1850 and it is often continued up to the present, but in a circular letter to medical practitioners by Dr. John Tatham they are advised to abandon it altogether. The separate forms of septic infection given in the "new list of causes of deaths as used in the annual reports of the Registrar-General of England and Wales" are puerperal septicæmia, puerperal septic intoxication, puerperal pyæmia, phlegmasia alba dolens, puerperal fever (not otherwise defined), or puerperal septic diseases. Although the exact nature of the morbid conditions thus designated is even now a subject of controversy, yet the fever with symptoms of acute and general blood poisoning to which women in childbirth are peculiarly liable has symptoms of a sufficiently definite character, such as high temperature, quick pulse, furred tongue, fœtid or suppressed lochia and milk, &c., to admit of its classification under this heading and clear differentiation from any other causes of death in childbirth.

Accidents of childbirth.—Under this heading are contained deaths from "the various mishaps of childbirth," some of which will always be inevitable but a considerable proportion of which prove fatal in the absence of proper obstetric assistance and skill.

Table I. gives statistical information in regard to the mortality in childbirth in England and Wales for a period of 55 years (1847 to 1901) and contains the latest obtainable figures. The death-rates are based on the proportion of deaths to registered births and not on the population, as in corresponding rates for other diseases. We have in this method a more accurate gauge of the amount of the mortality, which if not absolutely correct is more nearly so than any calculation based upon an always variable population. Of course, miscarriages and stillbirths are not included, as the law does not compel the registration of these births known as stillbirths, so that the mortality in childbirth following such births is not included. Dr. J. R. Kaye in a paper entitled "Certification and Registration of Deaths—the Urgent Need for Improvement," which appeared in the *Journal of State Medicine* for June, 1902, wrote:—

> *Stillbirths.*—One of the most glaring and most dangerous defects of our Registration Acts, and the most loudly calling for reform, is the omission to compel the registration of those officially known as stillbirths. Can anything be more extraordinary than that, in this educated twentieth century, any woman, no matter her character, if she elects to call herself a midwife, is at liberty to issue a certificate for the burial of children who are born still or otherwise on her undefined certificate? Why should our maternal mortality records (imperfect though they be), upon which so much time and labour has been expended, be impaired, and why should the *compulsory contribution* (the death certificate) of the registered medical practitioner be further degraded by the acceptance of worthless information from unqualified sources?

What do Tables I. and II. prove? They do not prove very much. They show that the mortality from puerperal septic diseases reached its maximum point during registration times in 1874 when it was 3·63 per 1000; the year 1893 comes next with 3 30 per 1000 From 1874 and 1875 to 1881 the mortality was again much the same as it was before 1874. In 1881, 1882, and 1883 the mortality rate increased considerably, and this increase has continued to the present time, and was particularly high in 1892, 1893, and 1894. As far as accidents of childbirth are concerned, the mortality-rate varied from the highest in 1847 (4·5 per 1000) to the lowest in 1886, 1887, and 1889 (1·9 per 1000). Indeed, since 1874 (3·30 per 1000) there has been little or no decrease in the death-rate. It will be remembered that the year 1893 was exceptionally dry and that the mortality from enteric fever and diarrhœa was higher than in any previous year since 1884 Immediately before 1874 the death-rate from puerperal septic diseases was not particularly high, but from 1881 to 1900—a period of 20 years—there has been a higher sustained mortality than in any previous and corresponding period. During the years in question it was highest in 1893 (3·30 per 1000), the year immediately preceding the most severe outbreaks of influenza. It was lowest in 1898 (1·84 per 1000). It was not until the Public Health Act of 1872 (decreeing the appointment of medical officers of health) became generally adopted that certification of the causes of deaths by medical men was turned to scientific account, but the Registrar-General has issued most valuable reports since 1839 and it is to these reports that we are indebted for the "sheet-anchor of the public health service," the Public Health Act of 1875.

In 1874 the Registration Act was placed upon the statute book which made it incumbent on medical men to furnish certificates of the causes of deaths of all patients who died whilst attended by them. The Registrar-General in his thirty-eighth annual report for the year 1875 writes:—

> The mortality of the mothers of England and Wales, notwithstanding the progress of the obstetrical art, was higher in 1874–75 than it has been since 1847.

It was about 1874, in consequence of the Public Health Act of 1872, that it became incumbent upon local authorities in all parts of England and Wales outside the metropolis to appoint medical officers of health and it was then for the first time that the greater number of rural districts at least came under medical supervision.

The rise in the mortality from puerperal septic diseases which began after 1881 may be partly explained by the fact that it was in 1881 that the Registrar-General for the first time (with a view of making the returns of deaths in childbirth more complete in cases where the certificates of deaths

were not satisfactorily filled up) commenced the practice of sending out letters of inquiries to all practitioners who had used the terms "peritonitis," "pyæmia," "septicæmia," &c., in registering the deaths of women of the child-bearing age. It is certain that such a practice (which has been continued up to the present time) has led to the inclusion under the heading of "puerperal fever" of a number of deaths that would otherwise not have been classified as such, and doubtless the increased mortality *from* this cause is more apparent than real. I am perfectly willing to make full allowance for this and to concede that the sustained increase of the mortality in childbirth, especially puerperal fever (puerperal septic diseases) during the last 20 years may be at least partly accounted for in this way. When this is granted we are still face to face with the fact that the childbirth mortality has not at all diminished in the past 20 years; on the contrary it will be noticed in glancing over the above tables that this mortality for the years 1892, 1893, *and* 1894 *was* 5·78, 6·51, *and* 5·36 *per* 1000 *respectively*, and that 6·51 per 1000, the rate for 1893, is the highest on record since the commencement of a system of registration. Moreover, the mortality rates per 1000 from puerperal fever and accidents of childbirth for these years are correspondingly high, viz. :—

	1892.	1893.	1894.
Mortality in childbirth	5·78	6·51	5·36
Puerperal fever	2·62	3·30	2·43
Accidents, &c.	3·16	3·19	2·92

Therefore it will be seen that the mortality in both groups has remained undiminished up to the present. How can this anomaly be explained in view of the enormous advances made in surgery, of the adoption of aseptic and antiseptic precautions in normal midwifery practice, of the reduction of mortality in childbirth that has occurred in the case of lying-in hospitals and under other conditions, and of the improvements in sanitary conditions generally that have taken place during this period? There is only one way of possibly explaining this increase and if we are justified in answering (though on this point I have no information) that some of the amended death certificates sent in response to the circulars of the Registrar-General would otherwise have altogether escaped registration under the heading of childbirth, we are also justified in believing that the general death-rate of childbed mortality, apparently stationary, or very nearly so, for the last 40 years, has in reality declined somewhat and "that in spite of what I fear must be admitted—viz., that the advance of civilisation does not at all tend to decrease the perils incidental to the physiological function of childbirth." There is, however, no getting away from the [illegible] years, when a more accurate [illegible] upwards of 40 per cent. of the [illegible] been caused by septic diseases. *It will further be seen that this undiminished mortality has* been sustained for a period of 20 years and that the sources of fallacy are not confined to one or to a few years. It will be noticed also that this period (1881-1900) of undiminished mortality in childbirth coincides with a period in which enormous strides have been made in all matters pertaining to sanitation generally and with a period of improved certification of the causes of death in connexion with childbirth. It is highly probable, therefore, that this undiminished mortality is the direct result of the improved certification and that it is more apparent than real. It has been proved without a doubt that during recent years the mortality in lying-in institutions generally—both in their internal and external departments—has also decreased to the vanishing point, so that we are forced to the conclusion that this undiminished and sustained mortality takes place outside *maternity hospitals—i.e., in general practice*—and that the conditions under which women are confined outside of these institutions have not shared to an equal degree the improvements effected in their internal and external departments.

XII. Welsh—		
Monmouthshire	2·0	3·6
South Wales	2·2	3·7
North Wales	2·1	2·2

Before proceeding to investigate the causes at work in sustaining this persistently high mortality it would be useful to consider its geographical distribution. The various registration counties in England and Wales present marked differences in reference to death-rate from childbed mortality and I have therefore decided to consider each registration county on its own merits (Table III.); on a former occasion I have worked out the statistics from 1848 to 1894, and for the purposes of these lectures I have done so up to 1901.

The foregoing figures show that the death-rate from puerperal septic diseases (per 1000 registered births) ranges from 2·3 to 1·2 in the various counties thus:—

TABLE IV.—*Death-rate from Puerperal Septic Diseases in Registration Counties.*

Lancashire	2·3	Surrey	1·9	Oxfordshire... ...	1·6
Cheshire	2·2	Middlesex		Devon	
Northumberland		Northants		Somerset	
South Wales ...		Norfolk		Kent	
London	2·1	Worcestershire ...		Bucks	1·5
Derbyshire		Notts		Cambridgeshire...	
West Riding ...		Gloucestershire ...	1·8	Essex	
Durham		Herefordshire ...		Lincolnshire ...	
Cumberland ...		North Riding ...		Suffolk	1·4
North Wales ...		Westmorland ...		Sussex	1·3
Salop	2·0	Hants	1·7	Hunts	
Staffordshire ...		Berks		Dorset	
Monmouthshire		Herts		Rutland	
		Bedfordshire ...		Cornwall	1·2
		Wilts			
		Warwickshire ...			
		Leicestershire ...			
		East Riding... ...			

The mean death-rate per 1000 for England and Wales is 1·8. Lancashire heads the list with 2·3 and is closely followed by Cheshire, Northumberland, and South Wales with 2·2; London, Derbyshire, West Riding, Cumberland, and North Wales with 2·1; Salop, Staffordshire, and Monmouthshire, with 2·0; Surrey, Middlesex, Northants, Norfolk, Worcestershire, and Notts with 1·9, all of which are above the mean for England and Wales (1·8). Cornwall has the lowest rate—1·2 per 1000—and Sussex, Hunts, Dorset, and Rutland come next with 1·3; Suffolk has 1·4; Bucks, Cambridgeshire, and Essex have 1·5; Kent, Oxfordshire, Devon, and Somerset, 1·6; and Hants, Berks, Herts, Bedfordshire, Wilts, Warwickshire, Leicestershire, and East Riding, 1·7.

That there is a marked difference in the various rates is obvious, but we are not justified at this stage in drawing any conclusion from the figures before us, for even the circumstances which obtain in various localities only a few miles apart in the same county are vastly different, as I hope to prove later. However, as a general rule it would seem that the rate was highest in the western counties, especially in the hilly districts, or roughly in those counties west of a line drawn from the mouth of the Severn to that of the Tees.

The death-rate from accidents of childbirth ranges from 3·7 to 1·9 per 1000 registered births, thus:—

TABLE V.—*Death rate from Accidents of Childbirth in Registration Counties*

South Wales ...	3·7	Berks	2·8	Northants	2 5
Monmouthshire...	3·6	Dorset		East Riding... ...	
Herefordshire ...	3·3	Herts	2·7	Cambridgeshire...	2·4
Cheshire	3·2	Oxfordshire... ...		Suffolk	
Lancashire	3·1	Bedfordshire ...		Warwickshire ...	
Wilts	3·1	Somerset		Leicestershire ...	
Cornwall		Gloucestershire...		London...	2·3
Salop		Lincolnshire ...		Kent	
Derbyshire		Norfolk...		Hunts	
North Riding ...	3·0	Sussex	2 6	Essex	
Bucks	2·9	Surrey		North Wales ...	2·2
West Riding ...		Hants		Rutland	1·9
Durham		Middlesex			
Northumberland		Devon			
Cumberland ...		Staffordshire ...			
		Worcestershire ...			
		Notts			
		Westmorland ...			

In these statistics a much wider difference between the two extremes is observed and the death-rate is above the mean for England and Wales (2·7 per 1000) in Berks, Bucks, Wilts, Dorset, Cornwall, Herefordshire, Salop, Derbyshire, Cheshire, Lancashire, West Riding, North Riding, Durham, Northumberland, Cumberland, Monmouthshire, and South Wales. It is below the average in London, Surrey, Kent, Sussex, Hants, Middlesex, Northants, Cambridgeshire, Norfolk, Hunts, Essex, Suffolk, Devon, Staffordshire, Worcestershire, Warwickshire, Leicestershire, Rutland, Notts, East Riding, Westmorland, and North Wales. It will be observed also on examining the figures of the various registration counties that they vary to a considerable extent and thus suggest that the extent and intensity of the causes at work are different at different times and that the accidents of childbirth are, at least to a certain extent, controllable. So far the figures do not prove much but they do show that the mortality from puerperal septic diseases is more evenly distributed than is the mortality from accidents of childbirth and that no diminution has occurred in either case. Both rates are similar in that they are highest in the Welsh and North-Western counties.

Having failed to arrive at any definite conclusion (except that the mortality under each subheading has remained undiminished) by studying the mortality in childbirth during a period of 54 years I now propose to confine my attention to the period of 20 years from 1881 to 1900. This period coincides with the time that has elapsed since the introduction of antiseptics into surgical work, with a period during which great advances have been made in sanitary matters, and with the more reliable certification of the causes of death. (Fig. 1.)

Before 1881 (when the circular letter to medical men already referred to was sent out by the Registrar-General for the first time) it is probable that many deaths in childbirth, especially from the puerperal septic diseases, escaped registration as such. In support of this statement I quote the words of the Registrar-General in his forty-seventh annual report:—

> Out of 453 cases of married women whose deaths were returned in 1884 simply as due to peritonitis or septicæmia, it was found on inquiry that no less than 156 were cases of a puerperal character.

So we may rightly assume that the figures given after 1881 are nearer the truth than are any that appeared before. During this period of 20 years I propose to deal with the mortality in childbirth in the various registration counties of England and Wales, in some large towns, industrial and mining centres, and in some country districts, and to examine more in detail the statistics for Wales, Monmouthshire, Herefordshire, and Salop, and still more in detail the statistics of the various registration divisions of the county of Glamorgan during the same period; for it appears more reasonable to endeavour to arrive at the truth by the method of reasoning from the general to the particular rather than the reverse.

An examination of the figures given below shows that the death-rate per 1000 registered births from puerperal septic diseases range from 3·0 to 1·4 in the various counties.

I Counties with rates above 25
II „ „ „ between 24 & 23 (both inclusive)
III „ „ „ „ 22 21
IV „ „ „ below 21
NORTHUMBERLAND
DURHAM
CUMBERLAND

The figures in Table VI show that the death-rate was highest in the Welsh, North-Western, Northern, and Yorkshire (West Riding) counties to the west of a line drawn from the mouth of the Tees to the estuary of the Severn. In the first 20 counties in the list the rates were above the average (2·1 per 1000) for England and Wales; in the next four counties they were the same as the mean rate; while in the remainder they were below that rate.

The death rate from accidents of childbirth ranges from 3·3 to 1·7 per 1000 registered births, as may be seen from Table V. (Fig. 2.)

The above figures tend to show that the rate is highest in the Welsh division, in Cornwall, and in all probability in the more agricultural districts of these counties, whereas the rates are lowest in London and in the counties immediately surrounding it.

I now come to consider the statistics of the Welsh counties together with Monmouthshire. I include the latter because one would naturally expect to have very similar figures for this county as for Glamorgan, for the physical and industrial conditions of its western valleys and in the more agricultural portions of the eastern part of it are almost identical with the conditions which obtain in the mining valleys and the agricultural Vale of Glamorgan respectively. I also include the county of Salop of which I have a fair personal knowledge, and although it may be considered as entirely an agricultural county and in this respect similar to several of the Welsh counties, yet its physical features are entirely different. The absence of any high mountains renders it entirely different from most of the agricultural counties of Wales, especially those that border upon it.

WALES, MONMOUTHSHIRE, AND SALOP.

Although the mortality-rates from both puerperal fever and accidents of childbirth seem to be excessively high in the North Wales and South Wales groups of counties yet it is quite possible that these rates are not high throughout the 12 constituent counties, and in order to arrive at the truth it is essential to give figures for each of these counties for the period 1881–1900, the same as has been done for each of the English counties, and unless this is done comparison is impossible. Indeed, it has always puzzled me to make out why it is tha[illegible] -General has never given the [illegible] promin[illegible] e Welsh counties in his valuable [illegible] orts as ha[illegible] to far less important and smaller [illegible] glish coun[illegible] [illegible] a f[illegible] of the general and local features [illegible] ch of th[illegible] together with Monmouthshire Salop, I [illegible] the figures for each of these [illegible] ies and [illegible] in [illegible] the various regis [illegible] district[illegible] of Glamorgan [illegible] view o[illegible] le on the con- of fema[illegible] ces which deter- [illegible] dif[illegible] pical example of [illegible] w[illegible] of its to-day [illegible] 30 to 40 years [illegible] th[illegible] and sparsely [illegible] un[illegible]

WALES.

The position of North Wales and South Wales as compared with England and Wales, from 1848–1900 and from 1890–1900, will be learnt from the following tables:—

TABLE VIII.—*Mortality in Wales compared with England and Wales.*

—	Deaths per 1000 for 53 years (1848–1900).			Deaths per 1000 for 20 years (1881–1900)		
	Puerperal septic diseases.	Accidents of childbirth.	Childbed (all causes).	Puerperal septic diseases.	Accidents of childbirth.	Childbed (all causes).
North Wales... ...	2·1	2·2	4·3	2·9	3·5	6·4
South Wales... ...	2·2	3·7	5·9	2·8	3·6	6·4
England and Wales	1·8	2·7	4·5	2·1	2·4	4·5

TABLE IX.—*The Comparative Number of Mothers Dying in Childbed for periods of 53 Years and 20 Years respectively.*

—	53 years (1848–1900).			20 years (1881–1900).		
	Puerperal septic diseases.	Accidents of childbirth.	Childbed (all causes).	Puerperal septic diseases.	Accidents of childbirth.	Childbed (all causes).
North Wales	1 in 476	1 in 454	1 in 232	1 in 344	1 in 285	1 in 156
South Wales	1 in 454	1 in 270	1 in 169	1 in 357	1 in 277	1 in 156
England and Wales	1 in 555	1 in 370	1 in 222	1 in 476	1 in 416	1 in 222

That is to say, there died annually from puerperal fever for the period of 53 years one out of 555 mothers confined in England and Wales as compared with one mother in every 476 in North Wales, and one in 454 in South Wales, whilst during the same period there died in England and Wales from the accidents of childbirth one in 370, as compared with one in 454 in North Wales and one in 270 in South Wales during the same period. Again, during 20 years 1881–1900 in England and Wales there died from puerperal fever one in every 476 women confined as compared with one in 344 in North Wales and one in 357 in South Wales, whilst during the same period there died in England and Wales from the accidents of childbirth one in 416, as compared with one in 285 in North Wales and one in 277 in South Wales. It will be further noticed that the mortality from puerperal septic diseases for both these periods is very much the same in the North Wales and the South Wales groups of counties, whereas the mortality from accidents of childbirth for the 53 years (1848–1900) is considerably higher in South Wales than in North Wales, or as 1·7 is to 1. Again, during the period of 20 years (1881–1900) the mortality from puerperal septic diseases is much the same in North Wales and South Wales, whereas the mortality from accidents of childbirth is only slightly higher in South Wales than in North Wales. Moreover, it will be seen that the mortality-rates from puerperal septic diseases and accidents of childbirth are respectively 1·8 and 2·7 for the 53 years and are 2·1 and 2·4 for the 20 years' period, so that the mortality-rate from puerperal septic diseases has increased from 1·8 to 2·1 per 1000 and the mortality rate from accidents of childbirth has diminished from 2·7 to 2·4 per 1000, thus making the total mortality-rate of 4·5 per 1000 the same for both periods.

The following table (Table X.) gives statistical information for each Welsh county for a period of 20 years (1881–1900).

The death-rate from puerperal septic diseases is excessively high in Merionethshire and Cardiganshire, two typical instances of purely agricultural and mountainous districts containing old-fashioned market towns, some fashionable seaside resorts, and the quarry districts of Festiniog and neighbourhood. Denbighshire, Glamorgan, Carnarvon, and Carmarthenshire come next; these may be described as scattered mining and hilly agricultural districts, the most typical mining county being Glamorgan. Brecknockshire,

A. = Puerperal septic diseases. B. = Accidents of childbirth.

Arranging the counties in the order of their death-rates, those with the highest coming first, we get the following results:—

TABLE XI.—*Counties arranged in Order of Death-rates.*

Puerperal septic diseases.		Accidents of childbirth.	
Merioneth	3·9	Denbigh	4·6
Cardigan	3·7	Merioneth	4·2
Denbigh	3·1	Cardigan	4·1
Glamorgan	3·1	Radnor	4·0
Carnarvon	3·0	Carnarvon	3·8
Carmarthen	3·0	Brecknock	3·8
Brecknock	2·7	Montgomery	3·5
Flint	2·6	Pembroke	3·4
Montgomery	2·5	Glamorgan	3·2
Anglesea	2·4	Carmarthen	3·1
Radnor	2·3	Flint	2·9
Pembroke	2·0	Anglesea	2·4
Mean for Wales	2·8	Mean for Wales	3·5
Mean for England and Wales	2·1	Mean for England and Wales	2·4

Flintshire, Montgomeryshire, and Anglesea follow and these may be described as mostly agricultural and flat counties. The death-rate is lowest in Radnorshire and Pembrokeshire, two typical agricultural and somewhat flat counties. The rate for all except Pembrokeshire is above the average for England and Wales. The death-rate from accidents of childbirth is highest in Denbighshire, Merionethshire, Cardiganshire, and Radnorshire; then come Carnarvonshire, Brecknockshire, and Montgomeryshire; followed by Pembrokeshire, Glamorgan, Carmarthenshire, Flintshire, and Anglesea. The rate is above that for England and Wales in all the counties except Anglesea, the rate for which county coincides with the general rate.

In the following table the Welsh counties are arranged according to density of population:—

TABLE XII.—*Welsh Counties in order of Density of Population and Death-rates.*

—	Density of population. (Acres to a person.)	Comparative increase or decrease per cent.
Glamorganshire	0·6	+25·1
Flintshire	2·0	+ 5·7
Carnarvonshire	2·9	+ 7·3
Denbighshire	3·4	+10·2
Anglesea	3·4	+ 0·9
Carmarthenshire	4·4	+ 3·6
Pembrokeshire	4·4	− 0·4
Cardiganshire	7·1	− 3·9
Merionethshire	8·7	− 0·1
Montgomeryshire	9·0	− 5·3
Brecknockshire	8·1	+ 5·0
Radnorshire	13·3	+ 6·7
England and Wales	1·2	+12·1

It follows, therefore, that the death-rate from puerperal septic diseases is above the mean (2·1 per 1000) for England and Wales in all the Welsh counties except Pembrokeshire. With respect to accidents of childbirth the death-rate is above the mean except in Anglesea. Glamorgan is the only county that may be termed "densely populated"—i.e., with less than one acre to a person—while the remainder may be termed "sparsely populated."

From a consideration of the above figures it does not seem that the density of population is a factor of much importance in determining puerperal mortality; on the contrary, the mortality from puerperal fever and from accidents of childbirth show a marked tendency to prevail in those counties where the only features in common between them are that they are mountainous, hilly, and sparsely populated, and that consequently locomotion is tedious and medical assistance is difficult to obtain in time. On the other hand, the mortality seems to be generally lowest in the flatter counties.

I now give the figures for the counties of Monmouth, Salop, and Hereford.

TABLE XIII.—*Showing the Annual Death-rate per 1000 from Puerperal Septic Diseases and Accidents of Childbirth in the Counties of Monmouth, Salop, and Hereford during the Period 1881–1900 (20 years).*

Year.	Monmouthshire.		Salop.		Herefordshire.

1900	4·1	4·5	1·6	1·6	1·9	1·9
Mean for 20 years	2·8	3·0	2·3	2·7	2·4	2·7
Mean for England and Wales	2·1	2·4	2·1	2·4	2·1	2·4
Glamorganshire ...	3·1	3·2	3·1	3·2	3·1	3·2

A. = Puerperal septic disease. B. = Accidents of childbirth.

The above figures are what was expected. Those for Monmouthshire as nearly as possible correspond with those for Glamorgan and the physical and industrial conditions of the two counties are almost identical. Again, the figures for Salop and Herefordshire are practically the same and practically also the same as those for the flat and agricultural counties of Wales such as Anglesea, Flintshire, and others. These figures tend to bear out the truth of my former remarks.

THE REGISTRATION COUNTY OF GLAMORGAN.

This registration county had according to the census enumeration of 1901 a population of 866.250, considerably over one half of the population of Wales. It covers 576 537 statute acres. The increase in its population has been phenomenal, as the following figures will show:—

Year.	Population.
1801	70,879
1811	85,069
1821	120,073
1831	126,612
1841	171,188
1851	231,849
1861	317,752
1871	397,157
1881	511,433
1891	687,218
1901	866,250

The county is divided by nature into a northern hilly country, "the Hills," cold, wet, and sterile; and a southern low-lying country, "the Vale of Glamorgan," or the "Garden of Wales," milder in climate and more fertile. The former is severed from the latter by steep slopes where the coal measures crop out in the south of the mineral basin. The hills are mining districts, while the lower grounds, or the Vale of Glamorgan and Gower, are purely agricultural and sparsely populated. The surface of the coalfields may be looked upon as a great plateau with an elevation of from 600 to 1200 or more feet above the sea level and intersected by a series of more or less parallel valleys excavated to a depth of from 500 to 800 feet below its general level and at the bottom of which run rapid streams. The valleys in the eastern region—the Rhymney, the Taff, and their tributaries the Rhonddas and the Cynon—trend, as a general rule, towards the south-east; those of the middle—the Ely, the Ogmore, the Garw, and the Llynvi—to the south; while those of the western region—the Avon, the Neath, the Tawe, and the Loughor—trend towards the south-west. They are generally narrow and deep, opening upon the "Vale" or the Bristol Channel, and they offer great facilities for mining and the carrying away of minerals along the railroads and canals which are constructed along most of them. All the coal-miners are in the hills and their valleys where I shall show that puerperal mortality is exceptionally high.

On analysis Table XIV. shows that the mortality rate from puerperal fever for 1881–1900 exceeds the average for England and Wales very considerably except in the registration districts of Pontardawe, Cardiff, and Gower. (Fig. 3.) The mortality rate from accidents of childbirth exceeds that for England and Wales in all the registration districts and very considerably so in five of these eight districts. (Fig. 4.) The highest death-rate from puerperal septic diseases occurred in the Pontypridd and Merthyr district and the highest death-rate from accidents of childbirth in Pontardawe and Pontypridd. The figures also for the various years show considerable variations and it is noteworthy that no deaths from puerperal septic diseases occurred in Pontardawe, during 1884, 1887, 1889, 1895, and 1896, or in Gower during 1881 and ten consecutive years from 1890. There were no deaths from accidents of childbirth in Pontardawe in 1882 and in Gower during 1883, 1888, 1889, 1890, 1893, 1895, and 1900. Although some 140,000 of the population live in what are termed rural districts it is not more than from 20,000 to

A. = puerperal septic diseases. B. = accidents of childbirth.

30,000 that live under true rural circumstances and these are the people of Gower, Vale of Glamorgan, and of the Neath and Pontardawe districts partly. I have no separate figures for the Vale of Glamorgan, which includes portions of several sanitary districts, mixed industrial and agricultural.

The Cardiff registration district has an acreage of 77,655 (0·3 acre to a person) and includes the county borough of Cardiff (estimated population 176,313), Penarth (14,228), and Barry (27,030) urban districts, together with the very extensive rural district of Llandaff and Dinas Powis, which is a scattered industrial and agricultural district with a population of 20,047. Its sanitary condition may be described as satisfactory and confinements are attended generally by medical men and midwives. Trained midwives can be had when required and there is no difficulty whatever, in securing medical assistance if and when required except in the more rural portions of it. It has been estimated that over half the confinements of Cardiff have been attended by midwives but no reliable figures can be given, whereas in residential towns within the area, such as Llandaff, Penarth, and Llanishen, nearly all confinements are attended by medical men and trained midwives. In Cardiff there are about 60 or more women who hold themselves out as midwives and practise for gain and the number of midwives for the whole registration district—viz., Cardiff, 60; Barry, 22; Penarth, 6; and Llandaff and Dinas Powis, 9—making a total of about 97. It may be further stated that the district is flat but somewhat undulating and that locomotion is easy. Here the mortality from puerperal septic diseases coincides with that for England and Wales, whilst that from "accidents of childbirth" is somewhat higher.

The Pontypridd registration district has an acreage of 50,457 (0·3 acre to a person) and includes the important urban districts of Pontypridd (population 32,319), Rhondda (122,310), and the rural district of Llantrisant and Llantwit Vardre (11,844). The first and second districts are situated on both sides of the River Taff in its long, narrow, deep, and tortuous valley, bounded on either side by high mountainous ridges. The river now contains but little sewage but a considerable amount of coal-dust, giving it an inky appearance. The water-supply, which is surface-collected and brought from a distance, is satisfactory although occasionally in dry seasons it is short. In both districts there are a few congested localities and in the latter some cellar dwellings. In both cases there is a considerable amount of overcrowding of persons in houses resulting from the habit of taking in lodgers. By far the most insanitary conditions in these districts which have been allowed to remain are the presence along the banks of the river near public roads and dwellings of enormous deposits of decomposing house refuse, and although the authorities concerned have been for many years discussing the advisability of erecting various refuse destructors and other remedies still these exist and continue to emit malodorous and unquestionably dangerous gases. I cannot prove definitely that typhoid or puerperal fever cases can be traced directly to these but I strongly suspect that they act as foci of infectious disease and that those who have the misfortune of living in their vicinity are rendered more susceptible to these diseases. These two districts may be described as essentially mining districts. There is yet another district making up this registration district—viz., Llantrisant and Llantwit Vardre. This contains a few and very old dilapidated villages and a few typical mining localities. Indeed, it may be described as a scattered mining and agricultural area. The water-supplies are satisfactory, the roads are good, and the means of locomotion are sufficient and available. There is no difficulty in obtaining medical aid in a short time. Throughout the registration district by far the majority of confinements are attended by untrained and ignorant midwives and comparatively few are attended by the medical men who are in charge of the various colliery practices. On referring to Table XIV. it will be seen that the average death-rate from puerperal fever and accidents of childbirth are exceedingly high.

The Merthyr Tydfil registration district has an acreage of 65,805 (0·4 acre to a person) and includes the urban districts of Merthyr Tydfil (population 69,228), Aberdare (43,357), Mountain Ash (31,093), and the so-called rural district of Gelligaer and Rhigos (18,169). The district comprises portions of three important mining valleys—viz., the Rhymney, the Taff, and the Cynon, and along each of them runs a river bearing the same name and containing but very little sewage matter. The district of Merthyr Tydfil may be described as containing a large number of congested areas and many very dilapidated back-to-back, back-to-earth, and cellar dwellings, without through ventilation and overcrowded. The outlying localities are in a more satisfactory sanitary condition. The water-supply, which is surface-collected from the Old Red Sandstone, is both good and plentiful. Most of the houses are drained and connected with the public sewer constructed over 30 years ago. Aberdare is in a fairly good sanitary condition, but here again there are a few congested areas along the river banks and here and there throughout the district will be found some back-to-earth and cellar dwellings without through ventilation. The water-supply is good and plentiful, being surface-collected and obtained from the Old Red Sandstone. Mountain Ash is a typical mining district situated in the same valley as Aberdare. The majority of the houses are of recent construction but there are several insanitary spots where the drains and sewers are defective and neglected. The water-supply, which is surface-collected, is good and plentiful.

Gelligaer and Rhigos district is situated in the Rhymney Valley on one side of the river and contains several typical mining villages, some of which are old. All the centres are sewered or being sewered. The water-supply is short during dry weather. Throughout the whole of this registration district there is no difficulty whatever in summoning medical aid. By far the majority of confinements are attended by unskilled and untrained midwives. On referring to Table XIV. it will be seen that the death-rates from puerperal fever and the accidents of childbirth are excessively high.

The Bridgend registration district has an acreage of 110,571 (1·6 acres to each person) and is situated partly in the Vale of Glamorgan and partly in mining valleys of Mid-Glamorgan. It includes the old market town of Bridgend (population 6063), Cowbridge (1202), a small seaside resort called Porthcawl (1872), an extensive agricultural area, together with the mining districts of Maesteg (15,012) and Ogmore and Garw (19,907). These mining centres are situated in narrow valleys, especially the Garw, where some few years ago puerperal fever was epidemic. In these valleys there occurred an epidemic of this malady in 1892–93. To this I shall refer presently. Bridgend and the valleys above it are now being sewered but the river up to the present has been the sewer of the locality and its condition in all probability was associated with the perennial prevalence of typhoid fever at Bridgend. The water-supply for all these places is fairly satisfactory. The majority of confinements are attended by untrained and unskilled midwives and few only, except in the older towns, by medical men. There is but little difficulty in obtaining skilled medical assistance at short notice. On reference to Table XIV. it will be seen that the mortality from "puerperal septic diseases" is excessively high, while that from "accidents of childbirth" is above the average.

The Neath registration district has an acreage of 87,811 (1·2 acres to a person) and includes the old towns of Neath (population 13,732), Briton Ferry (6961), Aberavon (7553), Margam (9014), Glyncorwg (6450), and Neath rural district (27,343), the last named being mostly rural in character but also containing several mining villages of recent growth. The sanitary condition of Aberavon, Briton Ferry, and Neath is unsatisfactory and there are a large number of courts, alleys, and areas in the two latter which are liable to become flooded and where the houses are overcrowded upon area and with persons. The water-supply is inadequate. The majority of confinements here are attended by unskilled and untrained midwives and there is no difficulty except in the outlying farmhouses in procuring skilled medical assistance at short notice.

Pontardawe registration district has an acreage of 34,000 (1·6 acres per person) and is conterminous with the Pontardawe rural district. It is much smaller in extent and population than the other registration districts, consequently the figures given, although extending over 20 years, are not quite so reliable. It includes several important industrial and mining centres and there are practically in it no congested areas. The water-supply is good and abundant and in nearly all instances the sewage is not stored in cesspools but taken away on land or disposed of otherwise. The death-rate from puerperal fever is below the mean for England and Wales, but that from accidents of childbirth is by far the highest in the county. Indeed, for one year, 1893, it amounted to 12 2 per 1000, in 1900 to 8 5, and in 1898 to 9·4, figures which almost approach those recorded in lying-in hospitals about 100 years ago. I have no explanation to offer for this, for there is no difficulty in procuring skilled medical assistance at short notice. I may mention, however, that many young women are employed at the tinplate works.

The Swansea registration district has an acreage of 36,056 (0 2 acre per person) and comprises the county borough of Swansea (population 95,133) and the scattered mining and agricultural district of Llangyfelach (29,989). The sanitary condition of the rural portion is far from being satisfactory and none of the populous mining centres are sewered. The water-supply is inadequate and unsatisfactory. There are no congested centres and but little overcrowding of persons. The majority of confinements are attended by unskilled and untrained midwives. The death-rates from puerperal fever and accidents of childbirth are considerably above the average.

The Gower registration district has an acreage of 41,110 (3·6 acres to a person) and includes the purely agricultural area of Gower (population 7266) and the small seaside resort of Oystermouth. There are no congested areas and the whole peninsula is a flat but undulating country. There is no difficulty in getting skilled medical assistance at short notice. Midwives attend the majority of confinements.

Below are given similar figures for the county boroughs of Cardiff and Swansea and the urban districts of Merthyr Tydfil and Rhondda, all situated in Glamorganshire in four different registration districts. The figures given extend over ten years.

TABLE XV.—*Showing the Annual Death-rate per 1000 from Puerperal Septic Diseases and Accidents of Childbirth for the County Boroughs of Cardiff and Swansea and the Urban Districts of Rhondda and Merthyr Tydfil during the period 1891–1900 (ten years).*

A. = puerperal septic diseases. B. = accidents of childbirth.

(*To be continued.*)

THE LYMPHATICS OF THE LARYNX AND THEIR RELATION TO MALIGNANT DISEASE OF THAT ORGAN.

BY PHILIP R. W. DE SANTI, F.R.C.S. ENG.,
SURGEON TO THE THROAT, NOSE, AND EAR DEPARTMENTS, WESTMINSTER HOSPITAL.

Anatomy of the laryngeal lymphatics.—In nearly all textbooks on laryngology but scant and imperfect notice is taken of the lymphatics of the larynx and of the subject of their involvement in malignant disease of that organ, yet the matter is one of considerable importance, not only from a pathological point of view but clinically with regard to prognosis, especially prognosis depending on operative treatment. A considerable amount of work has, however, of late been accomplished by anatomists in this field and it is the object of this paper to give an account of the most recent work on the lymphatics of the larynx and to discuss the anatomical facts in their relation to the spread of malignant disease of the larynx to the lymphatic glands. Apparently the first really accurate description of the laryngeal lymphatics was given by Teichmann who particularly drew attention to the distribution of the terminal vessels in the mucous membrane of the larynx. Sappey's (1874) well-known researches on the lymphatics completed the description of these vessels and described the general arrangement of the laryngeal lymphatic radicles, their continuation in the lymphatic channels, and final distribution to the glands. In 1887 Poirier[1] investigated the distribution of these lymphatics and pointed out that whilst most anatomists were agreed as to the presence of two regions in the larynx essentially different as regards the number and importance of the lymphatic vessels, the one supraglottic in the mucous membrane of which there is a rich network of lymphatics, and the other subglottic in which the lymphatics are particularly small and the meshes few, this condition becoming more accentuated as one follows them down towards the trachea, yet the intervening region, that practically of the true vocal cords, had not been adequately investigated.

The results of Poirier's injections of the lymphatics of the larynx may be summed up as follows. 1. As the lymphatic network in a subglottic injection is traced upwards it appears to end abruptly about one millimetre from the free border of the inferior or true vocal cords. 2. In a supraglottic injection the lymphatic system as it invades the superior vocal cords is found also to become altered; though lymphatic radicles traverse the superior cords, still they are found to become more and more attenuated as they reach their free border. 3. The lymphatics of the true vocal cords, although difficult to inject, are found to be present but only in small numbers and of small size. Poirier also found injections of the subglottic region difficult and increasingly difficult the greater the age of the patient. Most of his successful injections were made in larynges taken from children from one to seven years of age. On the rare occasions in which he was able to inject the lymphatics in old people he found the mucous membrane of the larynx much less thick than in children and adults and he concluded that there was a progressive atrophy normally of the lymphatic system in the larynges of old people and that this attenuation and atrophy not only applied to the laryngeal mucous membrane but also to the lymphatic ducts that go to the neighbouring glands. Most (1899) applied in the study of the laryngeal lymphatics the method of Gerota and recently Cunéo[2] has published an article giving his results, his conclusions being based on the results he obtained by injecting several larynges in the same manner as Most and confirming Most's results. I have personally also made some injections of the laryngeal lymphatics by Gerota's method and find that the results substantially agree with those of Poirier, Most, and Cunéo. Gerota's method of injection is as follows. Two grammes of Prussian blue to which three grammes of pure spirit of turpentine have been added are rubbed down in a mortar; 15 grammes of sulphuric ether are added and the whole filtered through a double layer of linen. The solution must be used at once for injection. The injection should be made with a syringe holding from 10 to 20 cubic centimetres. To the end of the syringe is fixed a small adjustment which receives the glass needle for puncturing the tissues. The larger end of the glass needle is wrapped round with a waxed thread to prevent leakage. The point is drawn out in the flame; it must not be too fine or yet too thick. The mixture is injected into the tissues under low pressure only. By this method a much better knowledge of the lymphatics of certain parts of the body unsuitable for injection by mercury has been obtained.

Cunéo's account of the lymphatics of the larynx; the lymphatic radicles.—The lymphatics of the larynx originate in a network that covers the whole of the internal surface of the larynx and is densest where the mucous membrane is thickest. It is divisible into two areas, a superior and inferior. The superior area in which the terminal meshwork is very dense and easy to inject includes all the portion of the laryngeal mucous membrane above the glottis, epiglottis, aryteno-epiglottidean folds, inter-arytenoid region, and superior vocal cords. (In my injections I found an alteration in the number and size of the lymphatic radicles in the superior vocal cords—they became less in number and smaller in size as they approached the free border of the superior cords; these results agree with those of Poirier.) The inferior area includes the mucous membrane of the larynx below the glottis. At this level the network is less dense and in all cases more difficult to inject than that of the superior area. These two areas are relatively independent of one another. They are, as a matter of fact, separated by an intermediary zone formed by the inferior true vocal cords, at which level the lymphatic radicles are even more rare and attenuated, although not entirely absent. At the level of the posterior wall of the larynx the two areas extend without any very clear line of demarcation. If an injection at the level of the inferior true vocal cord be pushed the material injected enters the vessels of the superior network. The lymphatics of one-half of the larynx do not communicate with those of the opposite side along the anterior median line but along the posterior median line the intercommunications are very numerous. The infraglottic meshwork is directly continuous with the tracheal network; there is no line of demarcation at all. Similarly the supraglottic meshwork is directly continuous with the network covering the mucous membrane of the pharynx and base of the tongue. The middle group of post lingual vessels receive vessels that come from the anterior surface of the epiglottis itself. All these facts are of importance from the point of view of the local spread of laryngeal carcinoma.

Distribution of the lymphatic channels arising from the lymphatic meshwork.—Each of the two areas has a distinct set of efferent vessels. The trunks arising from the supraglottic network run towards the lateral parts of the epiglottis and ary-epiglottic folds and then pierce the thyro-hyoid membrane at the point of entry of the superior laryngeal artery. After piercing the thyro-hyoid membrane these collecting trunks divide into three sets: an ascending group of one or two in number which cross the hypoglossal nerve and end in a gland situated just below the posterior belly of the digastric muscle; a horizontal group which empties into the glands placed on the internal jugular vein at the level of the bifurcation of the common carotid; and a descending group ending in glands of the same chain at a lower level—namely, the middle part of the lateral lobes of the thyroid gland. Sometimes one or two small glands are found on the thyro-hyoid membrane itself, but they do not apparently receive lymphatics from the larynx itself—their afferent vessels come from the lateral aspects of the pharyngo-larynx.

The efferent vessels of the infraglottic region are divisible into two groups—one anterior, the other posterior. The anterior group (supracricoid) consists of from three to four trunks which pierce the crico-thyroid membrane near the mid-line. Some of these trunks end, according to Poirier, in the prelaryngeal glands, others in a pretracheal gland, and still others in one of the glands of the middle or inferior sterno-mastoid chain (Most). The prelaryngeal and pretracheal glands form part of a chain described as the deep anterior cervical chain (Poirier). This chain consists of three distinct groups or masses of glands. 1. A prelaryngeal lot first noticed by Engel the existence of which has been confirmed by the work of Poirier who found the group present 49 times out of 100. Usually only one gland is present, which in the adult is of about the size of a pea and tends to atrophy in old age. It is found generally in the middle of the V-shaped space formed by the two crico-thyroid muscles, though occasionally it is overlapped by the inner border of one of these muscles. In one out of six cases a second gland of about the size of a pin's head has been found at the level of the top of the V-shaped space. Occasionally a gland is found on the upper edge of the isthmus of the thyroid gland (Mascagni, Most, Roubaud), and rarely a gland in front of the thyroid cartilage close to its anterior border. 2. A prethyroidean mass situated in front of the isthmus of the thyroid; this group is but rarely present. 3 A pretracheal mass usually consisting of one gland of the size of a small pea and situated about one and a quarter centimetres above the sternal notch. There may, however, be more than one pretracheal gland.

The afferent vessels of the prelaryngeal glands are some of the lymphatics of the middle lymphatic pedicle of the larynx and those of the pretracheal come partly from the thyroid body and partly from the prelaryngeal glands. The efferent vessels from the prelaryngeal, prethyroidean, and pretracheal glands empty themselves into the lowermost glands of the sterno-mastoid chain.

The posterior or infracricoid group consists of from three to five trunks which pass over the crico-tracheal fascia at the junction of the lateral and posterior aspects of the trachea. These trunks end in from two to five glands running parallel with the recurrent laryngeal nerve. These glands collect vessels from the thyroid body, the lymphatics of the inferior pedicle of the larynx, and the vessels from the cervical portion of the trachea and œsophagus. Their efferent vessels end in the lowermost glands of the sterno-mastoid chain and supraclavicular glands and not in the mediastinal glands.

---

[1] Bulletins de la Société Anatomique, 1887, 15e serie.

[2] Gazette des Hôpitaux, No. 141, 1902.

To sum up, the lymphatic channels emanating from the larynx empty themselves into the glands placed under the sterno-mastoid muscles, into the prelaryngeal glands, into the glands accompanying the recurrent laryngeal nerves, and additionally into the supraclavicular glands. The sub-sterno-mastoid group of glands must be considered as the chief set of glands to receive finally the lymphatics of the larynx; the prelaryngeal, pretracheal, and recurrent groups are, as Cunéo remarks, simple glandular points placed as interruptors on the line of the lymph vessels going from the infraglottic area to the deeper group of sterno-mastoid glands.

Application of these anatomical facts to the extension of malignant disease of the larynx by the lymphatics.—In the year 1850 Krishaber divided cases of malignant disease of the larynx into two classes, those of intrinsic and those of extrinsic origin. He applied the term intrinsic to those cases in which the primary site of origin was the true or false vocal cords, the ventricles, or the parts immediately below the true vocal cords (subglottic), and the term extrinsic to tumours arising in connexion with the epiglottis, ary-epiglottic folds, inter-arytenoid space, &c. The reason of this division was a two-fold one—pathological and clinical. He laid down the dictum that "as long as the cancer remains intrinsic there is no glandular enlargement; when it is extrinsic the glands are infected." Schwartz uses practically the same terms—namely, "caviteires et marginaux." Cunéo, however, has quite recently suggested that Krishaber's statement is incorrect and classifies malignant disease of the larynx as supraglottic, infraglottic, and glottic in origin. He believes this division to be scientifically correct and based not only on the arrangement of the laryngeal lymphatics, as already described, but on ascertained clinical facts as regards the tendency to lymphatic involvement. Cunéo considers Krishaber's classification and formula inconvenient "in that it includes under the same heading varieties behaving as regards glandular infection in very different ways. One would have to admit that epitheliomas attacking the superior vocal cords, which are very rich in lymphatics, involve the glands equally late as in epitheliomas attacking the inferior vocal cords, the lymphatics of which are extremely few and ill-developed." He goes on to state that he has seen and collected cases showing that glandular infection occurs early when the superior vocal cords are the site of origin of laryngeal cancer. Accordingly, he suggests the following modification: "Glandular infection is more certain and more extensive in supraglottic cancer than in glottic or subglottic cancers." To my mind Cunéo fails to make out a sufficiently clear case for the abandonment of Krishaber's well-known classification and formula.

Although admitting the anatomical fact that injection of the laryngeal lymphatics shows that the lymphatic network is better marked in the area of the superior vocal cords than in the subglottic and glottic regions of the larynx, yet his statement that clinically there is a tendency to early implication of the glands in cases of carcinoma originating in the superior vocal cords is open to question and is most decidedly not borne out by the experience of most English laryngologists. On the contrary, those who have had most experience of malignant disease of the larynx in this country, such as Semon, Butlin, and others (and these two have had an experience second to none), have found that there is no more tendency to early infection of the glands when the disease originates in the false vocal cords than when attacking the true vocal cords or subglottic space. Is it not possible that Cunéo may be mistaken on this point on account of the undoubted fact that cases of malignant disease originating in the superior vocal cords may not for some length of time give rise to any obvious symptoms and therefore are not apt to come under notice until the disease is much advanced, whereas in malignant disease of the true vocal cords symptoms, especially hoarseness, are apt to be present in the earliest stage? This might easily account for Cunéo's conclusion as to early infection of the glands, for if two cases, one of cancer of the false vocal cords and one of the true vocal cords, were to be seen and diagnosed at the same stage, and that an early one, it would be found that in neither case were the lymphatic glands implicated. No; many years have now elapsed since Krishaber's classification and formula were adopted and clinical experience has only tended to prove that his classification is a correct one and that so long as malignant disease is limited to the interior of the larynx (intrinsic) glandular infection is rare, but that if the external parts of the larynx (extrinsic) be affected early glandular infection is the rule. There seem, therefore, no sufficient grounds at present to abandon Krishaber's division; no useful purpose would be served thereby and only confusion that already exists in abundance rendered worse confusion.

Extrinsic carcinomata all present certain characteristics tending to spread towards the upper opening of the larynx and the lateral parts of the pharyngo-laryngeal region. This progress is rapid and sure when the epiglottis or ary-epiglottic folds are primarily attacked, less so when the arytenoid region is attacked. Although extrinsic carcinoma reaches the final stage of its evolution by invading the extra-laryngeal parts it is particularly at the level of the posterior aspect of the thyro-hyoid membrane that it is liable to show itself externally—i.e., to ulcerate through. Extrinsic carcinoma tends to become arrested, at any rate for some time, in its growth downwards by the true vocal cords. Intrinsic carcinoma attacks most frequently the true vocal cords (29 out of 117 cases—Baratoux; 15 out of 55—B. Fraenkel, Semon), next in frequency the superior or false vocal cords, and lastly the subglottic region. Carcinoma of the true vocal cords is conspicuous by virtue of the slowness of its evolution. It tends to spread at first towards the opposite vocal cord and later to the supraglottic region. Similarly when the superior vocal cords are attacked extension is towards the supraglottic region.

Subglottic carcinomata are rare; out of 486 cases Sendziak only collected five. They tend to spread downwards and invade the trachea. Their growth upwards is usually checked by the true vocal cords, although in a case observed by Cunéo the true vocal cords were invaded, the parts above, however, being quite free. With the exception of malignant disease originating in the epiglottis or arytenoid region the disease tends to remain limited at its commencement to one-half of the larynx. Sooner or later, however, the neoplasm tends to attack the opposite side. A few cases have been reported in which the opposite side has become affected by contact, but usually it is by direct continuous invasion. This most often occurs at the level of the posterior aspect of the larynx, although it has been observed to invade the opposite cord through the anterior commissure (Semon). The distribution of the lymphatics can to a great extent explain these different particulars in the local extension of cancer of the larynx.

The arrest for a long time of growths reaching to the inferior true vocal cords is the result of the attenuation of, and diminution in the number of, the lymphatics at this point. In extending towards the superior laryngeal orifice and lateral aspects of the larynx extrinsic carcinoma only obeys the general law observable in the extension of all epitheliomas—namely, a preference to follow the course of the lymphatic stream. The connexion of the lingual lymphatics with those originating on the anterior aspect of the epiglottis explains the tendency to extension of malignant disease of the epiglottis to the base of the tongue. The continuity of the subglottic meshwork with that of the trachea equally accounts for the extension of subglottic cancer towards the trachea. The small number and ill-developed condition of the lymphatics of the inferior vocal cords account mainly for the slow evolution of epithelioma attacking that region. Finally, the relative independence of the lymphatics of each half of the larynx accounts for the non-involvement of the opposite side of that organ for a period at all events more or less lengthy.

Like all epitheliomata cancer of the larynx tends eventually to invade the lymphatic glands; in fact, it is the rule in late cases. Schleier has noticed it 20 times out of 125 cases and Sendziak notes 54 cases out of 486. It is only fair, however, to say that other observers give a much higher percentage—Juraz nine out of 21 and Schwartz 13 out of 28 cases. At the same time lymphatic infection is fairly rare if the growth be limited to the true or false vocal cords, particularly to the anterior two-thirds of the true cords. It is also uncommon in cases of subglottic origin. It is well to remember, as pointed out by Cunéo, that enlargement of the glands in a case of epithelioma of the larynx does not necessarily mean malignant infection. The enlargement may be due to septic infection from a septic malignant-ulcer or to some septic lesion of the pharynx. Much more attention should be given in all cases of post-mortem examinations performed on patients dying from malignant disease of the larynx to the microscopic examination of the neighbouring lymphatic glands; in two cases lately under my care, both advanced cases of intrinsic carcinoma and in which ante mortem no infection of the glands could be made out, post-mortem examination microscopically of the cervical glands gave no evidence of secondary infection.

In cases of epithelioma of the epiglottis and ary-epiglottic folds very early glandular infection is the rule. I have seen most extensive masses of fixed hard glands in such cases. The fact, nevertheless, remains that in many cases (intrinsic) glandular involvement occurs relatively late. Cunéo mentions several causes to explain this early immunity of the glands. First of all he points out that the major number of laryngeal carcinomata are squamous epithelioma (248 cases out of 486—Sendziak) and he goes on to state that it is well known that this variety of growth generally attacks the glands somewhat late. This, however, is certainly incorrect; for instance, in epithelioma attacking the tongue or tonsil very early and extensive implication of the glands is the rule. Again, he thinks cancer of the larynx tends frequently to become pedunculated and to grow into the cavity of the larynx without extending much beyond the border of its base of origin and points out that pedunculated cancers growing into a cavity do not as a rule invade the glands until a very late stage, a good example being papillary carcinoma of the bladder.

Whilst admitting that occasionally laryngeal epithelioma is pedunculated and may possibly for this reason not invade the glands until a late stage, yet in my experience it is exceptional to come across a case of laryngeal epithelioma that is pedunculated. Usually the neoplasm is sessile with a broad base of origin and much infiltration. The only rational explanation seems to me to lie in the distribution of the lymphatic meshwork of the larynx; if certain parts, such as the epiglottis and ary-epiglottic folds, are very rich in lymphatics and consequent glandular infection is both certain and early in appearing, it is seen that in other parts, such as the subglottic and less so the false vocal cords, the lymphatic meshwork is much less developed and that on the true vocal cords, one of the sites of election for epithelioma, the lymphatics are so few in number that their injection is a matter of considerable difficulty. In epithelioma attacking these parts glandular infection is as late in appearing as it is early when attacking the epiglottis or ary-epiglottic folds.

Distribution of glandular infection.—Bearing in mind the anatomical description of the glands already given one would expect infection to show itself in three groups of glands—the substerno-mastoid, the prelaryngo-tracheal, and the recurrent laryngeal. As a matter of fact all the glands included between the posterior belly of the digastric and the clavicle may become infected in cases of laryngeal cancer. There is nothing especially characteristic in their mode of invasion. Infection of the prelaryngo tracheal glands is decidedly rare although Most has collected a few cases. Similarly only a few cases are on record of infection of the recurrent group (Juraz, Fraenkel, Bergeat, Manver, and Most). In all the verification has been post mortem, as malignant disease of these glands owing to their small size and depth cannot be recognised clinically. The order in which the glands become infected varies according to the site of origin of the growth. If of extrinsic origin it is particularly likely to occur in the upper group of glands of the sterno-mastoid chain, and if subglottic in the lower group. As a rule the gland which is first found to be enlarged and that is most often met with in intrinsic carcinoma is placed at the level of the anterior border of the sterno-mastoid muscle about the height of the space which separates the hyoid bone from the thyroid cartilage (Schwartz) So long as the disease remains limited to one-half of the larynx glandular infection occurs only on the affected side. Most and Roubaud were unable to find a single case in which a unilateral laryngeal cancer had caused involvement of the glands on both sides. This is in strict accordance with the

cricoid plate glandular infection on both sides of the neck may occur.

These particular points in the pathological anatomy of cancer of the larynx carry certain practical deductions. Firstly, in early intrinsic carcinoma of the larynx of limited extent the disease can most thoroughly be dealt with by the operation of thyrotomy (or laryngo-fissure). It is very necessary, however, to bear in mind two important points with regard to this operation: (1) that the disease is frequently more extensive than the laryngeal picture has shown it to be and therefore the consent of the patient must be obtained to go further if at the time of the operation it is deemed necessary and to perform unilateral laryngectomy; and (2) that the fact of having to remove small portions of the cartilages of the interior of the larynx as well as the affected soft parts does not justify the operation being called a "partial extirpation of the larynx" in contradistinction to the term thyrotomy. As Semon has pointed out, the difference between a real partial—that is to say, a complete or nearly complete—removal of one-half of the larynx and a thyrotomy with extraction of a small piece of the cartilaginous framework is so great, owing not only to the much more extensive nature of the operation for partial laryngectomy but also to the nature and technique of the after treatment and dangers of complication, that the imaginary difference between a thyrotomy with simple extraction of the soft parts and a thyrotomy in which in addition to the extraction of the soft parts an insignificant piece of cartilage has also to be removed is ridiculous. Such cases must be reckoned in the category of simple thyrotomies. Secondly, in cases of extrinsic carcinoma or of intrinsic too extensive to be dealt with by thyrotomy the tendency of the disease to remain limited for a certain length of time to one half of the larynx justifies the performance of unilateral laryngectomy. The question as to the advisability of excising the neighbouring glands is one of great importance and unfortunately there is a considerable divergence of opinion on the matter. Out of notes of 298 partial or complete laryngectomies collected by Sendziak extirpation of the glands is only mentioned 25 times, a percentage of 8. Cunéo whilst admitting the tendency to comparatively late invasion of the glands and the rarity of recurrence in the glands (five cases out of 110 partial and seven out of 188 total laryngectomies) considers this proportion—i.e., 4·5 per cent. in the former and 3·9 per cent. in the latter—sufficient to justify the systematic extirpation of the set of glands liable to infection in all cases of laryngeal cancer, whether enlarged or not. The operative results of English laryngologists do not warrant the recommendation to extirpate in all and every case of malignant disease the set of glands liable to infection.

The whole question seems to me to turn on two main points: (1) the site of origin of the disease; and (2) the stage in which the disease is diagnosed. If an epithelioma of the larynx of strictly intrinsic origin is seen and diagnosed in an early stage and whilst therefore it is of limited origin the operation of thyrotomy as carried out in this country by Butlin, Semon, and others is amply sufficient to eradicate the disease. In the absence of obvious glandular involvement experience has shown that there is no need to perform a set operation to remove the group of glands liable to infection. Both Butlin and Semon, who are warm advocates of the operation of thyrotomy for early intrinsic carcinoma of the larynx, have had most brilliant results—results unequalled in the surgery of cancer in other parts of the body For instance, if one takes Semon's cases operated on by him between June, 1891, and July, 1898 we find he performed thyrotomy on 12 patients. Ten of these 12 patients have been completely and lastingly cured—a percentage amounting to 83 3. In none of these cases was it deemed necessary to extirpate any glands. On the other hand, in much advanced cases of intrinsic cancer of the larynx which necessitate removal of one-half of the larynx the corresponding glands should be removed whether they are felt to be enlarged or not. Also, in any given case of extrinsic origin, bearing in mind the certainty of early involvement of the glands, a set operation for their removal, whether enlarged or not, should always be the routine practice.

To sum up briefly this question one would agree with Cunéo that extirpation of the group of glands liable to infection should be systematically carried out in all cases of malignant disease of the larynx with the exception of those cases of intrinsic origin which are seen early, are of limited extent, and in which there is no clinical evidence of glandular infiltration.

Stratford place, W.

ON THE ETIOLOGY OF SCURVY.[1]

BY MYER COPLANS, M.B. LOND., D.P.H. CAMB.,
LATE CIVIL SURGEON ATTACHED TO THE ROYAL ARMY MEDICAL CORPS, SOUTH AFRICA.

As I have not dealt at all fully with the clinical aspect of the cases referred to in this paper I may perhaps state here that they conformed in every particular to what, I take it, would be regarded as typical scurvy. As to this no question has been raised, but I make the statement with the view of clearing up any doubts which may arise on this point. Briefly the subjects of these cases presented during life spongy bleeding gums, lassitude, anæmia, and breathlessness on exertion, followed later by lameness associated with synovitis in the joints, and hæmorrhages with brawny indurated swellings in one or both of the lower limbs. The urine was slightly acid. The blood showed marked poikilocytosis in the red discs. There were no nervous lesions. Death took place from cardiac failure usually and post mortem the blood was fluid; there were subserous, submucous, subpleural petechiæ. The heart was thin and pale, the right side being dilated, and there was excess of serous fluid in the pericardium. The body was well nourished.

Further, I wish to explain my attitude in the matter. I have approached the subject with a perfectly open mind and before this Transvaal experience I had no special acquaintance with scurvy. After studying this outbreak I endeavoured to explain it by the current views as to the causation of the disease but failed. I am therefore venturing to submit this thesis to the judgment of the society. I would ask you to approach the subject *de novo*, with open minds, setting aside for the present all historical writings and sayings on the matter, treating this outbreak of the disease as an entity, and in particular bearing in mind the fact that the question of the antiscorbutic value of any food is not being raised. I propose to lay before you some evidence pointing to the fact that the condition known as scurvy in adults is not brought about by the absence of any particular kind of food from the dietary but is more probably a specific infection of bacterial origin.

Towards the close of the Boer war, in May, 1902, there was presented the unusual spectacle in the Transvaal and Orange River colonies of lands devastated by fire, devoid of farms, of crops, and of cattle, with the entire human population—natives and Europeans, combatants and non-combatants—gathered together into a series of small communities or units, of fixed location and definite occupation, under supreme military control. Each of these units was supplied by the military authorities with food, this food being mainly imported from over sea and transported up country along closely guarded railway tracks. Thus every individual in every community was definitely rationed. Except in the few towns that still remained undestroyed it was found impossible to obtain food of any description save that imported. For the inhabitants remaining in these undestroyed towns there were provision stores which supplied goods at fixed prices and in definite quantities only. The shops, the inhabitants, and their houses were under close military supervision by day and night. Solely for the use of the military classes there were instituted the field-force canteens which supplied additional articles of food on payment. These canteens, though private ventures, were also under military control, and the demand from them by the troops for goods was nearly always in excess of their power to supply. The goods sold at these canteens were principally imported preserved foods and thus all in British military employ were enabled in some measure to supplement their regular rations. All other classes were dependent entirely on the Government for rations; and about this period every individual in the country could, with some degree of certainty, be accounted for officially as to dwelling place, employment, and amount and nature of food consumed. From the military organisation of affairs and division of the inhabitants into units no individual non-combatant could fare better or worse in his food-supply than the remaining members of his own unit. Thus all burgher camp inhabitants participated equally in the general food supply for the burgher camp population and so with the natives attached to the British army and the regular European troops. For each of them as a class there was a definite food-supply per individual, based on the general stores of food in the country and issued under the control of the military authorities. Sometimes the burgher camp population fared better than the troops; at other times the positions were reversed.

The evidence supporting the contention that scurvy is caused by a specific infection is derived from two sources—viz., the study of the epidemic behaviour of the disease and the study of its clinical features. The incidence of scurvy in the Eastern Transvaal will be considered in the following units: (1) the burgher concentration camps; (2) the European soldiers; (3) African natives attached to the British army; and (4) African natives attached to the civilian Repatriation Department.

1. *The burgher concentration camps.*—The burgher camps under special observation were those situated at Middelberg, Standerton, and Volkrust. Each camp numbered about 5000 inhabitants, of whom 48 per cent. were children under 12 years of age. The remainder were classed as adults, male and female, and were in the proportion of 1 to 3. The inhabitants lived in tents which were regularly arranged at wide intervals on sloping, well-drained soil, and each camp possessed its own internal medical and educational organisations. Every camp was surrounded by barbed-wire fencing and was closely guarded, and as ingress and egress were privileges subject to military control each camp was in a sense an open prison. No food could reach the camps or be distributed to the inhabitants except with official sanction. A definite scale of food, varying with the age of the individual, was laid down and rigorously adhered to. In each camp were separate quarters for the native camp inhabitants. These natives, who likewise had fixed rations, acted chiefly as servants to the members of the camp staffs and to the Dutch inhabitants. They averaged 150 per 5000 whites.

The incidence of scurvy at the burgher camps, considered in detail, was as follows. In the camp at Standerton, between March, 1901, and January, 1903, there were no cases of scurvy. In the camp at Volkrust, similar in every respect to that at Standerton and over a similar period, there were no cases of scurvy. In the camp at Middelberg, which was slightly larger than that at Standerton, there were 100 cases among Europeans and one case among natives over a similar period. This outbreak of scurvy among adults at Middelberg, which occurred during December, 1901, and January, 1902, under a dietary similar in all respects to that in use at the camps at Standerton and Volkrust, immediately lends colour to the suggestion that the cause of scurvy is to be found in conditions other than those usually associated with food. The inhabitants of these camps had no occupation other than their domestic duties.

2. *The European soldiers.*—The district under inspection as to the prevalence of scurvy among Europeans in British military employ was that of Standerton. All the sick within a radius of 40 miles were received into No. 17 General Hospital. This hospital had advanced up country through Natal with General Buller's army, being known as No. 4 Stationary Hospital, and finally found a resting place at Standerton as No. 17 General Hospital. It comprised 600 beds for Europeans and a variable number—from 30 to 70—for natives in military employ. Between December, 1899, and January, 1903, 22,000 European patients were admitted. This number included 100 sick Boer prisoners of war, 40 sailors of the Royal Navy, and 160 civilians in Government employment. There was not a single case of scurvy among these admissions. Between March, 1902, and February, 1903, 3000 soldiers around Standerton were examined while at their duties and only one was found to be affected with scurvy. This was a private on detached duty, living with, and having charge of, the transport section of the Native Sanitary Corps, and to his case further reference will be made subsequently. Scurvy, therefore, with this single exception was non-existent among European troops and Europeans in military employ in and around Standerton.

3. *African natives attached to the British Army.*—With regard to the natives in military employ in and around Standerton the evidence is derived from two sources: the statistics of the native Military Hospital attached to No. 17 General Hospital and a repeated examination of the natives in military employ in the Standerton district. Examination of the hospital record of admissions of natives shows that

---

[1] A paper read before the Epidemiological Society of London on Feb. 19th, 1904.

the first case of scurvy admitted occurred in November, 1901. This was the first out of a total of 300 admissions for all causes. Among these 300, however, were 18 cases admitted for indefinite symptoms, such as debility, rheumatism, inflamed connective tissue, and periostitis. These may possibly have been cases of scurvy. No further cases of scurvy were admitted between November, 1901, and April, 1902. In May, the last month of the war, eight cases of scurvy were admitted, six from the Army Service Corps Transport Section on May 1st and two from the Sick Horse and Remount Depôts a few days later. In addition there were 27 cases, diagnosable by their symptoms only, of the character above mentioned. The total admissions to hospital from all causes between November, 1901, and May 31st, 1902, were 390. Definite scurvy, therefore, formed 2 per cent. of the total admissions and doubtful scurvy 7 per cent. Between June 1st and Sept. 30th, 1902, there were 193 admissions, including 22 cases of definite scurvy and 20 doubtful cases, i.e., 11 per cent. and 10 per cent. respectively of total admissions. The last period noted is from October, 1902, to February, 1903. The total admissions numbered 86. Of these, scurvy accounted for 24, and there was one doubtful case. Definite scurvy, therefore, formed 28½ per cent. of all cases admitted during this period.

The following is a summary of the foregoing facts. Between January, 1901, and February, 1903, 970 natives were admitted to the Military Hospital. Before May, 1902, definite scurvy was practically absent. During this month, after a total admission of 600 patients, eight definite cases of the disease occurred and were admitted to hospital. From this month onward until Feb. 7th, 1903, the prevalence of scurvy among the hospital admissions gradually increased from 2 per cent. to 28½ per cent. At the same time the total admissions for dysentery, diarrhœa, and enteric fever fell considerably and the monthly admissions fell from an average of 57 to 21. It is to be remarked that this notable increase in the percentage of admissions of scurvy cases occurred on the cessation of hostilities when the natives and troops to whom they were attached became stationary and concentrated in fixed camps in and around Standerton. It is of further importance to note that during the latter portion of the period under consideration when scurvy was most prevalent all restrictions in food had been withdrawn, and also all cases admitted came from units stationed in Standerton town.

Such is the information gleaned from the hospital statistics. The increasing proportion of scurvy cases admitted to the native military hospital led to a general inspection of all natives in military employ in and around Standerton. The men were examined in their own quarters while on duty. Outside Standerton, between March and July, 1902, before the troops and attached natives were concentrated in the towns, no signs of scurvy were found. After the concentration in Standerton natives were again examined and the following results obtained. Those inspected were of two classes, the labourers and the mule-drivers. The labourers were divided into the Native Labour Corps and the Native Sanitary Corps. In the Native Labour Corps there were 117 men employed and 16 per cent. were affected. In the Native Sanitary Corps 37 men were employed and 76 per cent. were affected. The mule-drivers were all attached nominally to regular regiments or corps. The following is a brief statement of the incidence of scurvy among them. Attached to pom-pom section, ten men; none affected. Attached to mounted troops, 67 men; 22 per cent. affected. Attached to Army Service Corps, Transport Section, 400 men; 32 per cent. affected. Detachment in charge of officers' carts, Army Service Corps, nine men; none affected. Detachment employed as police in Army Service Corps camp, eight men; four affected. To return to a consideration of the Native Labour Corps and the Native Sanitary Corps, these two units received exactly the same rations, which consisted of mealie meal 2¼ pounds daily and meat 1 pound weekly. The Native Labour Corps had 16 per cent. affected; their work was that of heavy goods porterage at the railway station. On the other hand, the Native Sanitary Corps had 76 per cent. affected and their work was that of gathering together the carcasses of animals that had died during the war around Standerton and burying them in pits. The eight men who were occupied in transporting the carcasses by mule wagons to the burial pits were every one of them affected with scurvy, as was also the European soldier in charge of this transport party. This is the case referred to previously as the only European found affected with scurvy at Standerton. His food was the same as that of the other soldiers at Standerton and was totally different from the food of the natives of the Native Sanitary Corps. Although he was granted the use of a separate tent, which stood side by side with those occupied by the Native Sanitary Corps natives, he, however, spent the whole of his leisure time with these natives and associated intimately with them. The natives of this corps had been recruited but three months previously, direct from their homes and had come in perfect health. It is a noteworthy fact that the head native of this gang occupied, with his family of six, a tent a short distance apart from the other natives and although their diet was similar to that of the corps none of them were affected with scurvy. The greater cleanliness of this head native's tent, as compared with the others, was also striking.

The marked contrast in the prevalence of scurvy in these two units—namely, 76 per cent. in the scavengers and 16 per cent. in the porters—under precisely the same dietary, again points to a factor other than food as the prime cause of the disease. Nor can that factor be entirely the unwholesomeness of the work of the Native Sanitary Corps because other diseases due to insanitary conditions, such as diarrhœa, were markedly absent. It may be further mentioned that although these two units, the scavengers and the porters, occupied separate quarters within a few hundred yards of one another, they were practically on one inclosed piece of land.

Next with regard to the mule drivers. Their food was exactly the same as that of the ordinary European soldiers with the exception of the lime juice ration. The cavalry, artillery, and pom-pom section natives lived in tents in the same camps as the European cavalry and artillery. Their surroundings were therefore comparatively cleanly and the incidence of scurvy varied from total absence in the pom-pom section to 22 per cent. in the cavalry natives. On the other hand, the natives of the Army Service Corps, who lived in a large encampment by themselves and whose tents were uncleanly and compared unfavourably with those of the cavalry and artillery natives, had 32 per cent. affected. Of the 400 men examined belonging to this division 200 were leaving for their homes on the following day, their contract period of service having expired. They complained of feeling too ill to work and refused to sign afresh any contracts for further employment. Quite one-half of this number were suffering from scurvy. It will be said, however, that the regular troops were supplied with lime-juice but not the natives. It may be pointed out, in return, that lime-juice was offered to all military natives in December, 1902, and the prevalence of scurvy was greatest in 1903. It must further be stated that the lime-juice was left severely alone by nine out of every ten men, troops and natives alike. This raw lime-juice was too acrid, too raw, and gave severe colic to many. It could not possibly be drunk without sugar and sugar was too valuable for other purposes to be taken to improve extremely unpalatable lime-juice. The ultimate result was that the natives attached to these corps and living with them had precisely the same dieting as the English troops. Still only the natives were found affected by scurvy and that corps of natives (the Army Service Corps) was most affected whose camp was most unclean and least under direct military supervision.

Here, again, proof seems to be wanting that the food factor is the cause of scurvy. In this connexion, further, the condition of affairs in the 19th Hussars is interesting. One squadron of the 670 Europeans forming the regiment were buying fresh vegetables regularly in addition to their ordinary rations. The remaining two squadrons subsisted on the rations issued; there was no sign of scurvy in either section.

4. *African natives attached to the civilian Repatriation Department.*—The last unit in which inquiry was made as to the incidence of scurvy comprised 900 natives of Africa employed as drivers and leaders of mules by the Repatriation Department—a civilian organisation inaugurated on the cessation of hostilities. The sick of this corps were treated at the hospital in the burgher camp, Standerton, when too ill to look after themselves; but when merely unable to work were kept in sick detention tents close by their regular quarters. Between August, 1902, and February, 1903, the department being in full working order, 50 cases of all diseases were admitted to the hospital. Of these 50—i.e., 62 per cent.—were cases of scurvy. In February, 1903, a final

inspection of the natives of this department was made. Of the 900 employed 500 were examined and 252 were found to be affected—i.e., 50 per cent. Of the 14 cases in hospital 12 were scurvy; of the 14 in the sick detention tents 12 were scurvy. In connexion with this inspection the diagnosis of the cases was confirmed by the senior medical officer of the burgher camp, Standerton (Dr. Alexander).

Again, the feature to be noted is that the food of these natives was quite as plentiful (in some respects more so) as that supplied to the natives under military control; but, on the other hand, their camp was the least tidy and cleanly of all at Standerton. The tents were overcrowded, closely packed together, and arranged with a total disregard for sanitation. The area of this camp, containing 900 men, was only one-third in extent of that occupied by the Scottish Rifles who numbered 500. The statistics of the sick in detention tents were not kept or the tale would have appeared heavier. Although the natives of the Repatriation Department did not outnumber by any means the natives in military employ the incidence of scurvy amongst them was the heaviest of all native units at Standerton. A consideration of this fact, then, that this body of natives with the best and most liberal food-supply in the town had the heaviest incidence of scurvy again points to the conclusion that food as a factor in the production of the disease must be eliminated.

Further evidence against food being the prime cause of the condition is afforded by clinical study of the cases—more especially by consideration of the mode of onset and the results of treatment. All these cases of scurvy commenced as an inflammation of the gums and the general symptoms followed at varying intervals but always secondarily to the gum condition. Improvement or the reverse followed *pari passu* with improvement or aggravation of the gum condition. This inflammation of the gums occurred in all cases without exception and in a definite manner. The process was as follows. Around the tooth and next to the gum was first noticed a collection of food. The gum edge nearest this aggregation soon became of a deeper red tint. This deeper tint area spread rapidly, but in the early stage was always separated from the healthy gum by a definite violet-mauve demarcation line. In a few days the whole of the gums, both internally and externally, became involved in the inflammatory process and areas devoid of teeth which had hitherto been healthy were now affected. At this stage the affected tissues were deep red in colour, soft, swollen, and compressible, tender, and bled easily on pressure. In a day or so the gums became easily separable from the teeth, and deep down, between the gums and the teeth, definite masses of a cream-cheesy consistency and colour could be seen and removed. These masses on microscopic examination were found to consist of pus cells, numerous micro-organisms of various kinds, and food débris. At this stage there were no constitutional symptoms nor could any changes be detected in the cardio-vascular system. These conditions developed later at varying intervals and it was found that they did not develop when means were adopted to improve the gum condition. Moreover, in cases in which the general disturbance was present there could be no ultimate recovery without a prior return of the gum condition to the normal. The method of treatment adopted, therefore, consisted of rest in the open air, isolation from previous surroundings, coupled with rigorous and frequent mouth antisepsis, care being taken to remove the cheesy masses mentioned above. The rate of general improvement and return of the gums to the normal condition was in direct proportion to the amount and efficiency of the antiseptic treatment employed for the mouth.

The fact that these cases when seen early could be completely cured by this treatment alone—with, be it noted, no alteration of any sort in the diet—argues directly against the diet being the prime cause of the condition. Further, the value of local treatment for the mouth condition is emphasised by a comparison of the results of treatment in advanced cases by (1) local *plus* constitutional treatment; and (2) by constitutional treatment alone. For local *plus* constitutional treatment the average length of residence in hospital was from 20 to 30 days, but for constitutional treatment alone it was from 60 to 90 days. It is also interesting to note that in advanced cases in which mouth antisepsis was employed there was little or no pyrexia, but that periods of pyrexia were a feature of similar cases in which this treatment was omitted.

These clinical facts, therefore, seem to suggest that the condition is not due to the food but is one caused by an infection through the gums and mouth. Whether the system is infected directly through the gums or through the swallowed saliva after the gum condition has developed cannot readily be determined.

Further, that the condition was found to prevail only among natives concentrated at Standerton, and then only in direct proportion to the absence of discipline and European habits of cleanliness, points to the fact that the unchecked habits of natives must in some measure either account for, or at least increase, the liability to the disease. The natives seldom used soap and rarely did they wash their hands or faces, and a large proportion, though they wore little or no clothing, were extremely verminous. This clothing was second-hand and usually consisted of one or more cast-off European garments which were very filthy and but seldom washed. They rarely washed their blankets and never swept out their tents. They had common eating and drinking utensils and frequently several ate out of one dish at the same time. Though dental caries is less common among them than among Europeans they rarely washed out their mouths. The majority of the natives chewed tobacco, "black cavendish" being easily obtainable through the troops, and not infrequently they passed the half-chewed "quids" from one to the other for further use. With this chewing there was expectoration free and plentiful—a habit found impossible to repress. Then they used mouth-organs and similar instruments in profusion, passing them from one to the other. They left both half eaten food and food in preparation lying about on the ground inside and outside their tents. Moreover, the tents were always in use and crowded during their off-duty time. Altogether these habits formed an excellent basis for the conveyance of any mouth-to-mouth infection.

To sum up—

1. The outbreak at the burgher camp, Middelberg, among Europeans and natives, was attributed to the nature of the food supplied. It was noticeable that the European sufferers consisted mainly of those persons who from advancing years were unable to fend for themselves, and of those who, suffering from mental depression at the prolonged separation from relatives, neglected to obey even the ordinary rules of personal cleanliness. Moreover, the cause could not have been in the food, seeing that food of precisely similar nature was in use at Standerton and Volkrust, and yet scurvy was entirely absent from these latter camps. But, on the other hand, the sanitary condition of the Middelberg camp was much inferior to that of the other camps named. At this time a determined effort was made to improve the sanitary condition of camps. Soap and fuel were ordered to be issued in unlimited quantities, whereas previously they had been supplied in restricted amounts. These articles were included in a new ration scale which was also introduced at this time. Scurvy now disappeared from Middelberg. It may be said that the cessation of the disease was due to the new diet provided, but the total absence of scurvy under the old dietary scale at Standerton and Volkrust is entirely opposed to this view, and it is remarkable that the disappearance of the disease was as markedly coincident with improved personal cleanliness in the Middelberg camp as with the change in diet.

2. Scurvy did not appear in the district of Standerton until the last month of the war when the mobile troops became stationary and concentrated into large units in the immediate neighbourhood of the town. Further, it continued with increasing severity among these units when war had ceased and when restrictions in the way of purchasing extra food had been withdrawn. After the war all classes were free to supplement their Government rations by purchasing fruit and vegetables at the various provision stores in the town. Special inquiry was made among those showing well-marked signs of the disease as to whether or no fresh fruit or fresh vegetables had formed part of their dietary in addition to the official supply of rations. In many cases there was abundant satisfactory evidence forthcoming to the effect that the sufferers were purchasing and consuming fresh pineapples, fresh bananas or fresh melons, and other vegetables imported direct from Natal. It is highly probable that these natives, whose daily pay always equalled and in many cases exceeded that of the English soldier, both purchased and consumed regularly a larger quantity of fresh vegetables or fruit than was the custom of our British European troops.

3. The only European affected at Standerton was attached to the Native Sanitary Corps—a unit of which 76 per cent. suffered from scurvy. Let it be noted, however, that this European lived with these natives. His diet was similar to that of the other European soldiers at Standerton, but he spent the whole of his time in the company of these scavengers and by reason of this mode of life was freely exposed to any mouth-to-mouth infection. On the other hand, the family of the head native, consisting of six individuals, was unaffected by scurvy. Their dietary was that of the Native Sanitary Corps, but they lived in a tent at a short distance from the scavengers' encampment and their standard of personal cleanliness was of a high order.

The varying incidence in the two units—the Native Labour Corps and the Native Sanitary Corps—namely, 16 per cent. in the former and 76 per cent. in the latter—cannot be explained by the food alone, since both units were on precisely the same diet.

4. With regard to the other natives inspected at Standerton not one of the 150 employed at the burgher camp as servants to the European camp staff was found to be affected, nor did natives employed as domestic servants in the European military messes, shops, or households in the town show signs of the disease; but in the remaining units, both civil and military, scurvy prevailed directly as the filthy habits of the natives were allowed to go unchecked by direct European control.

5. Of those sufferers from scurvy admitted to the military hospital at Standerton 12 per cent. died. Of those who recovered 90 per cent. returned to their former duties, their former dietaries, and their former surroundings; and though they lived among men afflicted with scurvy, yet the hospital records do not furnish a single instance of a patient once recovered from scurvy seeking readmission for a recurrence of the disease.

These facts, therefore, concerning the incidence of scurvy in the various bodies of individuals seem to be against the contention that food is the sole cause of the disease; and, moreover, the clinical facts also would seem to oppose the contention. The infection appears to occur through the mouth, the general system being involved later and secondarily. The manner in which the primary infection occurs and how it gives rise to the manifestations of the disease in the mouth are points on which it is not easy to make any definite statement and further investigation is required.

In conclusion, I submit that the facts adduced seem to prove that scurvy is not due to either the presence or absence of any particular kind of food from the dietary but rather to an infection for which food may act as a vehicle under conditions of dirty storage or dirty preparation; and considering that the disease prevailed in inverse proportion to the standard of personal hygiene of the individuals affected its infectivity would seem to depend on the insanitary habits and perhaps the unwholesome occupation of those who were its victims.

WEEKLY DIETARY SCALES AND INCIDENCE OF SCURVY.

A.—*In use at all Burgher Camps till Dec. 31st, 1901.*

salt, 4 oz.;

coffee, 3 oz;

Children (1–6 years).—Flour, 3½ lb. Remainder, as children (6–12 years).

Note.—When fresh meat served out—adults, 3 lb.; children, 2 lb. Tinned milk issued, "made up" by dispensers with water, ready for drinking, for children only, and issued daily but for adults only on medical officer's order. Wood and coal issued when required.

B.—*Introduced to all Burgher Camps Jan 1st, 1902.*

Age	Vegetables.	Flour.	Syrup or sugar.	Coffee.	Fresh meat.	Salt.	Milk.*	Rice	Soap.	Butter.

THE TREATMENT OF TABES DORSALIS AND ITS PROGNOSIS.

BY DR. MAURICE FAURE.

IT is an erroneous idea to consider tabes as a disease amenable to one method of treatment, that is to say, by drugs. Whether the drug be nitrate of silver, which was formerly employed, or mercury, which is employed nowadays, the idea remains the same and the object is to cure the patient by means of a drug. A nervous disease is not an equation in which the observer may set one poison as equally opposable to another poison. The evolution of tabes bears a definite relation to various infections and intoxications. The patient is always a complex problem and the physician must in every case take into consideration such causes as syphilis, overwork, alcoholism, tobacco poisoning, influenza, tuberculosis, and the like. On account of the predominant part played by syphilis in the pathogeny of tabes it is indisputable that antisyphilitic treatment ought always to be tried, at all events at the beginning of the attack, and especially if the tabetic patient have not previously undergone antisyphilitic treatment, but this treatment should not be kept up as a routine and particularly when it is observed to give bad results. Certain cases of syphilitic tabes which are vigorously treated with mercurials given in increasing doses from the beginning of their rapid evolution are often much improved and furnish the greater part of the cures

(Lemoine, Leredde), but the systematic giving of mercury or of iodides in big doses in those patients in whom tabetic lesions are already well marked, whose general health is broken down, and who are suffering from auto-infections arising from the gastro-intestinal tract, the bladder, or the lungs, does nothing except increase the number of poisons in an organism which is already overcharged with them, and as a consequence aggravates the nervous disorders which are the consequences of those poisons.

It is indisputable (1) that no tabetic gets well solely on account of the quantity of iodide or of mercury which he absorbs, and (2) that aggravation of the disease is more frequent among tabetics who are put on an antisyphilitic treatment in increasing doses than among those who are not treated in this way (Belugou, Faure). It is necessary to avoid attributing exclusively to the action of heroic remedies such as mercury the relaxations and the diminutions in the symptoms of disease which are sometimes observed in the majority of cases of tabes, for such ameliorations are the rule, and it is incorrect to say that locomotor ataxy must be a disease which is necessarily and invariably progressive (Brissaud, Joffroy, Raymond, Marie, Ballet, and others). The disease is steadily progressive in a third of the cases. It is arrested, improved, or gets well in about a fourth of the cases and in the remainder it proceeds very slowly with periods of quiescence only affecting the life of the patient seriously on occasions, and during the rest of his life offering him the possibility of living a life the activity of which doubtless must be diminished, but which is by no means very uncomfortable and is markedly different from the average life which used to be supposed to be the only one in view for a tabetic; and this life may go on for a long time, for by statistics collected at Berlin, La Malou, and Bicêtre it appears that the duration of life of a tabetic is very nearly the same as that of a normal patient (Leyden, Belugou, Faure, and P. Marie).

Why, then, are the present prognosis and that formerly held so different? For many reasons. First, it is obvious that in the present day nearly all medical men know how to diagnose tabes in its very early stages, whereas in former years the diagnosis was only very rarely made. As the patient is made the sooner aware of his malady by so much is he the sooner treated. Secondly, the very general employment of the treatment by mercurials and iodides of syphilitic patients is probably a reason for the diminution in the evolution of tabes which may be called the daughter or niece of syphilis (Babinski, Leredde). And thirdly, because a tabetic patient nowadays is treated as a tuberculous patient and so many other patients suffering from chronic diseases, so that he does not sit down with his hands folded and resign himself without a struggle to the fatal sentence which used to be pronounced against him as soon as the diagnosis of tabes was given. The tabetic takes care of himself, that is to say, just as a tuberculous patient does; he modifies his mode of life, he gives up certain periods to treatment, he regulates his affairs and no longer carries on his work as a normal man but as an invalid—in short, he makes terms with his enemy and sacrifices a little to gain much (*il fait la part du feu*). He lays down a special regimen for himself and so is enabled to economise his life, so to speak, and to make the smallest demands possible upon his vitality. The physician who undertakes the care of a tabetic patient should map out his code of directions so as to attain the mean between two extremes. (1) He must not allow the patient to think that there will be a complete and radical cure within a few months or that there is any specific remedy for his disease; but (2) he must not allow his patient to abandon himself to his lot as one without hope or to think that his disease is inevitably tending towards death, for such is not the case. The physician should further inform the patient that the disease from which he is suffering will in all probability not get any less during his life, that it will diminish his capacity for work, and will be the cause of suffering and of discomfort, but that on the other hand the watchful care of the medical attendant and the willing coöperation of the patient will to a great extent avoid the occurrence of possible complications. Finally, he must tell him that tabetic patients have been known to get quite well.

As a matter of fact, the arrest with the persistence of the abolition of the patellar reflex or of Argyll Robertson's sign, or of any other symptom without importance has the same value for the patient as a cure. Besides this the medical man must attend carefully to the state of the patient's bladder and see that it is washed out; he must prevent the accumulation of fæcal matter in the intestines which so commonly occurs in tabes; he must keep a watchful eye upon his patient's nourishment and sleep and see that he is not underfed and that he does not suffer from insomnia; he will order him to live as much as possible in the open air and will protect him from overwork, either mental or physical; and finally he will watch with care the condition of the circulatory system. By doing this the physician will be in the way to combat most of the causes of death which supervene in tabes. Moreover, while this long watch is being kept the physician must remember to order such drugs as may be suggested by circumstances.

The physician should besides impress upon his patient the necessity for taking an annual "cure" of one or more months' duration during which the patient residing in a sanatorium should devote himself entirely to the task of repairing the damage already caused by the disease and of putting himself into a condition to resist the attacks of complications which may be expected to occur. During this therapeutic retreat the patient should by means of special exercises learn how to train his respiratory system, as it is owing to defects in this that a tabetic patient suffers from respiratory crises, such as attacks of suffocation, of broncho-pulmonary infection, or of hæmoptysis. He must also train his excretory system so far as regards urination and defecation. He will also find that he will greatly improve and possibly will recover altogether his powers of voluntary movement over which he may have completely lost control. During the period of retreat he may also submit himself to a special hygienic course of thermal hydrotherapy, and finally must employ all the methods which experience has already shown to be useful in cases of tabes.

But the continuity of the treatment must be maintained not for a day, or a week, or a month, but throughout the years. After years of strict care and of watchful medical surveillance the tabetic patient will find himself a changed man. Even though he do not recover the integrity of all his functions yet he may at least make sure of the prolongation of his life, of being able to do some kind of work, and to have health and strength sufficient to enable him to lead a useful and interesting life. It is by following these directions that the physician will find himself in a position to give in a case of tabes a prognosis which, if not absolutely good, is yet quite bearable in the majority of cases.

Paris.

SEVEN CASES OF HOUR-GLASS CONTRACTION OF THE UTERUS.

By PERCY RENDALL, M.D. BRUX., M.R.C.S. ENG.,
HONORARY SURGEON TO THE EWELL AND EPSOM COTTAGE HOSPITAL.

THE following examples of hour-glass contraction of the uterus occurred in the last 200 cases of midwifery that I have attended.

CASE 1 (No. 58).—The patient was a middle-aged multipara. I was called in by a *confrère* when the child had been born five hours and the patient was much exhausted from loss of blood and prolonged manipulation. After examination I found that, with the exception of a small piece removed with the cord by forcible traction before my arrival, the placenta still remained in the upper portion of the uterus. Below this dilated upper third of the uterus was a firmly contracted ring of uterine muscle with an aperture of about one inch in diameter. Pressing the finger-tips of my right hand firmly together to form a cone I gradually forced them past the obstruction, then clenching my right fist I still further dilated the constricting part and after some manipulation managed to work round between the uterine walls and the remains of the placenta. This done the latter was easily removed and the left hand, which all the while had been grasping the fundus, then had no difficulty in inducing firm and general contraction of the womb. The lower two-thirds of the uterus had been the while in a complete state of inertia for my right hand and forearm had entered the uterus per vaginam as far as the elbow through a mass of jelly-like clots before I could reach the constricted orifice and the retained, though unattached, placenta. Friction of the fundus externally had been carried on intermittently, I believe, before I arrived, and the patient had lost a great deal of blood. An intra-uterine injection of hot water with permanganate of potass and a hypodermic injection of strychnine soon improved the pulse. Regular antiseptic douches were for the next ten days administered. This after-treatment was employed in all these cases.

CASE 2 (No. 116).—The patient, a very weak woman with her third child, miscarried at seven months after weeks of intermittent uterine hæmorrhage. The fœtus was born easily but immediately afterwards the uterus assumed a state of hour-glass contraction. With the left hand on the fundus the right hand was introduced as above described, and it was then found that the placenta was everywhere adherent above the contraction, and it had to be peeled off most carefully lobe by lobe; very little bleeding took place. I dared not give this patient an anæsthetic as her pulse was weak and intermittent. She made a good recovery. Her child was so weak and puny that he only breathed for a few hours.

CASE 3 (No. 134).—The patient, in her fifth confinement, showed a well-dilated os uteri, but the pains were ineffective and the head did not engage or descend. Forceps were therefore applied and grasping the head in its long axis I rotated and delivered it with ease, with the occiput anterior. The uterine inertia persisted after the removal of the child and an hour-glass contraction was discovered. The placenta, which was non-adherent, above the constriction, was removed as described in Case 1, with excellent after-results.

CASE 4 (No. 156).—The patient was a primipara, aged 42 years. Dilatation of the os uteri was very slow; the membranes, which contained a large quantity of greenish-black liquid, presented in front of the head and were mistaken by the nurse for a placenta prævia. After the child was born the uterine walls assumed the hour-glass condition. The woman engaged to nurse the patient was so ignorant, emotional, and deaf that I had to go out myself and secure a substitute during the first stage of labour. The patient weighed 16 stones, was the subject of chronic asthmatic bronchitis, and had a pulse so small and weak that I dared not administer an anæsthetic. Her only sister was an in-patient at a metropolitan asylum. As the patient throughout violently resented my manipulations the extraction of the placenta was very difficult, but eventually I succeeded. In spite of the complicating conditions she did well and her convalescence was uneventful.

CASE 5 (No. 169).—The patient was a healthy young primipara. The child was born naturally save for the fact that the cord was round the neck. An hour-glass contraction was noticed immediately after the birth. When the constriction was dilated the placenta, which was unattached, was easily removed and the patient made a good recovery. 12 months before delivery I saw numerous fibrous masses of any size up to that of a walnut which were discharged with the patient's menstrual flow on one occasion only. They might have been fleshy moles or masses of decolourised blood clot. I could detect no organised tissue.

CASE 6 (No. 189).—With her second child the patient showed an occipito-anterior presentation. The child was extracted with forceps under chloroform as the uterine contractions were futile in operation. Hour-glass contraction supervened on the birth of the child, but the non-adherent placenta was readily extracted. As in the foregoing cases the patient had no bad after-symptoms.

CASE 7 (No. 198).—The patient 14 months previously had miscarried at the fourth month. This labour was at term and with strong, steady pains the child appeared with the occiput anterior, the labour lasting four hours. After the birth of the child the fundus was felt so high up and so indefinite that the right hand was introduced into the uterus up to the elbow and an hour-glass contraction was discovered. The after-birth was lying loose in the upper third of the uterus and was retrieved in the way previously detailed. Recovery was in every way unexceptionable.

None of these placentas when examined showed any signs of morbid degeneration, nor was the cord attachment abnormal. Chloroform neither relaxed nor prevented the uterine band from contracting below the placental site. Matthews Duncan describes the condition "as one of uterine inertia both above and below the hour-glass contraction." Of this there can be no doubt, for although it is very often difficult to disengage the finger tips from the placenta and its membranes, which fall like a loose glove over them after they have overcome the hour-glass contraction, yet when once the fingers are completely disengaged it is found that there is plenty of room beyond the contraction—i.e., between the detached placenta and the upper inert uterine sac. From the cases above narrated it will be seen that, save in Case 1, no undue post-partum hæmorrhage occurred, as Simpson leads one to expect from this condition. Herman, who speaks of hour-glass contraction as "a rare condition," proceeds to suggest "that the circle of contraction is identical with the retraction ring or ring of Bandl." The illustration which he figures seems to point to the fact that perhaps the ring of Bandl is a synonym for the internal os. Playfair states "that this contraction is said to take place at the internal os." Clinically I have never been able to define the internal os during labour and when one's hand and arm enter a flaccid inert bag up to the elbow before reaching the constriction I can hardly believe that the inner os is so high. Rigby says that "the most frequent cause is over-anxiety to remove the placenta, the cord is frequently pulled at, and at length the os uteri is excited to contract." If, indeed, the uterus were not inverted by this procedure I think that Case 1 shows what would happen inevitably. Playfair also says "that if the *vis a tergo* was employed it would not happen but it is because the *vis a fronte* is used that these irregular and spasmodic contractions occur." Johnstone further "attributes the condition to the fact that ergot has been given before the expulsion of the placenta." But with the exception of Case 1 in all the above the *vis a tergo* was carefully and persistently employed, whilst no *vis a fronte* was used and ergot was not given in any of them until the uterus was completely emptied. Braun's sweeping assertion "that hour-glass contraction of the uterus is more frequently encountered in the experience of the young practitioner and diminishes in frequency in direct ratio to increasing years" seems hardly to account for such a definite condition.

Cases 3 and 6 showed obvious uterine inertia before delivery and made the use of forceps obligatory, so that it is not to be wondered at that this, another variety of uterine inertia, afterwards supervened, for I look upon the condition as an uncommon variety of uterine inertia. If the placenta is promptly extracted the irregular contractions can scarcely be regarded as more than an interesting feature, but when the condition is not recognised and treatment is delayed then the uterine sac is allowed to remain as two large flaccid bags, full of clots perhaps and with blood flowing or oozing from the placental site. The danger to the patient's life from this persistent inertia must be considerable, if not always immediate.

When the woman is lying in the usual obstetric position—on her left side—if hour-glass contraction supervenes the fundus lies high up in the left hypochondriac region of the abdomen and is hardly, or at most indistinctly, to be felt. These conditions are conveyed at once to the left hand which after the birth of the child ought never to leave the fundus till it yields a "cocoa-nut" sensation to the grip half way between the umbilicus and the pubes. When hour-glass contraction occurs the uterine cavity must be explored for the purpose of removing the after-birth, but with the proper use of disinfectants at the time and afterwards this manipulation should not give rise to any great danger. Chloroform should be given to mitigate pain if its use is not in any way contra-indicated.

The explanation of this abnormal muscular contraction of a section of the uterine walls seems to be that the womb is in full retraction and contraction to expel the child and when this has been accomplished it attempts afterwards to expel the placenta. But in a small proportion of cases the placenta cannot be at once detached by these muscular efforts from its uterine site and the retracting longitudinal muscular fibres, meeting with an unexpected resistance and exhausted by their recent prolonged efforts, relapse into a state of inertia. The circular fibres, however, below the placental site, acting simultaneously, find no resistance to their endeavours and contract firmly, and thereby exert perhaps an inhibitory action on the retractive longitudinal element below them—i.e., in the lower two-thirds of the uterine muscular walls.

Ewell, Surrey.

ROYAL UNITED HOSPITAL, BATH.—A cricket match, forming a continuation of the "Bath cricket week," was played at Bath on June 9th for the benefit of the Royal United Hospital. Both sides contained prominent members of the Somerset County Cricket Club and there was a large attendance.

cardiac sounds caused by the minute caverns of air in the tissues. 4. The diagnosis being made by the cutting out of the part played by the air by the various pressures of the stethoscope.

Camberwell, S.E.

AN ANALYSIS OF THE SYMPTOMS PRESENTED BY 132 CASES ASSOCIATED WITH THE PRESENCE OF ASCARIS LUMBRICOIDES.

BY WALTER H. HAW, M.R.C.S. ENG., L.S.A. LOND.

HAVING noticed a little time ago a correspondence in THE LANCET on "Fever due to Ascarides" I am led to hope that the following analysis of 132 cases, taken from my day-book and extending over a period of two years, may prove of interest to the profession. The symptoms refer to what was stated either by the parent or the patient or what was noted by myself. I do not wish it to be inferred that I ascribe every symptom to the presence of the worms; I merely am desirous of conveying that in 132 cases, where the ages ranged from eight months to 33 years, in which worms were present the accompanying symptoms were observed. They are put down in the order of frequency.

Fever was noticed 41 times (31 per cent.); vomiting, 38 times (28·8 per cent.); cough, 31 times (23·4 per cent.); abdominal pain, 29 times (21·9 per cent.); diarrhœa, 27 times (20·4 per cent); anorexia, 22 times (16·6 per cent.); restlessness, fretfulness, sleeplessness, night frights, and sleep-talking, 19 times (14·3 per cent.); rigidity of recti abdominis, 16 times (12·1 per cent.); emaciation, 14 times (10·6 per cent.); convulsions and nasal discharge, each 11 times (8·3 per cent.); constipation, 10 times (7·5 per cent.); cephalalgia, stomatitis, and pains in the limbs, each 9 times (6·8 per cent.); syncope, 8 times (6 per cent.); pallor, debility, and swollen hands or feet, each 6 times (4·5 per cent.); swollen face and nausea without vomiting, each 5 times (3·7 per cent.); delirium, 4 times (3 per cent.); swelling of the abdomen, mappy tongue, drowsiness, head sweats, pain in the chest, asthmatic attacks, and cold hands or limbs, each three times (2·2 per cent.); sweats, urticaria, eczema of the face, palpitation, crying fits, enlarged tongue papillæ, obstruction of the bowels, masses felt in the abdomen, and increased appetite, each twice (1·5 per cent.); while the following conditions were each noticed once (0·7 per cent.): jaundice, ascites, difficult micturition, nocturnal enuresis, erection of penis at the end of micturition, pains in the neck, fluttering before the eyes, photophobia, open-eyed sleep, sunken eyes, dark rings around the eyes, hysteria, trembling red fingers, decubitus on the knees and the hands, decubitus curled up, rigidity during sleep, and clonic spasms of the arms.

Knysna, Cape Colony.

A Mirror OF HOSPITAL PRACTICE, BRITISH AND FOREIGN.

> Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv., Proœmium.

HILLINGDON COTTAGE HOSPITAL.

A CASE OF TETANUS TREATED BY THE INJECTION OF ANTITOXIN.

(Under the care of Dr. A. CHARPENTIER.)

A MAN, aged 29 years, suffering from tetanus, was sent to the Hillingdon Cottage Hospital by Dr. P. J. A. Seccombe of West Drayton. On admission on the evening of May 21st the patient was found to be dull and apathetic; his pulse was 100 and his temperature was 101° F. He complained of pain and stiffness in the back and neck, all the limbs were rigid though not fixed, the mouth could only be opened about half an inch, and the risus sardonicus was commencing to show itself. He was sweating profusely and the perspiration smelt sour, resembling that of acute rheumatism. A wound of about the size of half-a-crown was seen over the left patella, with a black slough in the centre, which gave off the characteristic offensive smell of a tetanus culture. The pus from the wound, examined under the microscope, showed the bacilli of tetanus and large numbers of staphylococci. The patient stated that he had burnt himself three weeks ago but had been to work until two days before admission when he had begun to feel pain. Soon after admission the patient had a tetanic paroxysm and had difficulty in swallowing. He was given a mixture of chloral hydrate and bromide of potassium. The next day he was anæsthetised and the wound was freely excised, with all antiseptic precautions, and 70 cubic centimetres of antitoxin were injected under the skin of the abdomen. (As it was Sunday the special serum for intracerebral injection did not arrive until late.) In the evening there was still a good deal of rigidity and the patient had one other paroxysm but slept fairly well. Early in the morning of May 23rd the patient was anæsthetised and two cubic centimetres of antitoxin were injected into each side of the brain, according to the directions given by Dr. Borrel of Paris, Mr. H. Swithinbank of the Denham Research Laboratory having kindly lent Dr. Charpentier the trephine and syringe. 20 cubic centimetres more antitoxin were also injected under the skin of the abdomen. The patient recovered well from the anæsthetic. When seen in the afternoon the rigidity had passed off from the limbs and neck and the patient could open his mouth and put out his tongue when requested. At 7 P.M. the temperature was 102·4°, the pulse was 120, the respirations were 40, and he was evidently very ill, although he could answer questions and had free movements of his limbs. The knee reflex was normal. At 10 P.M. the temperature was 104·2°, the pulse was 120, and the respirations were 60. Cold sponging reduced the temperature to 102° again and he took nourishment well, but he died at 8.20 the next morning.

Remarks by Dr. CHARPENTIER.—The interest of this case lies in the fact that the tetanic symptoms entirely disappeared under the treatment. And I regard the case as one of "mixed infection"—that is, that he was infected with septicæmia as well as with tetanus at the same time. For (1) the film showed the presence of cocci as well as the bacilli of tetanus and (2) death was certainly not due to tetanus or to any interference with the brain by the operation. The statistics of tetanus treated without antitoxin give a fatality of 86 or 88 per cent., while Koehler states that cases treated by intracerebral injection of antitoxin show a fatality of only 30·4 per cent. There is reason to suppose that the early use of antitoxin in every case will ultimately give us results almost as good as those obtained by the early use of antitoxin in diphtheria; in any case there is no other treatment that has any effect on the disease and as the antitoxin does no harm it is certainly worth trying in all cases and if used early enough the results seem promising.

ROCHDALE INFIRMARY.

A CASE OF GASTROSTOMY FOR STRICTURE OF THE ŒSOPHAGUS.

(Under the care of Mr. WILLIAM POOLEY.)

IN April, 1903, the following case came under the care of Mr. Pooley. The patient was a woman, aged 43 years, suffering from inability to swallow. Diagnosis was made of cancer of the œsophagus and probably of the thyroid gland, with secondary implication of the lymphatic glands. On May 15th she was taken into the infirmary for operation. She was then very emaciated and suffering acutely from hunger and had also a troublesome cough and much salivation. For four days she was fed on nutrient enemas and gained strength. On the 19th Frank's gastrostomy was performed in two stages, the stomach being opened on the 20th, when the tube was inserted and feeding commenced and was well borne. The patient made an uninterrupted recovery, the temperature never rose above 99° F., and the pulse kept more or less normal and of good volume. The abdominal wounds were healed on the 29th and she went home on June 9th.

On July 7th she was readmitted suffering from dyspnœa, due to the pressure of the growth on the trachea. On the 10th tracheotomy was performed (the lower operation). Again she made a rapid recovery and was discharged on the 22nd She now gained weight and was able to attend to her children and household duties and Mr Pooley only called occasionally to see her, as the district nurses (Queen's Jubilee) went twice daily and attended to her tubes She continued free from pain, had a good appetite and was cheerful till towards the end of December when she began *to suffer from attacks of syncope She died on Jan 27th,* 1904, the end being hastened by the growth opening the vessels in the neck and causing profuse hæmorrhage The photograph which is reproduced was taken on Oct 31st, 1903 five and a half months after the first operation

---

PRETORIA HOSPITAL

A CASE OF RECOVERY AFTER OPERATION FOR PERFORATION IN ENTERIC FEVER

(Under the care of Dr GEORGE THORNTON and Dr A W SANDERS)

A MAN, aged 22 years, was admitted into the Pretoria Hospital on Feb 6th, 1904, with a history of severe headaches and general malaise for three days A positive diagnosis of enteric fever was made a few days later from the persistent fever, the occurrence of definite "spots," and a palpable spleen. The disease ran a mild course and by the middle of the third week the morning temperature was normal, the evening temperature was from 99 6° to 100° F, and the pulse was only from 72 to 76 On Feb 24th (the twenty first day of the disease) a change, however, occurred About two o clock in the afternoon the patient complained of colicky pain in the abdomen Some carminative was given and a hot water bottle was applied to the abdomen with apparent relief Shortly before 6 P M there was another attack of colic of much greater severity Dr Laing (assistant medical officer) was called He noted that though the temperature was only 97 6° the pulse was 100 and that the patient was looking anxious and was decidedly ill. Dr Thornton saw the patient with Dr Laing at 6 30 P M and distinct rigidity of the right rectus muscle and some tenderness in the right flank were found Palpation seemed to bring on spasms of pain which caused the patient to assume a decided "peritoneal" look The abdomen was not at all distended but was quite hollow as it had been for some time past The liver dulness was apparently normal The pulse, which had been only 72 at 2 P M, was now 116 although the temperature had fallen from 99 6° to 97 6° Dr Thornton and Dr Laing both came to the conclusion that perforation had occurred quite recently A *turpentine enema was ordered* and their surgical colleague Dr Sanders, was sent for with a view to operation if he agreed with the diagnosis The enema acted well Dr Sanders began the operation at 9 P M and the correctness of the diagnosis was soon established At the time of the operation the pulse rate had risen to 126 The *patient stood the operation very well* and on the next day his condition was excellent, his temperature was 99°, his pulse was 88, and there was no abdominal pain On the second day after the operation one grain doses of calomel were given every two hours for four doses followed by a one ounce dose of a saturated solution of magnesium sulphate The bowels had not acted by the next day and there were some distension and general abdominal discomfort, so two five grain doses of compound powder of elaterin were ordered to be given at four hours' interval That night the bowels were *moved freely to the great relief of the patient.* The next few days were uneventful and the patient made steady progress towards recovery Eight days after the operation however, the temperature began to rise again because of *the onset of a definite relapse which was attended by fresh crops of "spots" The relapse was of a mild type* and never caused any real anxiety although it ran a full three weeks' course On May 8th the patient was up and about and on ordinary diet.

Remarks by Dr THORNTON —The steadily increasing successful result to be obtained by surgical treatment of the above otherwise fatal complication is now well established The present case (the first successful one in South Africa) affords an example which it is hoped may be calculated to encourage others to adopt similar measures The following points of interest may be noted in connexion with the case the occurrence of perforation in a mild case apparently just about to enter on convalescence and exhibiting a clean tongue and a hollow abdomen, the premonitory signs of peritoneal pain and quickening of the pulse from 2 P M until actual *perforation* about 6 P M —"*preperforative stage*", the absence of any *apparent change in the liver dulness* after perforation and the explanation in the condition found on opening the abdomen—viz, a pinhole perforation practically sealed by inflammatory lymph, the steadily increasing pulse *rate along with a persistent subnormal temperature*—72 at 2 P M and 126 at the time of the operation (9 P M), and the production at so early a stage of the "peritoneal look on palpating the abdomen and its spontaneous occurrence also

No case could have been more hopeful and that recovery did occur is not surprising Unfortunately a similarly favourable condition is not always found even when an early diagnosis of perforation is made and an operation quickly resorted to We have had several cases operated on quite as early and have found a large perforation with a free escape of liquid *fæces* spreading widely amongst the intestinal coils In such cases I imagine that recovery is the exception Finally, I may be allowed to remark that in my opinion there ought to be no hesitation in giving aperients and if necessary stronger purgatives within two or three days of the operation if there be signs of increasing distension I believe the value of this is well recognised after laparotomy for other reasons

Remarks by Dr SANDERS —The successful issue of this case was, I believe, due to the attack being of a mild type the perforation speedily recognised, and an operation quickly resorted to Chloroform was given and a median incision was made The first coils of intestine seen appeared normal but on displacing these other coils were observed showing a general fine injection of their peritoneal coat and still later others with traces of inflammatory lymph adherent to them On *withdrawing a coil thus affected a portion* was soon found in which ulcers could be seen. One of these had extended through to the peritoneal coat and on its outer surface was some adherent lymph On removing this a fine perforation was seen from which bubbles of gas could be expressed A second ulcer also appeared nearly to have perforated Both ulcers were invaginated by pressing a probe over them in the long axis of the bowel and the edges of the groove thus formed were sewn together by several Lombert's sutures The peritoneal inflammation was fairly extensive but there was *little or no fluid between the intestinal* coils and there was no recognisable sign of any real fæcal contamination The affected area was well washed with hot *saline solution* and a counter opening was made in the right flank. A drainage tube was passed through this from the *abdominal incision* On the first two days after the operation [illegible] through this tube but as [illegible] ation was discontinued at [illegible] The wound healed quickly and well

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Protracted and Recrudescent Infection in Diphtheria and Scarlet Fever.

A MEETING of this society was held on June 14th, Sir R. DOUGLAS POWELL, Bart., the President, being in the chair.

Dr. ARTHUR NEWSHOLME read a paper on Protracted and Recrudescent Infection in Diphtheria and Scarlet Fever. He first detailed instances of cases of each of these diseases illustrating the occurrence of protracted or recrudescent infection in different circumstances: when there had been (*a*) contact or (*b*) no contact with other acute cases of the same disease; (*c*) when there had been several weeks' interval between the occurrence of the "return" case and the latest exposure of the infecting patient to the infection of other patients; and (*d*) when the patient had been treated alone at home. The various explanations of "return" cases were considered, including, besides the ordinary ones of failure of disinfection or a true "return" of infection, the possibility of a relapse of the original disease, of latent microbism, or of missed cases. Instances were given of diphtheria of infectivity continuing over 110 days or even longer. Instances of the somewhat neglected infectivity of ear discharges in diphtheria were given. The following considerations were emphasised: 1. "Return" cases are relatively rare and do not seriously invalidate the utility of isolation hospitals. 2. These cases occur generally, but not always, in connexion with rhinorrhœa and otorrhœa. 3. Accurate hospital records of complications are needed. 4. Post-isolation supervision of both home-treated and hospital-treated cases of scarlet fever and diphtheria is required. 5. The rhinorrhœa, which is the main index of protracted infectivity, is oftenest already present when isolation is commenced. 6. In some instances dormant infection is again roused into activity by catarrhs and the like. The close analogy between diphtheria and scarlet fever, as regards both protracted and recrudescent infection, was urged. The conception of protracted infection in diphtheria had been stated by Greenhow and Gresswell, but in scarlet fever it had not been recognised until recently. There could, however, be little doubt that it had occurred long before the period of isolation hospitals and that it explained the persistent belief in the infectiousness of late desquamation. The bearing of these considerations on the hospital treatment of these diseases was next discussed and the proposition was based on the foregoing facts that "in scarlet fever, as in diphtheria, the occasional persistence of infection is a phenomenon in the natural history of the disease, irrespective of, and in the main uninfluenced by, the external conditions to which patients are ordinarily subjected." This view was not, in Dr. Newsholme's opinion, contradicted by the apparent statistical excess of "return" cases in hospital experience. No statistics making due allowance for varying conditions of age and susceptibility had hitherto been made on a sufficiently large scale. The possibility of *non ceteris paribus* had not been borne in mind. It was reasonable to believe that the scarlatinal germs multiplying in the patient himself and collecting on the rhinorrhœal lesion with which the patient was usually admitted would be in large numbers and be more efficient to produce secondary infection than the relatively minute number that could obtain ingress from other patients. The notion that increased infectivity was caused by hospital aggregation was borrowed from the like theory for small-pox and in both instances was a theory to support a theory. The bearings of relapses of scarlet fever on this theory were discussed and the analogy of enteric fever, in which such relapses could not be caused by fresh external infection, was pointed out.

Dr. E. W. GOODALL said that he could cite many cases of protracted infection in diphtheria and scarlet fever and believed that it was well known that a patient who developed scarlet fever during convalescence from diphtheria was very liable to a relapse of his primary disease. He agreed that the protraction of infection was not due to hospitalism and that there were more instances of the kind in cases treated at home than was generally supposed. He laid stress on the part played by "secondary throats" as well as by mucous discharges in producing "return" cases and was of the opinion that desquamation was not a dangerous source of infection. Rhinorrhœa sometimes occurred for the first time after the patients had returned to their homes and in these cases was often responsible for the infection of others. It was not proved that complications in scarlet fever and diphtheria were more common in hospital than in private practice.

Dr. P. CALDWELL SMITH said that in his district he had had in 1902 4·5 per cent. and in 1903 6·5 per cent. of "return" cases and he believed that something would have to be done in order to reassure the public feeling in the matter.

Dr. W. J. R. SIMPSON did not agree with Dr. Newsholme that protracted infection was a part of the natural history of the pathology of these diseases. At a hospital in connexion with the Pasteur Institute in Paris patients suffering from various infectious fevers were separated in cubicles with glass partitions and one nurse attended several different cases, taking very careful measures in the way of disinfection. He was of the opinion that the ward system was in some degree responsible for "return" cases.

Dr. W. BUTLER did not think that hospitalism was alone responsible for "return" cases and stated that there was no evidence of medical men, nurses, or attendants carrying infection outside fever hospitals. He had had considerable experience of home-treated cases carrying infection for protracted periods and had found that convalescent homes to which only uncomplicated cases had been sent were as great, or greater, sources of secondary infection as hospitals where acute and complicated cases were aggregated.

Mr. D. L. THOMAS in investigating outbreaks of diphtheria for the late London School Board had come to the same conclusion as Dr. Newsholme as regards the part played by protracted infection and urged the more continuous supervision and bacteriological examination of cases.

Dr. C. K. BOND argued against the present hospital system but thought that the importance of "return" cases was exaggerated.

Dr. NEWSHOLME replied.

OPHTHALMOLOGICAL SOCIETY.

Primary Optic Atrophy due to Lead.—Optic Atrophy after Post partum Hæmorrhage.—Optic Glioma.—Microphthalmos.—Exhibition of Cases and Specimens.

AN ordinary meeting of this society was held on June 9th, Mr. JOHN TWEEDY, the President, being in the chair.

Mr. SIMEON SNELL (Sheffield) related a case of Primary Optic Atrophy due to Lead occurring in a boy aged 16 years. The sight had commenced to fail for rather more than a year before the patient was first seen in October, 1903, and had rapidly become worse during the past three months. The vision was: right, $\frac{2}{60}$; and left, $\frac{1}{60}$; both optic papillæ were white and atrophic but did not suggest preceding neuritis. The family and personal histories were good. For two or three years the boy had worked as a file-cutter which exposed him to the influence of lead and he had the ordinary symptoms of lead poisoning. The optic atrophy was, in Mr. Snell's opinion, due to this cause and all other causes had been eliminated. Mr. Snell, after mentioning a similar case, stated that among file-cutters he had observed several instances in which the optic nerves were affected either directly by the lead or in association with kidney or brain disease.

Mr. SNELL related the following case of Optic Atrophy after Post-partum Hæmorrhage in a woman, aged 28 years, who was seen last February a few days after recovery from puerperal mania. Both papillæ were atrophied but there was no evidence of past neuritis. There was no perception of light and the pupils were dilated and motionless. On Oct. 3rd, 1903, she was delivered of her first child at full term, but an hour afterwards she had hæmorrhage and although the amount lost was not very great yet she had never seemed really to have recovered from it. It was doubtful when the failure of sight had commenced but it had been suspected for some time. She had probably not seen at all for two months. There was no albumin nor throughout the pregnancy anything to suggest kidney disease. Mr. Snell referred to a previous case he had seen in which the sight was greatly affected by the same cause and he also alluded to cases collected by Chevallereau.

Mr. SNELL also narrated the following case of Optic Glioma. A baby, aged one year and ten months, was first seen on April 1st, 1897, when glioma of the retina was diagnosed. One eye was excised on April 7th and the tumour was found to be confined to the globe but was rather large. On Jan. 7th, 1899, the child was again seen with a similar condition in the other eye. This was excised on March 1st and at the present time the child was alive and well. Mr. Snell referred to the small number of cases in which both eyes had been removed for glioma without a fatal result. Other cases related were as follow. A girl, aged four and a half months, was sent to Mr. Snell on Dec. 18th, 1903, with glioma of the right eye; the eye was removed on Dec. 22nd and the growth found to be confined to the globe which it nearly filled; there was no recurrence. Another member of the same family had suffered from glioma of both eyes, which had proved fatal, the parents having refused to allow the removal of both eyes; there was one other child between these two who was alive and healthy. Mr. Snell mentioned that until recently no instances had been published in which glioma had occurred in more than one member of the same family. Up to the present time three observers besides himself had recorded cases.—The PRESIDENT, Mr. A. STANFORD MORTON, and Mr. C. DEVEREUX MARSHALL mentioned cases which they had seen of glioma bearing on the points brought forward by Mr. Snell.

Mr. M. STEPHEN MAYOU gave a lantern demonstration of the Anatomy of Three Cases of Microphthalmos which he had examined.

Cases and specimens were shown by Mr. LOUIS WERNER, Mr. E. E. HENDERSON, Mr. G. W. ROLL, Mr. E. W. BREWERTON, and Dr. RAYNER D. BATTEN.

EDINBURGH OBSTETRICAL SOCIETY.—A meeting of this society was held on June 8th, Dr. N. T. Brewis, the President, being in the chair.—Sir J. Halliday Croom read a [illegible] or Eclampsia with two cases. [illegible] he first to carry out Cæsarean [illegible] combined with contraction of the pelvis in the first degree and with a successful result. Sir Halliday Croom's first case was that of a primipara, aged 20 years. She had been well till the day previous to her admission into hospital when she suffered from slight headache; there was no appearance of œdema. On the day of admission she had vomited for some time and then frequent convulsions came on and she was in a comatose condition on [illegible] baths were [illegible] oroform was [illegible] lsions but it [illegible] albuminous. [illegible]

this offered the only hope for the woman and the best chance for the child. The operation was performed in the [illegible]

[illegible] had collected 28 cases o[illegible] more. [illegible] latter or[illegible] the forn[illegible] embered that only in the [illegible] [illegible] sarean section performed. [illegible] mortality was estimated variously from 3 to 25 per cent. and the infantile mortality from 25 to 54 per cent. Sir Halliday Croom then discussed the different theories of eclampsia, that of auto-intoxication, of uræmia, anæmia and œdema of the brain, pressure on the vessels of the renal system, acetonæmia, microbes, and hepato-toxæmia. The kidneys were mostly diseased; in 98 per cent. of the cases albumin was present in the urine. Recent experiments on animals had shown that the urine and serum of eclamptic women produced negative results. As regards treatment, owing to the special excitability of the nervous system in pregnant women any treatment that would anticipate, avoid, or shorten labour must be the best for the woman. The present knowledge of the causation and pathology of eclampsia was very unsatisfactory and could afford no reasonable basis for treatment. It was due to some toxic material in the blood and the great point was to favour the elimination of the poison; this was done by various means and the convulsions were controlled by chloroform, chloral, and morphine. The main point was rapid delivery. In the great majority of cases the fits ceased on delivery; therefore rapid delivery was desirable. There were four methods: Duhrssen's cervical incisions, dilatation by the dilators of Bossi and Fommer, vaginal Cæsarean section, and Cæsarean section proper. These were discussed in detail. Cæsarean section proper was justified in eclampsia mainly to save a living child, where the woman was in extreme peril and where it was probably impossible to deliver a living child through the natural passages.—The President, Dr. R. Jardine (Glasgow), Dr. D. Berry Hart, Dr. James Ritchie, Dr. J. W. Ballantyne, Dr. J. Haig Ferguson, Dr. J. Lamond Lackie, Dr. H. Oliphant Nicholson, and Dr. A. D. Webster made remarks on the paper and Sir Halliday Croom replied.—Dr. Hart read a note on Tubal Abortion. After pointing out that tubal abortion was one of the most frequent disturbances occurring in tubal gestation, he narrated two cases where he had operated for this condition. In the first the collapsed chorion was found in the pelvis and also a clot of the size and shape of a billiard ball evidently expelled from the tube. In the second case the patient had lost a large amount of blood and in the pavilion of the right tube he found the gestation, of the size of an egg, adherent all round, with about a [illegible] cavity. Blood had [illegible] towards the rectum [illegible] cavity. The tube wa[illegible] with iodoform gauze passing into the vagina. The patient, however, sank on the third day from anæmia and cardiac failure. He considered that in the production of tubal abortion there was, first, extravasation of blood between the gestation sac and its tubal attachment due to the phagocytic action of the trophoblast, and that the gestation itself became converted into a mole from blood extravasa[illegible] mnion and the chorion. The "mole," [illegible] hed and if the ostium abdominale was [illegible] be expelled by blood effusion and tubal [illegible] o the pelvis, producing complete tubal [illegible] e mechanism might account for incom[illegible] as in the second case, but possibly this [illegible] lly be an infundibular pregnancy simulating incomplete abortion.—Sir Halliday Croom, Dr. Ballantyne, and Dr. Haig Ferguson discussed the paper and Dr. Hart replied.—Professor J. A. C. Kynoch (Dundee) showed Two Vesical Calculi, the nuclei being formed by hair from a perforating dermoid tumour of the left ovary.

OTOLOGICAL SOCIETY OF THE UNITED KINGDOM.—The annual extra metropolitan meeting of this society was held at Glasgow on May 21st, Dr. Thomas Barr, the President, being in the chair.—An interesting demonstration on the Development of the Mastoid and the Tympanic Plate was given by Dr. J. Cleland, in the [illegible] he pointed out that, contrary to the [illegible] description, [illegible] stoid was no [illegible] ama. This [illegible] e suprameatal spine, and the so-called "squamo-mastoid suture" was formed by the entrance of a row of branches of the posterior auricular artery into the substance of the mastoid bone.—Notes of a case of Otitic Cerebellar Abscess, in which absence of the mastoid antrum from pathological changes was observed, were read by Dr. Peter McBride. Owing to an apparent improvement following the mastoid operation exploration of the brain was postponed. At the necropsy pus was found over the tegmen tympani and in the occipital lobe as well as in the cerebellum. The tympanic attic and aditus were present bey wash and change their clothes before they leave their work and go into the streets. Nothing like English working-class dirt is ever seen in public on the continent of Europe, unless in its far eastern portions; and dirt is prejudicial to health not only by its direct physical operation but in a still greater degree by reason of the absence of self-respect which it entails and which removes from the dirty man or woman at least one safeguard against drunkenness and against misconduct. Much of the dirt of the English labourer is at least partly due to his habit of dressing himself in a caricature of the clothes of the more leisured classes; and the introduction of the continental blouse would almost alone be sufficient to produce a beneficial change in his condition. Many of the reforms advocated by Mrs. Watt-Smyth are of a kind which could only be carried into effect by a combination of strenuous effort with improved legislation, but we think we could mention two for which the way is open. If the Local Government Board would secure fixity of tenure for medical officers of health the sanitation of the country would soon be enormously improved and the health of the poorer classes would be improved in a corresponding degree; and if the county councils throughout the kingdom would make proper use of the powers recently conferred upon them, and would see that the education of poor children, especially of girls, was of a kind calculated to be useful to them in after life, and not as useless as it has been hitherto, the axe would be laid to the root of many of the evils of which Mrs. Watt-Smyth has only too much reason to complain. While we cannot in all particulars agree with her we have no hesitation in commending her book to the careful consideration of all social reformers.

The Practice of Obstetrics. By J. CLIFTON EDGAR, Professor of Obstetrics and Clinical Midwifery in the Cornell University Medical College. With 1221 Illustrations, many of which are printed in Colours. London: Rebman, Limited. 1903. Pp. 1111. Price 30*s.*

THIS work is of a most ambitious character and does great credit to the industry of its author. Dr. Edgar's aim has been to present the "subject of midwifery from a practical and clinical standpoint, so that it will best facilitate the requirements of the student of medicine and the active obstetrician." Several innovations are to be found in the book. At the beginning of each part a table of contents has been placed and to insure ease of reference each part has been divided into sections, each of these in turn being headed with a table of its subject matter. In the section dealing with the subject of examination during pregnancy the various methods of carrying out pelvimetry are very fully discussed and a description is given of pelvigraphy or the method of taking a series of measurements of certain pelvic diameters and thus plotting out the size of the various pelvic planes. The interesting subject of cliseometry, or the method of measuring the size of the angle of inclination of the planes of the pelvic inlet and outlet, is also included and the apparatus devised by Neumann and Ehrenfest for carrying this out is figured and described. The various methods of practising cephalometry are given and, as Dr. Edgar points out, the late Professor Varnier succeeded in obtaining, after some three years of effort, a clear view by Roentgen-ray photography of the contour of the fœtal head in a woman seven months pregnant, so that he thought it would be possible by this means to determine the size of the fœtal head, its manner of engagement, its position, and its degree of flexion in the later months of pregnancy. It is greatly to be regretted that his death brought his studies on this subject to a premature conclusion.

The author has adopted a somewhat novel method in obtaining the illustrations for his sections on the mechanism of labour; those illustrating the engagement of the presenting part in the cervical canal were obtained by palpating with two fingers of the left hand and making a sketch with the right hand at the same time. He found that inspection was less satisfactory than palpation except in the case of face presentations. The illustrations of the engagement of the various parts of the fœtus in the vulva are drawn from flash-light photographs. An interesting feature in the work is the section devoted to the important question of the medico-legal aspects of obstetrics together with a chapter on Rape containing the results of examinations of 600 consecutive cases of this kind. It might be objected that such subjects are out of place in a text-book on Obstetric Medicine and if they had been inserted to the exclusion of more important matter no doubt such an objection would hold good but they have not been in this instance at any rate and after all the person most likely to be called upon for an expert opinion in a case of this kind is the obstetric physician. In discussing the important question of tubercle and pregnancy the author takes the view that pregnancy, even by itself, can render a healthy woman liable to become infected by the tubercle bacillus, and he argues that if this be admitted then the tendency will be much greater in the case of women predisposed to tubercle or who are or have been the subjects of latent tubercle or of apparent recovery from the disease. He would leave it for the future to decide whether pregnancy in the tuberculous woman should be interrupted as a routine procedure but he considers the prevailing tendency to persuade such women from marriage as serving in some measure to justify the interruption of a pregnancy which has already begun. It has been argued by some authorities that the induction of abortion in these cases is of no avail since the parturient patient is still more likely to succumb to the disease than if her pregnancy is allowed to continue, and while Dr. Edgar admits that the danger after delivery is undoubtedly very great yet he thinks that if the pregnancy is interrupted sufficiently early the result is likely to be good and the disease to be held in check to a decided extent. The question is one which certainly requires further consideration.

A very fair account of antenatal pathology is included and a section is devoted to the description of the various forms of fœtal monsters—decidedly a waste of space, we think.

The interesting subject of labour in elderly primiparæ is discussed at some length by the author. His observations have led him to the same conclusions as those of Courgenon of the Tarnier Clinic, that the influence of age on primiparity is that it slightly increases the length of the first stage of labour and that it somewhat increases the frequency of the indications for the use of forceps. Such conclusions are, of course, contrary to those held by the majority of authors and are in direct contradiction to the statistics published by some of the earlier observers. The subject is an important one in this age of late marriages and a low birth-rate, and the author's conclusion is no doubt the correct one—viz., that if labour is more severe or protracted in the elderly it is because of conditions which interfered with early marriage or conception. Dr. Edgar's writings on the subject of posture in obstetrics are well known and it is not surprising therefore to find that he has entered very fully into the matter and that the chapter is illustrated by some good reproductions of drawings.

While there is much in this book of great value we cannot by any means agree with all that the author either teaches or practises. For instance, we are told, in the treatment of placenta prævia occurring after the twenty-eighth week of pregnancy, that a case of this kind should never be left for natural expulsion of the child to occur after the performance of version—teaching with which we entirely disagree. The best results in the treatment of placenta prævia are to be obtained by t[illegible] immediate extraction of the child. A few pages before—viz., on p. 228—the author draws attention to the danger attending the practice of rapid delivery and yet he recommends it. In the consideration of the treatment of accidental hæmorrhage nothing is said of the method of employing a Champetier de Ribes bag in severe cases where the membranes are still unruptured and sufficient stress is not laid on the good results obtained by the Dublin School by their method of plugging the vagina for severe external hæmorrhage before rupture of the membranes. We notice one curious omission in the book—viz., there is no detailed account of hæmatoma of the vulva.

There is much that is of interest in this volume and while the general style is, perhaps, hardly clear and dogmatic enough for the student, it should be of value to the practitioner and obstetric physician. The illustrations—1221 in number—are well chosen and beautifully reproduced. The work will undoubtedly enhance the reputation of its author and is one which we can recommend.

A Method for the Identification of Pure Organic Compounds by a Systematic Analytical Procedure based on Physical Properties and Chemical Reactions. Vol. I. By SAMUEL PARSONS MULLIKEN, Ph.D., Instructor in Organic Chemistry and Organic Analysis at the Massachusetts Institute of Technology, Boston. London: Chapman and Hall, Limited; New York: John Wiley and Sons. 1904. Pp. 264. With three coloured standards. Price 21*s.*

IT is hardly possible to offer any criticism on a work such as this which deals so completely with constants and the physical behaviour and chemical reactions of compounds. The work is deserving of the highest praise and will occasion universal admiration for the monumental labour which its compilation must have entailed. The first volume contains classified descriptions of about 2300 of the more important compounds of carbon with hydrogen and with hydrogen and oxygen. The author's plan in the classification of compounds and in general analytical procedure is to arrange them in genera, orders, and various minor groups. This system is thus similar to that adopted in biology. It is necessary to understand the underlying principles of this classification before the general analytical scheme can be intelligently applied. The author calls the tests which have for their object the determination of the order of a species—that is, tests for the elements—ordinal tests. These are treated in Chapter II., which therefore relate to the detection in an organic compound of the elements carbon, hydrogen, sulphur, nitrogen, phosphorus, chlorine, bromine, and iodine. Again, he defines a genus as a group of species characterised by showing a common behaviour in certain prescribed and carefully defined generic tests which, with few exceptions, are based on chemical reactions rather than differences in physical properties. Generic tests are applied until the genus of the compound is ascertained. Aldehydes, for example, would give a colour reaction with a fuschine solution decolourised by sulphurous acid and carbohydrates would be tested for by the Molisch carbohydrate reaction which consists in adding to the substance a little water and two drops of a 10 per cent. chloroform solution of alpha naphthol. One cubic centimetre of concentrated sulphuric acid is then allowed to flow slowly into this mixture when, if a carbohydrate is present, a red ring will appear within a few seconds at the line of separation between the two layers. The colour is due to the formation of a furfural naphthol product. In this way the compounds are classified into the following genera: (1) aldehydes, (2) carbohydrates, (3) acids, (4) phenolic compounds, (5) esters, (6) acid anhydrides and lactones, (7) ketones, (8) alcohols and (9) hydrocarbons. Following the consideration of the compounds so [illegible], which is spread over 11 chapters of the book, comes the classification [illegible] Chapter XII. of Order 1 [illegible] hydrogen and of carbon, [illegible] concluding chapter (XIII.) [illegible] apparatus, and reagents are dealt with, and we have here an excellent illustration of the author's attention to detail and care in carrying out the tests. When it is considered that the physical constants of some 2000 compounds are given an idea of the enormous task of compilation will be gained. We understand that the second part of the work, which describes the compounds coming under Order 2 of the analytical system, is well advanced and finally it is proposed to issue a third volume which will provide for compounds of carbon with those elements which are not included in the first and second order. The author desires to base all the most essential portions of the descriptions of at least several hundred of the species of Order 2 on original or personally verified data and he appeals to those studying organic chemistry to cooperate in the work to the extent of placing at the author's disposal small samples of any of the less accessible nitrogen compounds which they may have prepared or collected. This work is clearly undertaken in the true spirit of one careful to a degree to place facts once and for all on record. We can think of no work of reference which can be more valuable to chemists and others engaged in the collateral sciences than that before us. The indexing is admirable and includes a formula group based upon the number of carbon atoms in the molecule of the compound. There is an excellent chapter on colour and the colour descriptions of the work are expressed in terms of the Bradley colour standard. This standard is printed on two cards placed in a pocket in the back cover of the volume. It contains 18 pure colours; and of derived tones there are 36 tints, 36 shades, and 12 medium "broken" colours. The volume is an excellent example of thorough, conscientious, and comprehensive work.

LIBRARY TABLE.

A Laboratory Manual of Physiological and Pathological Chemistry for Students in Medicine. By Dr. E. SALKOWSKI, translated by W. R. ORNDORFF, A.B., Ph.D. London: Chapman and Hall, Limited. New York: John Wiley and Sons. 1904. Pp. 265. Price 10*s.* 6*d.*—This is the authorised translation of the revised and enlarged edition of the work "Practicum der physiologischen und pathologischen Chemie," by Dr. Salkowski, professor in the University and director of the chemical laboratory of the Pathological Institute, Berlin. The translator, Dr. Orndorff, is professor of organic and physiological chemistry in Cornell University. This collaboration is sufficient to show the authoritative character of the work and the methods described bear evidence of a sound practical acquaintance with the details of laboratory manipulation. The book is essentially one for use in connexion with practical work at the bench. Its plan is quite simple, some 16 chapters dealing with the properties and examination of milk, blood, bile, urine, and food substances. Sections follow on quantitative analysis with simple examples, such as the determination of copper in copper sulphate, the estimation of aluminium in potash alum, and so on. Methods for the quantitative analysis of urine, fæces, milk, blood, and the gastric juice are next described. We find that the analytical processes are completely in accordance with modern investigations. The book will be a guide of undoubted practical value to the student in both the pathological and physiological laboratory.

A History of the Daubeny Laboratory, Magdalen College, Oxford. By R. T. GUNTHER, M.A., F.L.S., Fellow and Tutor of Magdalen College. London: Henry Frowde

Oxford University Press Warehouse. 1904. Pp. 137. Price 5*s.*—This is a very interesting monograph recounting the circumstances in which the Daubeny Laboratory at Magdalen College was founded. Dr. Daubeny, who had been Professor of Chemistry since 1822, was chosen in 1834 to succeed Sibthorpe as Sherardian Professor of Botany. Soon after this appointment Dr. Daubeny applied himself to make the study of botany and chemistry more efficient than hitherto. In 1848 he determined to erect a lecture room and laboratory close to the physic garden and the College gave him leave to do so, agreeing to allow to him and his heirs or assigns the sum of £282, "being a moiety of the sum proposed to be laid out by Dr. Daubeny, in case the society shall at any time hereafter within the period of 20 years find occasion or think it proper after six months' notice to resume the whole of the grounds into their own hands, but after that time the College shall have the option of assuming it without any payment." The laboratory still exists and many men of mark have worked within its precincts. Amongst them may be mentioned H. G. Madan, Wyndham Yule, Pike, Jeffrey, Burdon Sanderson, Gotch, Lazarus Fletcher, Harold Dixon, and Veley. We are glad to learn from the preface, writen by the president of Magdalen, that the subsequent history of the laboratory which Daubeny founded and to some extent endowed continues to be interesting. Moreover, "it has at times somewhat anticipated the university teaching" and "has afforded a home and opportunity for many stray professors and students and been the scene of not a little excellent original research." With certain of the latter we are acquainted and more especially with the researches of Professor Veley. We are sure that Mr. Günther's compilation will be keenly appreciated by Magdalen men. A list of the writings of Dr. Daubeny and a register of the names of those persons who attended the chemical lectures of Dr. Daubeny from 1822 to 1867 as well as of those who have received instruction in the laboratory up to the present time are appended.

Life of Joseph Jordan, Surgeon, and an Account of the Rise and Progress of Medical Schools in Manchester, with some Particulars of the Life of Dr. Edward Stephens. By F. W. Jordan, M.D. Durh. London and Manchester: Sherratt and Hughes. 1904. Pp. 135. Price 5*s.* net.—This book is dedicated to the memory of John Durham Bird, M.B., of Heaton Norris, partner and fast friend of the author. In putting forth this tribute of admiration for the originality, industry, and perseverance of a Manchester worthy whose great work was the germ of the provincial medical schools the author has been actuated by two motives—a desire to give to the present generation some idea of the early days of medical education in Manchester and a wish to place on record some particulars of the life of him who initiated it. The author was brought into frequent association with Mr. Jordan during the time that he was an apprentice to his nephew, James Stephens, and he has in his possession a number of papers written by Edward Stephens in 1859 for the purpose of supplying certain members of the House of Commons with the necessary information in their endeavour to obtain some mark of Her Majesty's favour for Mr. Jordan; he therefore felt himself specially qualified to undertake a work of this nature and he has received generous help from many sources. It was under the care of Mr. Simmons of Princess-street, a surgeon to the Manchester Infirmary, with whom he remained until he reached the age of 19 years, that Mr. Jordan laid the foundation of his abilities as a surgeon and anatomist. After completing his studies in Edinburgh under Sir Charles Bell and the celebrated Munro he joined the Royal Lancashire Militia, first as an ensign, in 1806, but as at this time there was a great demand for surgeons in the militia he became assistant surgeon to the battalion in the following year. In 1812 he was hard at work teaching anatomy in his "re-opened" school. In 1819, together with others, he established the Manchester and Salford Lock Hospital, to which he was appointed surgeon. In 1817 the Society of Apothecaries of London notified to Mr. Jordan that his certificate would in future be accepted by the board of examiners as in every way equivalent to those given by metropolitan teachers. This was a most important event in the history of the provincial medical schools. The medical student of the present day can hardly realise the difficulty in obtaining subjects for dissection in the days when, though a medical student was compelled to dissect in order to obtain his qualification to practise, the law stated that bodies should not be used for the purpose. The gruesome poem entitled "The Surgeon's Warning," which is reprinted in this book, will bring the whole state of affairs prior to the passing of the Anatomy Act vividly before the reader. The story of Mr. Jordan's election to the staff of the infirmary is graphically told. The excitement at the election was intense and resembled that of a parliamentary election. It cost Mr. Jordan £690. The expenses consisted chiefly in hiring vehicles to bring voters from the neighbouring towns. Mr. Jordan was a strong man with opinions based on what he had learnt in the school of experience. He was a good clinician, a cool operator, and was trusted and looked up to by the students as a sound teacher and a man of original thought. He was one of the founders of the Chetham Society in 1843 and of an antiquarian society called the Order of Rosicrucians or Brotherhood of the Holy Cross. This book contains the record of a singularly full life. Mr. Jordan's doings are certainly worthy of being enshrined in a volume such as has been produced by the author and we can recommend it for its style to those whom such works interest.

A Manual of Ambulance. By J. S. Riddell, C.M. Fifth edition. London: Charles Griffin and Co., Limited. Pp. 227. Price 4*s.*—We welcome another, the fifth, edition of this book, showing that it is in requisition, although the size and price place it beyond the use of the ordinary first-aid student. It is much to be desired that manuals intended for the use of first-aid students should be confined to giving enough knowledge to equip the student for his most useful work of rendering succour either in the street or the home. But we strongly deprecate the gradual increase in the size of these manuals due to the addition of matter quite outside the province of the first-aid student and encroaching upon the domain of the medical man. Nothing tends to do more harm to the "first-aid" movement than offering to unqualified and irresponsible persons knowledge more fitted to the medical student than to the first-aid pupil. It has the effect of alienating from this most useful work the members of the medical profession, and rightly so, if it tends in any way to trespass beyond the proper limits. In the removal of foreign bodies from the ear it would have been well to lay greater stress upon the danger of unqualified persons syringing the ear. A pea subjected to such treatment is sure to swell and it is in treatment such as this that the first-aid student is likely to do harm by adopting operative procedures which should only be conducted by the medical man. To the same category belongs the treatment of a fractured thigh by means of a long outside Liston splint. In a new edition which should be written up to date we should have expected to see the now most approved method for the first-aid treatment of a broken collar-bone. When the broad principle of never placing any bandage over the seat of fracture is wisely insisted upon, the application of the large arm-sling with the corner of the triangular bandage passing under the armpit instead of over the shoulder of the injured side is far superior, keeping as it does the pad in the axilla. Fracture near to or into the elbow-joint is also omitted with its required treatment by improvised rectangular splint. The chapter on Organisation and Management will be found very useful to secretaries intending to promote ambulance lectures but for the first-aid student himself we would recommend the smaller manuals issued by the London County Council or the St. John Ambulance Association.

Refrigeration in the Dairy. By Loudon M. Douglas, A.M.I.Mech.E. Putney: William Douglas and Sons. 1904. Pp. 80. Price 2*s.*—It is only within comparatively recent years that any serious attention has been paid to the construction of refrigerating machines and yet at the present time we depend largely upon the success of refrigerative processes for a very large proportion of our food-supply. Mention need only be made of the enormous supplies of frozen meat, fruit, and vegetables which annually reach these shores from New Zealand, Tasmania, and elsewhere. The work before us illustrates the importance of an installation of refrigerating apparatus in the dairy and the author has taken the opportunity thus presented to him of describing the refrigerative methods applicable to the dairy as well as to other operations. The *rationale* of the process on which mechanical cooling depends is explained and illustrations of various installations of refrigerating plant are given. There is little doubt that the time is at hand when every small dairy must be provided with refrigerating machinery and such apparatus is now made on quite a small scale. This book therefore will be of the greatest service to those engaged in the routine of the dairy.

Buddhism. An Illustrated Quarterly Review. Vol. I., No. 3. March, 1904. Rangoon: The Hanthwaddy Printing Works. Price 2 rupees—This is the official organ of the International Buddhist Society and contains articles on the ethics of religion, with special reference to the religious books of the East. An article on Hidden Tibet, illustrated with a reproduction of a photograph of the palace of the Dalai Lama, briefly reviews the work of the various explorers who have attempted to reach the "Forbidden City." Of special interest at the present moment is the statement: "In view of wild rumours to the contrary ...... Buddhists ...... view with absolute indifference the affairs of the Dalai Lama and of Tibet generally. ...... The fiction that Buddhists regard the former (the Dalai Lama) in the same light as do Roman Catholics the Pope is too absurd for serious discussion."

JOURNALS AND MAGAZINES.

Birmingham Medical Review.—The April and May numbers may be conveniently noticed together, as each of the articles which appear in the first of them is continued in the second. Sir Oliver Lodge contributes summaries of six lectures to medical practitioners on physics applied to medicine, "ethereal rays of all kinds" being the department of physics selected. The subjects considered at most length are the theories of electrons and ionisation, cathode rays, x rays, brush discharge, high-frequency oscillations, Leyden-jar discharge, ultra-violet rays, and radium emanations (i.e., alpha, beta, and gamma rays). Dr. William H. Wynn writes on Secondary Hypertrophic Osteo arthropathy, giving "a critical review of the whole subject"; the mere enumeration of recorded cases, together with the bibliographical references, fills 12 pages. Mr. Charles A. Leedham-Green records and discusses a great variety of experimental work on the sterilisation of the hands.

Dublin Journal of Medical Science.—The subjects or titles of the original articles in the June number are as follows:—Milk, Human and Bovine, by Dr. Walter G. Smith; concluding portion of the Clinical Report of the Rotunda Hospital, by Dr. R. D. Purefoy; and Traumatic Rupture of the Spleen followed by Recovery, by Dr. Percy N. Gerrard. In his paper on milk Dr. Smith confines himself to a consideration of its chemical and physical properties and to a discussion of some new and little-known reactions.

Journal of the Irish Medical Association.—In the June number the editorial article is a somewhat caustic criticism of the Irish Local Government Board Report for 1903. The annual report submitted at the general meeting of the association held on June 7th occupies several pages. The remaining contents include summaries of the business transacted at meetings of the council and the various branches.

The Electrical Engineer.—The issue of April 22nd devotes considerable space (about the equivalent of two pages of THE LANCET) to a supposed case in which an x-ray apparatus, in use in a hospital and at present worked by accumulators, may also be worked from the supply main which supplies alternate current at 110 volts and 76 periods. The first recommendation is rectification of the current by means of a Nodon valve with which a mercury interrupter or a step-down transformer would have to be used for the protection of the induction coil. Another method is the employment of an alternating-current motor direct-coupled to a continuous-current generator giving a current of about 10 ampères at 12 volts; this system has the advantage that it may be used for charging accumulators if the apparatus has to be taken from the hospital to a patient elsewhere. A third expedient might be stopping one half of each alternating wave with a Wehnelt brake and a "soupape." A variety of other suggestions are made, including the use of a Batten rectifier, of a Tesla transformer, and of a double-pole vacuum tube.

Mercy and Truth.—The June number contains an article on Work in Kirman, Persia, by Miss Winifred A. Westlake, L.R.C.P., L.R.C.S. Edin., and an account of a tour among the Bedouins in the wilderness of Beersheba, by the Rev. R. Sterling, M.B.

Knowledge and Scientific News.—In the June issue of this journal Mr. W. A. Shenstone, F.R.S., throws out the suggestion that radium may possibly be used to replace the comparatively complicated equipment required for x-ray photography. At present there is some difficulty in using radium in consequence of the radiations from the salt being too diffuse, but the article is illustrated by some very good reproductions of skiagrams taken by means of 50 milligrammes of highly purified radium bromide enclosed in glass tubes.

Analytical Records

FROM

THE LANCET LABORATORY.

(1) "TABLOID" CALOMEL AND OPIUM; AND (2) TABLOID ZINC VALERIANATE WITH IRON AND ARSENIC.

(BURROUGHS, WELLCOME, AND CO., SNOW HILL BUILDINGS, LONDON, E.C.)

1. THE combination of calomel and opium is classic and was, and is still, in favour in the treatment of inflammation. The tabloid of calomel and *opium* contains these drugs in exact doses and in a state of purity which are matters of some importance considering that this combination is frequently prescribed in intestinal disorders. From our examination of the tabloid there is no doubt that it speedily disintegrates after its administration. Each tabloid contains one grain of calomel and a half grain of powdered opium. 2. To the tabloid preparations of the valerianate series Messrs. Burroughs and

[illegible] formula: zinc valerianate, two grains; reduced iron, one grain; arsenious acid, $\frac{1}{30}$th grain; and extract of gentian, one grain. This combination has been favourably used in hysteria and in nervous affections associated with chlorosis.

CHLORYL ANÆSTHETIC (ABSOLUTE ETHYL CHLORIDE).

(DUNCAN, FLOCKHART AND CO., 143, FARRINGDON-ROAD, LONDON, E.C.)

Chloride of ethyl has been used with some success as a general anæsthetic, inducing narcosis when administered in quantities of from two to five cubic centimetres, the anæsthesia lasting for about one [illegible] be maintained for 10 or 15 minutes [illegible] administration of one or two cubic [illegible] sample submitted to us gave physical constants consistent with the statement that it is absolutely pure ethyl chloride. There was no residue on evaporation nor was any smell developed other than the fragrant chloroform-like smell of the pure chloride. The boiling point is 12·5° C. The anæsthetic is contained in cylinders holding 60 cubic centimetres graduated into one cubic centimetre divisions. The cylinder is provided with a stopcock by which any desired quantity of the anæsthetic can be discharged by gentle pressure with one finger. Ethyl chloride may thus be easily administered and the anæsthesia kept under control. Messrs. Duncan, Flockhart and Co. provide also the simplex inhaler for the administration of the chloryl anæsthetic. Its great merit is its simplicity as is pointed out in an article in THE LANCET of July 18th, 1903, p. 168.

BRANDIES.

(ROUYER, GUILLET, AND CO., COGNAC, AND 59, MARK-LANE, LONDON, E.C.)

We have received five samples of brandy from the above firm representing three qualities "offered as cognac" and "made entirely from Charente wine," while two samples are stated to be young brandies distilled entirely from French wines. We have no doubt that all the samples are genuine brandy—that is, spirit obtained in the pot still from grape wine. The following results on analysis were obtained: One star: alcohol, by weight 46·00 per cent., by volume 53·72 per cent., equal to proof spirit 94·14 per cent.; extractives, 1·16 per cent.; and fixed acids reckoned as tartaric acid, 0·015 per cent. The secondary products were found to be as follows, given in grammes per 100,000 parts of alcohol: acidity reckoned as acetic acid, 44·64; aldehyde, 26·41; furfural, 4·12; ether as ethyl acetate, 132·58; and higher alcohols, 223·20. Total secondary products, 430·95. Regarding ethers as a standard this brandy gives quite satisfactory results of analysis. It may be remarked that the furfural and the higher alcohols are somewhat in excess of the amounts commonly found in good standard Cognac brandy. The brandy is decidedly palatable. Two star: alcohol, by weight 46·68 per cent., by volume 54·43 per cent.; equal to proof spirit, 95·38 per cent.; extractives, 1·11 per cent.; mineral matter, 0·02 per cent.; and fixed acidity reckoned as acetic acid, 0·03 per [illegible] products were as follows, given agai[illegible] [illegible],000 parts of absolute alcohol present: [illegible] acetic acid, 10·8; aldehyde, 45·00; furfural, 3·60; ethers as ethyl acetate, 136·22; and higher alcohols, 180·00; total, 365·62. As regards ethers this specimen is also satisfactory. The acidity is somewhat low and the furfural is somewhat high, while the higher alcohols are about normal. We believe this to be a specimen of genuine brandy and its flavour is good. Three star: alcohol, by weight 45·55 per cent., by volume 53·24 per cent.; equal to proof spirit, 93·31 per cent.; extractives, 0·87 per cent.; mineral matter, 0·04 per cent.; and fixed acidity reckoned as tartaric acid, 0·02 per cent. The secondary products were as follows, given in grammes per 100,000 parts of absolute alcohol, acidity [illegible] 62·32; furfural, 3·10; ethers as ethyl acetate, 123·86; and higher alcohols, 224·40; total, 464·17. There is no evidence in the face of these figures that this is not also a sample of genuine brandy. It possesses a somewhat peculiar and full flavour in which the evidence of having been stored in wood is plainly indicated. Besides the foregoing samples we have received two samples representing brandies shipped in bulk. Their flavour is decidedly inferior, we think, to that of those just described, while on analysis they show a very high proportion of secondary products and in this regard they somewhat resemble marc brandies—i.e., spirit obtained from the marc or residue of grapes after most of the juice has been extracted. Thus the ethers amounted to over 200 parts per 100,000 parts of alcohol present. The higher alcohols were present in almost the same proportion.

NUTRIENT FOOD (SAVORD).

(SAVORY AND MOORE, LIMITED, 143, NEW BOND-STREET, LONDON, W.).

This food has been prepared with due regard to the requirements of those possessing feeble digestive functions. We find that its composition is accurately described. It [illegible] of milk in soluble form and carbo[illegible]y malting. For use the food is mixed [illegible]ked. On analysis we obtained the [illegible] moisture, 4·20 per cent.; mineral matter, 1·30 per cent.; fat, 2·00 per cent.; proteid, 26·46 per cent.; total sugar, 18·67 per cent.; and carbohydrates, 47·37 per cent. Except in regard to fat the food contains a satisfactory proportion of the elements of nutrition. The deficiency of fat, however, is compensated by preparing the food with milk.

EVAPORATED CREAM.

(FUSSELL AND CO., 4, MONUMENT-STREET, LONDON, E.C.)

Our analysis of this preparation was as follows: total solids, 40·00 per cent.; non-fatty solids, 28·78 per cent.; fat, 11·22 per cent.; and mineral matter, 2·21 per cent. This composition shows that the preparation consists of milk of good quality reduced to about one-third by evaporation. It is not correct to call it evaporated cream. According to analysis it is a poor cream but a rich milk. An important feature in regard to the supply of this preparation is that it may be obtained in what are called "family sized" tins which contain sufficient milk for use at one time so that none is left to deteriorate in the tin.

MALTICO PREPARATIONS.

(THE MALTICO FOOD CO., KINGSTON CROSS, PORTSMOUTH.)

We have already reported upon "maltico" which is described as an infant food and which consists chiefly of carbohydrates carefully modified by the diastasic action of active malt. The food is almost entirely soluble in water. It contains, however, only a small proportion of fat and therefore for infants it is desirable that it should be prepared with milk. A recent sample sent to us was found to contain 6 per cent. of fat, a result which is at variance with the statement that the proportion of fat in the new sample which we examined has been increased. On the other hand, "leci-maltico" yields 16·16 per cent. of fat due in part no doubt to the added lecithin. Leci-maltico is in fact an excellent preparation and represents a really valuable food. The value of lecithin in the treatment of anæmic conditions is well known. "Creamalto" is a combination of cream with active malt extract. The proportion of cream is indicated in the amount of fat, which on analysis we found to be 16·78 per cent. The preparation showed a decided digestive activity on starch. It should make a very excellent substitute for cod-liver oil and malt, while its flavour makes it much more pleasant to take.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AN ordinary meeting of the Council was held on June 9th, Mr. JOHN TWEEDY, the President, being in the chair.

It was resolved that diplomas of Fellowship should be issued to 16 candidates, two being postponed because the candidates were under age.

It was resolved that diplomas of the Licence in Dental

useum
of the
museum should be painted and that the museum should be closed during August and September to permit of the painting being done.

A report was read from the committee on the Relations of the Medical Profession to the Coroner's Court. It was approved and entered on the minutes. The committee had inquired into the matter and had examined the recommendations put forward by the British Medical Association and by the London County Council and had found ample proofs of the desirability of alterations in the present laws, but the questions involved are varied and include matters of administration, such as the rearrangement of coroners' districts, with which the medical profession is not immediately concerned. Having regard to the various interests concerned and to the failure of other institutions to induce the Government to initiate legislation, the committee was of opinion that it would not be expedient for t
in the matter at the present tin

The PRESIDENT laid before
had received from the Home
proposed to recommend Dr
St. Mary's Hospital as official
the vacancy occasioned by the resignation of Dr. A. P. Luff. The Council approved of the recommendation.

A letter was read from Mr. Henry Morris reporting the proceedings of the General Medical Council at its recent session. The thanks of the Council were given to Mr. Morris for this letter.

It was resolved that the revised regulations for study in chemistry and physics shall apply to those who register as
dental
student
of the

Third Examination—Midwifery: William Duncan, James Henry Targett, George Francis Blacker, and Arthur Hamilton Nicholson Lewers.

Examination in Public Health.—Part I.: Alexander G. R. Foulerton. Part II.: Herbert Timbrell Bulstrode.

In response to a letter from Sir R Douglas Powell, Bart., the Council granted permission to the Royal Medical and Chirurgical Society to hold a conversazione at the College in May, 1905, in connexion with the celebration of the centenary of the society.

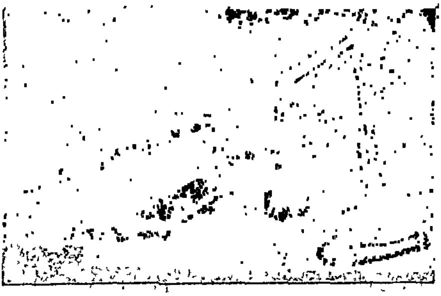
A vote of thanks was given to Mr. Thomas Bryant for his long and zealous services to the College as a member of the Council.

New Inventions.

A NEW CHLORIDE OF ETHYL INHALER.

THE accompanying illustration represents an inhaler for chloride of ethyl of my own design which I have used with marked success for the past 12 months. The following are some of the advantages which may be claimed for it: (1) direct and immediate contact with the chloride of ethyl vapour as there is no medium such as lint which is apt to get frozen and become inert; (2) a continuous discharge of a

necessity for measurement
ility of manipulation, as the
nd slipped on in a second or
two. A very short time is required for the induction of anæsthesia; the average time is 30 seconds and it may be as short as 15 seconds. The average period of available anæsthesia is one and a quarter minutes.



In administration the inhaler is placed firmly and closely over the patient's nose and mouth. (In dental cases a mouth prop or gag is placed in position before commencing.) The air valve is opened and two deep inspirations are allowed to fill the respiratory bag. The air valve is then closed and unconsciousness with full stertorous breathing will rapidly ensue. The inhaler is made by the Dental Manufacturing Company, 6 to 10, Lexington-street, London, W.

J. MAXWELL WOOD, M.B., C.M., L.D.S. Edin.

Dumfries.

DILAPIDATED RUSSIAN HOSPITAL BUILDINGS.—The *Russki Viedomosti* relates that in Juriev the public hospitals, pharmacies, and other analogous institutions are in a most dilapidated condition and in one of the hospitals the other day a large portion of the ceiling fell, simply through age, and killed a patient, wounding a nurse at the same time. It is stated that the fears for the safety of the other houses are based on bad material used in the buildings as well as on their age.

THE LANCET.

LONDON: SATURDAY, JUNE 18, 1904.

The Metric System in Medicine.

THE General Medical Council has passed resolutions which will be likely to create a certain degree of uneasiness amongst older members of the medical profession. The Council was asked by the Decimal Association to express its concurrence with the Weights and Measures (Metric System) Bill at present before Parliament and the matter having been referred to the Pharmacopœia Committee for an opinion it was mentioned in the report of that committee to the Council. The committee was strongly impressed with the importance of bringing the weights and measures of the British Pharmacopœia into accord with the international system which was current in the pharmacopœias of all other countries, and was therefore of opinion that the Council might properly use its influence in favour of the proposed legislation. The wording of the motion adopted by the Council will afford some comfort to those who might be disposed to view this proposal with distrust and uneasiness, since it clearly indicates that the change is only to be made after a sufficient period to be fixed by law. According to the terms of the Bill the substitution of standards of weight and measure according to the metric system for the existing imperial standards will not take effect earlier than the first day of April, 1909, so that there will be ample time for members of the medical profession to become acquainted with the changes which it involves. Should the Bill now before Parliament become law the Council expresses readiness to take all necessary steps to give effect to the law by making the proper modifications in the British Pharmacopœia. It will be remembered that when the Pharmacopœia was last revised in 1898 such a change was foreshadowed by the introduction of metric equivalents for the imperial weights and measures; this, at least, left to pharmaceutical chemists and manufacturers liberty of action and in no way interfered with the freedom of the prescriber. For doses the imperial system alone was used, hence in all probability most medical men ignored the columns of the metric system. The metric system, however, has numerous supporters and there is no doubt that it has much in its favour. Amongst modern physiologists and analytical chemists it is invariably employed, and its convenience for rapid calculations cannot be over-estimated; there is enormous advantage in adopting a system which is common to all nations, since the troublesome need of conversion is thus saved and this further diminishes risks of error. The one strong argument against the innovation is the convenience of the prescriber, and it is not the future or even the present student of medicine, but the practitioner who fears the change, feeling as if he were suddenly called upon to learn a new language. That this is no fanciful grievance has been suggested by experience in the United States where it has been urged that the unpopularity of the Pharmacopœia and its relative disuse may be attributed to the introduction of the metric system. Medical men are so much accustomed to regard the United States as the forerunner in modern improvements in pharmacy that it is interesting to learn that in this matter the departure has not proved a success.

There must be wholesale lightening of the ship by throwing overboard superfluous and antiquated cargo; the old comforting phrases about "putting everything right with a few grains of calomel or a grain or so of aloes" will have to be exchanged for a newer version. Revised versions are never satisfactory to those accustomed to an earlier form, even texts do not seem quite so soothing when amended by the latest scholarly efforts. We feel a sense of loss, although assured that greater accuracy implies gain. Patients then as well as the older generation of practitioners may be expected to resent any tampering with the standard and may feel as though landmarks were being shifted. Younger practitioners may also resent the change but will, it is to be hoped, not experience the same degree of difficulty in adopting the new and discarding the old. Those to whom the change will be most welcome are those still in the embryonic stage, who have not yet been troubled to commit doses to memory and thus have little or nothing to unlearn. The pity is that they will accept their inheritance of greater ease without one thought of gratitude, since they can never realise how much they have been spared. Every change of routine involves trouble and risk. In this suggested change the risk is more than merely the convenience of the prescriber. It is a trite saying that "coming events cast their shadows before them" and already, before the metric system has been officially recognised, we hear of trouble through the confusion of the two systems. Not very long ago we published an interesting case[1] in which most serious symptoms resulted from an overdose of hyoscine hydrobromate through the familiar mistake of dispensing grammes for grains; a dispenser sent a written message to a branch establishment for 0·08 gr. of hyoscine hydrobromate and the dispenser at the second shop, seeing decimals were used, took it for granted that it was a foreign prescription and that "gr." stood for gramme. In reporting this case it was remarked that surely the time had come for the rational and scientific metric system to be enforced as the official standard.

In the preface to the present Pharmacopœia it is recognised that during the period of transition from the imperial to the metric system a certain amount of confusion is likely to occur. We have become so much accustomed to think in terms of the imperial system that we feel as though we had, like the poet, "lisp'd in numbers, for the numbers came." Dread is experienced lest the attempt to make the change, with its appalling appearance of weird decimals, should involve personal risks to the patients and professional risks to the prescriber. All who have travelled on the continent know that these fears are more imaginary than real. The metric system is easy to acquire and it greatly facilitates rapidity of calculation. The Pharmacopœia Committee appears to consider that after the metric system has become the one legal system employed in this country it would probably still be necessary to insert, in reference to dosage at least, equivalents expressed in the old imperial terms. This may be desirable as a matter of convenience but it is to be hoped that it will not foster the continued employment of the older system. There is risk of confusion when the two systems are employed side by side and for this reason we think that if any change be made it should be a complete change; that the metric system, if legalised, should completely supersede the imperial system and that prescriptions should no longer be made up when the older system has been employed. This may seem rather a harsh recommendation but it is necessitated by a desire for the public safety.

[1] THE LANCET, Jan. 2nd, 1904, p. 24.

A Pathological Frontier.

WE have heard a good deal from time to time in connexion with the defence of our Indian possessions about a "scientific frontier" and a "natural frontier" but it has remained for the present expedition to Tibet to have added what may be not inappropriately termed a "pathological frontier" to the list. Our special correspondent in his "Notes from India" which we published at p. 1613 of our issue of June 4th gave us such a picture of the nature of the climate and country traversed and of the difficulties, hardships, and sufferings of the Tibet mission on its march as may well keep Russia from caring to encounter them by advancing *viâ Tibet into* India, if she ever cherished such a design. Our correspondent says that the ordinary accounts of the advance of the Tibet mission only briefly refer to some of the hardships of this wintry march. But it is not generally recognised that the marching and camping are being done at altitudes unknown and impossible in Europe and that while the suffering from the cold is severe that from the rarity of the air is intense. To quote from our correspondent's communication, "The lungs seem unable to do their work. One gasps and pants after the slightest exertion as if about to suffocate. Whilst still this rarefied air can be tolerated but under exertion air-hunger becomes distressing. The transport animals feel it and the business of bringing them along is painful. The mission camped at Dantu opposite a frozen waterfall 200 feet high. As the march was above the wood line fuel was doled out very sparingly—in fact, only sufficient to cook the daily ration. None could be spared to light fires for the sake of warmth. Further on Pharo plain an altitude of 14,000 feet was attained. During this part of the march it is stated that at every few yards men sat down, bent double, grasping their heads in their hands." Still further on came the Tung pass which is higher than Mont Blanc and the air-hunger became still more extreme. Many followers in advancing lay down and would have died in the cold but the column moved them on to another camping ground, but without fuel and with 23° of frost.

The difficulties of this particular march in many ways may be said to have been unparalleled but a reference to the published accounts of other exploratory missions undertaken on behalf of the Government of India furnishes us with somewhat similar experiences. In "The Roof of the World," published in 1876, Colonel T. E. GORDON, now General Sir T. E. GORDON, K.C.B., has given a full description of his journey and experiences on the Kashghar Embassy of 1873–74 under the late Sir DOUGLAS FORSYTH, K.C.S.I. The mission was a very remarkable one in many respects, especially as regards the exceptional altitude of some of the mountain passes traversed—18,550 feet in some instances. Mountain sickness was very prevalent but it appeared to be like sea-sickness in that it seems possible to get used to it, as it became less and less at each succeeding elevation. Headache, breathlessness, and difficult respiration are also mentioned. The mission had a native butler who was as sensitive in these respects as a mountain barometer at all altitudes at and above 1200 feet. On the return journey Dr. F. STOLICZKA, Ph.D., of the Indian Geological Survey, a member of the mission, died at the Dipsang plateau, where the climatic conditions proved distressing and the elevation was 17,500 feet; otherwise the mission was healthy. It may be mentioned that while the temperature was 15°F. below zero in tents at Aktagh the thermometer marked 100° in tents at Rawal Pindi when the mission reached there towards the end of July.

The late Surgeon-Major BELLEW, C.S.I., of the Bengal Staff Corps, in his "Kashmir and Kashghar, a Narrative of the Journey of the Embassy to Kashghar in 1873–74," published in 1875, deals more fully, as might be expected, with the medical aspects and occurrences of the journey. He dwells upon the effects of elevation in causing distressing headache, giddiness, nausea, and sickness, as well as difficulty of breathing, especially on exertion, all of which he attributes to an imperfectly oxygenated blood from rarefaction of the air—"the evils of a half ration of our wonted supply of oxygen." He mentions that he found the administration of chlorate of potassium as a means of introducing oxygen into the blood of great value in mitigating these distressing symptoms—a suggestion which he obtained and acted upon from Dr. G. HENDERSON'S experience on his journey in the same regions in 1870. At 18,300 feet men and cattle were severely affected by the elevation and cold, animals labouring and moving slowly with light loads and some of them being affected with great muscular tremor and tumultuous action of the heart. All these experiences of the difficulty of traversing long distances at high altitude justify us in regarding the enormously elevated ridges and plateaux of Tibet as a "pathological frontier."

On the Immunity from Plague enjoyed by Shanghai.

WE have had our attention drawn to the immunity enjoyed by Shanghai from plague whilst so many of the other coast ports of China suffer severely. Various explanations have been offered for this fortunate state of affairs, and, were we convinced of their potency, we would suggest that strict inquiry should be made into the matter with a view of ascertaining how Shanghai has remained unaffected, and what practical lessons are to be learned from the circumstance. The immunity is ascribed to (1) the strict inspection of ships calling at the port from infected centres; (2) the excellence of the main drainage of Shanghai; (3) the fact that the Chinese houses are two-storeyed buildings only and that each house has a small yard at the back paved with cement or concrete; (4) the absence of sanitary fittings inside the houses, so that it is impossible for the Chinese to interfere with the working of the drains; (5) an ample supply of water; (6) the removal of the whole of the night soil and kitchen refuse by the bucket system; and (7) the flushing of the drains by tidal water and the consequent destruction of rats. According to this showing Shanghai would appear to be a hygienic paradise and immunity from epidemics of all sorts practically to be guaranteed.

Those who know Shanghai will be astonished to hear the sanitary arrangements of the city so highly spoken of. It is a fact that typhoid fever is present in Shanghai to a degree unparalleled in any other of the coast ports of China—at any rate, so far as Europeans are concerned. Dysentery is a disease of common occurrence, diphtheria claims its victims, and cholera is not unknown during the autumn. The water-supply of the city is, moreover, not above suspicion. Water there is, no doubt, in plenty but the quality of the water was recently the subject of serious alarm. The claims made for the bucket system being efficacious in the prevention of plague cannot be seriously considered, for the bucket system is in force in all treaty ports in China. It would appear, therefore, that there must be other causes at work to account for the immunity enjoyed by Shanghai but we are not prepared to say what these are. In many other parts of the world we find isolated towns and districts with a similar and a still more extraordinary immunity. No better example can be quoted than that of the city of Madras. Plague has not visited Madras city although in the Madras Presidency right up to the very outskirts of the city itself plague has prevailed in epidemic form for several years. Anyone who has visited Madras is ready to believe that all the elements, as we at present understand them, calculated to harbour plague exist there, and yet, although some cases of the disease have actually been imported into the town and died there, the disease has not spread. Why this should be is not understood. Calcutta, again, has not suffered so severely as Bombay, although the conditions would appear to be even more favourable for the spread of plague in the former than in the latter city. There are other etiological factors at work that are not readily ascertainable and the immunity of Shanghai is not to be understood by any sanitary consideration which we know of. In Hong-Kong we have the example of a city visited again and again by plague, a city in which the quality of the water supplied for consumption is amongst the purest in the world. The bucket system is in force there, the sewerage is excellent, and yet Hong-Kong suffers to as great an extent as Canton where all the sanitary conditions are bad.

The fact is that plague exists nowhere along the valley of the Yang-tse-Kiang and although Shanghai stands at the mouth of the river and is liable to infection from the seaboard we know that, in China at any rate, the infection has come for the most part overland. Canton was infected from Yunnan and from Canton plague reached Hong-Kong. The disease travelled along the Chinese littoral to Swatow and further north. The infection of Niu-Chwang and parts of Manchuria was possibly from up country, for CLEMOW has shown that a distinct centre of plague exists to the north of the Great Wall. These and other considerations render the immunity enjoyed by Shanghai difficult to be accounted for in any sanitary conclusions. We are daily getting additional proofs that the presence of plague in epidemic form is dependent upon the infection of the domestic animals of the district. Cases of plague occurring amongst men arriving from infected areas are little likely to lead to a local outbreak of the disease. It seems to be a fact that if the animals do not suffer from plague the disease will not spread amongst men. By animals it is not only rats that are meant for almost all domestic animals are known to acquire plague and it may be safely said that if these animals do not develop plague the disease in man will not continue in any particular district. We rejoice to know that Shanghai has escaped plague so far; we are willing to admit that careful precautions have been taken by the municipal authorities; we admire the sanitary improvements which have been accomplished by the untiring efforts of the medical officer of health, the sanitary engineers, and by those responsible for the health of the great city, of which the foreign community has every reason to be proud; but we are sure that they will pardon us if we refuse to recognise as a scientifically proved fact that these measures have succeeded in protecting Shanghai from an epidemic of plague, seeing that other cities and districts with far fewer hygienic advantages have also shown an extraordinary immunity to the same disease.

Annotations.

"Ne quid nimis."

PUBLIC COMPETITION IN THE SERVICE OF HUMANITY.

ANY plan which is calculated to develop inventive capacity and to direct it towards the attainment of humane ends is worthy of the highest encouragement. The great masses of people must include not a few individuals possessing originality of purpose, thought, and practical application to a special degree which lie dormant for the want of a stimulus or for lack of opportunity of developing these attributes. There is no doubt that if many of the difficult problems which frequently confront us could be forced upon the serious attention of the public at large there probably would be found some individuals to whom a satisfactory way out would readily suggest itself. Amongst the methods of drawing upon the talent that may otherwise lie hidden in a community is that of offering prizes of a substantial and honour-giving character. The method is commendable so long as the reward is ample to the originator of the design and consistent with what may prove to be its practical value to humanity. There are several instances on record in which by opening a public competition and offering substantial money prizes valuable results in the interests of humanity have been gained. We need refer only to two—viz., the King's Prize Essay for the best design of a sanatorium for the treatment of consumption and the Nobel prize for the best essay on the steps to be taken calculated best to secure the peace of the world. The latest example of inventive capacity being invited and encouraged to work in the interests of humanity was the offer of the Transvaal Chamber of Mines at Johannesburg in 1902 of three prizes—the first of £500, with a gold medal, the second of £250, and the third of £100—for the three this fearful scourge and great good has come out of the scheme. Even assuming that an entirely satisfactory method does not prove to be the outcome of a competition organised on the lines indicated, yet the efforts made towards securing a desirable end are not likely to be made in vain but rather to add very substantially to our

use of an atomiser. The first prize was awarded to Mr. Thomas J. Bri
75 per cent. o
for a water dr
desired, but it
the drill will lead inventors to improve further upon it until absolute success is attained.

THE MINOR NEUROSES AND PSYCHOSES AS SEEN IN THE DISPENSARY PRACTICE OF A GREAT CITY.

IT is seldom possible to obtain accurate data and trustworthy figures with regard to the distribution of the minor psychoses and neuroses in any community, though the inquiry might be well undertaken by philanthropic bodies such as the charity organisation societies of great cities. In the *Journal of Nervous and Mental Disease* for May Dr. Smith Ely Jelliffe of New York gives an interesting account of the cases of minor neuroses and psychoses at the Vanderbilt Clinic of New York since its opening in 1888, and adds full details of the special kinds and classes of patients treated during the past year. The conclusions drawn, based as they are on the material of a vast and representative practice of the dispensary class, are of both medical and social interest. During the early years of the period—viz., from 1888 to 1892—the cases of all diseases treated in the clinic averaged from 30,000 to 35,000 a year, the proportion of nervous diseases among these being between 4 and 5 per cent. This proportion has been maintained throughout the period under review. During the past five years the cases of all diseases treated in the clinic averaged from 46,000 to 48,000 per annum, the proportion of nervous diseases remaining practically as before—viz., between 4 2 and 4 8 per cent. "So far as the Vanderbilt Clinic is concerned," says Dr. Jelliffe, "the ratio of sickness referable to the nervous

entire sick
those with
tended with
ound that in

and of "obsessions" were very rare (three cases in all).

morphine,
(five cases), paranoia
ven cases), and melancholia with
cases). The cases of melancholia were sufficiently severe to warrant the diagnosis. The psychoses which follow were in higher proportion—viz., 28 cases of climacteric psychoses or mental disturbances in women occurring at the menopause and sufficiently grave to cause anxiety to themselves or their friends, 26 cases of general paralysis of the insane, all in males, and 40 cases of chronic alcoholism of who 39 were males. Probably, says Dr. Jelliffe, these alcoholic cases represent but a small portion of those addicted to excessive drinking. On the borderland between the psychoses proper, as mentioned before, and the neuroses a number of cases variously called neurasthenia and phrenasthenia were treated at the clinic. Whether the "neurastheniacs" that present them

to decide, Dr. Jelliffe's opinion being that most of the cases were "individuals of weak mental capacity and, properly speaking, psychasthenias rather than neurasthenias of the strictly nerve-fatigue type. Neurasthenias of defective [cerebral] evolution perhaps they may be but neurasthenias of overwork they rarely are." They comprised 364 patients, of whom 211 were men and 153 were women. No etiological factors are mentioned for nearly the whole number, except that syphilis is put down as an exciting cause in six, trauma in two, and sexual excesses in 45. It appeared that most of them were of congenitally abnormal nervous constitution. The group of "neuroses" proper which follow comprised varying forms of neuralgia and neuritis, of peripheral palsies, tabes dorsalis, and other diseases of the nervous system. Cases of neuralgia were common, there being 114 cases, including 49 males and 65 females. The neuralgic attacks were nearly always local, affecting the following regions—viz., facial (40 cases), occipital (five cases), sciatic (36 cases), supraorbital (nine cases), dental (16 cases), brachial (nine cases), arthritic (ten cases), and lumbar region (four cases), while a few are not specified. Neuritis affected 61 patients—viz., 35 males and 26 females. All were mild cases unassociated with peripheral palsy or wasting of muscles. They comprised three cases of occipital neuritis, four due to lead poisoning, eight of multiple (peripheral) distribution and of obscure causation, and ten of alcoholic neuritis. The peripheral palsies and organic

cases of tumour of the spinal cord, six of lateral sclerosis (all males), 16 of disseminated sclerosis, 20 of Erb's paralysis, 21 of acute anterior poliomyelitis (of children), 31 of traumatic palsy of various nerves (21 being of the musculo spiral nerve), 31 were cases of facial paralysis, and 35 of tabes dorsalis.

THE LIVERPOOL SCHOOL OF TROPICAL MEDICINE AND TRYPANOSOMIASIS.

IN a letter published in the *Times* on June 14th an appeal is made for funds to continue the important researches on trypanosomiasis which are now being conducted by the Liverpool School of Tropical Medicine. In the appeal, which is signed by Sir Alfred L. Jones as chairman, by the Duke of Northumberland as vice chairman, and by

and to tsetse-fly disease and surra in animals is very obvious, and the statement in the letter that this investigation is of imperial interest and that it will tend to benefit all our great tropical possessions is one which we can endorse while commending the appeal to public support.

WHAT IS BRANDY?

THE recent magisterial decision on this question—a decision which has our entire concurrence—is evidently having a wholesome effect upon the retail spirit trade. We learn that notices in very big type are being displayed in the bars of certain public-houses in the north of London announcing that "all spirit sold at this establishment as brandy is of the same superior quality as heretofore, but the percentage of pure grape spirit is not guaranteed." The value of analysis was discredited by the trade previously to the Islington prosecution case. It is an interesting sequel to the case that they now find that they must protect themselves against the further operations of analysis by disclosing to the purchaser the nature of the so-called brandy in such unmistakeable terms as are contained in the above notice.

"PUBLIC HEALTH" AT SPENNYMOOR.

THE urban district of Spennymoor in the county of Durham has achieved unenviable notoriety for its insanitary conditions and for the incompetence of its local governing bodies. Two years ago strong representations were made to the Registrar-General by the county council of Durham with the object of remedying the scandal of death registration in this district. During the seven years 1896 to 1902 uncertified deaths had formed, on an average, no less than 24 per cent. of the total deaths. Nearly all these deaths were uncertified as a result of unqualified medical practice and the action of the coroner and of the local registrars made it comparatively easy for such deaths to be registered without inquiry. It does not appear that this objectionable state of things has yet been remedied and meanwhile it has been shown that a large proportion of the uncertified deaths occur at early ages and that the death-rate from certain diseases of children would be materially increased if the facts about the cause of death had been in all cases properly ascertained. This is especially important, as even with the present faulty certification it is found that the mortality in Spennymoor from infantile diarrhœa and other diseases of children is exceptionally high. The general death-rate of the locality, and also the mortality from enteric fever, are also very unsatisfactory. A report by Dr. R. J. Reece, issued by the Local Government Board last year, showed that the district council of Spennymoor has been largely to blame for the unhealthiness of the place. Dr. Reece reported that all kinds of nuisances were allowed to arise through the want of paving, draining, and channelling of back yards and common yards and that soil pollution also occurred in consequence of the large open privy middens near the dwellings and the inefficient system of scavenging adopted. Sewers, where laid, had been constructed practically without plan and were imperfectly ventilated and defective in construction; the sewage was allowed to pollute the river Wear without treatment, even at outfalls where works of sewage disposal had been provided; by-laws were antiquated; and cowsheds, slaughter-houses, and especially common lodging-houses received no efficient supervision and in most cases were in an extremely insanitary state. The district council, though well advised by its medical officer of health, had neglected to attend to these and to many other defects, and Dr. Reece showed that where money has been spent in sanitary works it has not always been employed to the best advantage. It might have been expected that after this outspoken report the district council would have made an effort to obtain a better reputation for competency in the future but reports of its recent proceedings are far from encouraging. The most pressing need of the place is that there should be an active sanitary inspector with good knowledge of his duties. Yet when the office lately became vacant the district council passed over 122 candidates, of whom 82 held certificates of the Sanitary Institute or some similar body, and selected a coal-miner, lately a member of the council, who was without practical experience of sanitary work and possessed no certificate of competency. The Local Government Board has very properly refused sanction to the appointment. At its last meeting the district council declined to make a fresh appointment and resolved that the influence of two local Members of Parliament should be invoked in support of the coal-miner. The Members concerned will be wise to read Dr. Reece's report forthwith and to understand the unhealthy and dangerous conditions of life which this local "sanitary" authority is virtually asking them to encourage. It is to be hoped that the Local Government Board will continue to take a strong line with this obstructive district council and will bring it to a better understanding of its duties and responsibilities.

THE INFANT ORPHAN ASYLUM AT WANSTEAD.

IN THE LANCET of June 4th, p. 1610, we published a letter from Dr. W. P. Herringham and Mr. A. A. Bowlby concerning the decision of the committee of the Infant Orphan Asylum, Wanstead, not to provide an isolation block and also to abolish trained nurses. We have now before us the annual report of the medical officer of health of the Wanstead urban district council for the year 1903. In this report occurs the following passage concerning the Infant Orphan Asylum: "I am of opinion that the present infirmary accommodation is quite inadequate for the requirements of such an institution containing as it does nearly 600 inmates. My main point is this, that even apart from the ordinary beds where cases of ringworm can be treated, there is no separate block where infectious diseases can be isolated. The disinfector, which is now relied upon, is useless for the purpose." We can only repeat our contention that the friends of the institution will regret that the committee has adopted a course so incompatible with the expressed opinions of the medical staff and not only of the medical staff but of the medical officer of health of the district. Ringworm, it is well known, is a very infectious disease and the facts that the children are infants, are orphans, and are poor supply no reasons why they should be exposed to the risks of infection to which they must necessarily be exposed if proper accommodation for isolation and proper nursing are not provided.

THE VITAL STATISTICS OF BUENOS AYRES.

WHATEVER may be said for the cult of the beautiful in art, the achievements of architecture and engineering, the application of chemistry and electricity to the material prosperity and luxury of a community, or to the perfecting of the engines of destruction in modern war as indications and measures of progress in civilisation, it will scarcely be disputed that the successful working out of the principles of public health in a large and rapidly growing population is at least as good an indication as any of the former. Tried by this some of the most prosperous and "up-to-date" of our colonial cities would have to take a low place, while one, and we think one only, of those of South America would be found in the very front. Anyone interested in vital statistics will find the "Annuaire Statistique de la Ville de Buenos Ayres" most satisfactory reading, showing results highly creditable to the activities of the municipal authorities during the last 20 years. We have here a city with a most heterogeneous population rapidly growing both by immigration and by natural increase, with an extremely high birth-rate, especially among the predominant races of Italians, Spaniards, and "native" Argentines so-called, coupled with a very low general, and still lower infant and child, mortality. In 20 years the population has more than doubled itself and last year had reached a total of 895,000. The general death-rate which in the "eighties" had been as high as 27, has steadily fallen during the last decade from 19·0 to 15·6 per 1000. The birth-rate, after having averaged 40 for a number of years, has sunk to 35 3, but the infant mortality has gone down from 140 to no more than 80 per 1000 live births, while the child population, or number under five years of age, was 137,000, equal to 155 per 1000 of all ages, the proportion in England and Wales being 136. The death-rates from the two diseases or groups of diseases most fatal to infant life had fallen—that from diarrhœa, &c., from 56 to 19, and that from bronchitis, pneumonia, &c., from 38·57 to 15·94 per 1000 living under two years of age. Every disease in any way preventable by hygienic measures is steadily declining, though some are still higher than they might be, as tuberculosis (22·0) and typhoid fever (2·20), the figures for London being 17·3 and 1·44 per 10,000 inhabitants respectively, that from diphtheria, on the other hand, being 2·39, against 3·46 for London. Every people of Europe and America with some from Asia and Africa is represented among the immigrants and on an average half of these new-comers marry into other nationalities than their own, giving rise to a singularly mixed race. But the Italians and Spaniards come in overwhelming numbers—e.g., last year 42,358 Italians and 21,917 Spaniards, equal to 64,275 out of a total of 75,227 immigrants, so that the Argentine proper may be looked on as essentially a blend of these two and the fertility of the two pure and mixed races is remarkable, families of from 15 to 20 being of not infrequent occurrence. Montevideo, on the opposite shore of the mouth of the Rio de la Plata, holds a position among South American towns second to Buenos Ayres only, but Santiago de Chili in the same latitude and enjoying one of the most perfect climates in the world is at the same time one of the unhealthiest cities in every way.

THE TAMWORTH TOWN COUNCIL AND THE REPORT OF ITS MEDICAL OFFICER OF HEALTH.

ACCORDING to the *Tamworth Mercury* of June 11th the mayor of that borough has recently had reason to deplore "a repetition of those extremely unpleasant scenes in the past which made that council improperly, if he might say so, but at any rate undesirably, famous throughout the country." The occasion for the outbursts referred to appears to have been "the action of the medical officer of health in sending his annual report to the Local Government Board and the county council without first intimating to this council his intention to do so," an omission which, in the opinion of the sanitary and streets Committee, was "discourteous to the committee." We have not yet received a copy of the report in question and so far as we can judge, seeing that the committee is apparently disinclined to print it, we are not likely to do so. But as the merits of the report do not really arise this point is immaterial and, moreover, the account in the *Tamworth Mercury* throws some interesting sidelights upon the unwillingness of the committee to have the report printed. It is curious that a local administering body which has risen to the dignity of a town council should not have been accurately informed as to what is the precise position of the medical officer of health with respect to his annual report and what are his instructions relative thereto. Doubtless the town council could have ascertained all the facts from its town clerk, but it would seem that the mayor, who "will always try to prevent the town from being governed by officials as it had been," was too proud to seek advice from the proper quarter. In these circumstances it may be well that we should draw attention to Article 16 of the Order of the Local Government Board which was issued on March 23rd, 1891. This Order provides that when giving information to the Local Government Board of the outbreak of infectious disease or transmitting to it a copy of his annual report or of any special report he must give the like information or transmit a copy of such report to the county council or county councils of the county or counties within which his district may be situated. Obviously, therefore, Dr. H. J. Fausset, the medical officer of health, had no alternative but to submit at once a copy of his report to the Local Government Board. Had that Board wished for the reports of medical officers of health as "revised" by the local authorities it would doubtless have asked for this in its Order and in that case it would never have learnt that "the work of inspection of the borough with regard to the removal of nuisances required more attention." Possibly this may be one of the paragraphs which it was the object of a defeated amendment to omit but whether or not this is the case the country will now know that things are not as they should be at Tamworth. We gather, too, from Mr. Dewes, one of the councillors who supported the medical officer of health, that there is much truth in the report and that it should not be tampered with because such reports "ought to be ungarbled and unaltered but express straightforwardly" the views of the medical officer of health on the sanitary condition of the borough. As Mr. Dewes pertinently observed, the council could not absolve the medical officer of health "from his duty to send his report to the Local Government Board." The medical officer of health is, Mr. Dewes added, the "eye" of the Local Government Board, which body looked to him for an independent report. Alderman Hare agreed with Mr. Dewes and in his view the action of the committee suggested the idea that there was something in the report which was incorrect. He considered it "an excellent report with nothing at all wrong about it." Having now obtained the report both the Local Government Board and the county council may be anxious for the observations of the Tamworth town council upon some of its passages. Possibly it may select those two passages which were the subject of the amendment. The town council has clearly made a mistake and it would do well at its next meeting to acknowledge frankly the fact to Dr. Fausset.

POISONING BY ILLUMINATING GAS.

ATTENTION to the important matter of poisoning by illuminating gas, of which 290 fatal cases occurred in New York city alone in 1901, is drawn by Dr. W. G. Thompson in a paper read at the recent annual meeting of the Association of American Physicians held at Washington in May and published in *American Medicine* of May 28th. Dr. Thompson's investigations were undertaken to determine the cause of death and of certain symptoms that are characteristic of poisoning by illuminating gas. A brief account of some of these symptoms was published, with illustrative cases, in THE LANCET of Oct. 11th, 1902. The series of cases studied by Dr. Thompson include 90, of which 17 were fatal. It is estimated that in New York probably 2000 cases of poisoning by gas occur annually. This is due to the prevalent use of the gas stove and to the ignorance of the foreign population going into the city. The deleterious effect of the gas on the blood, when inhaled, is due to one of its constituents, carbon monoxide, which firmly combines with the hæmoglobin of the red corpuscles and thus deprives the blood of its normal oxygen-absorbing power. But, adds Dr. Thompson, the action of the carbon monoxide upon the nervous system is more important than the changes produced in the blood. A leucocytosis which lasts for many days is one of the changes produced, while a febrile reaction is also developed in the system. The character of the fever is varied; a subnormal temperature may exist for some hours and then be followed by a fever which persists and remains high for a week or more. One case of pyrexia was observed in which the temperature reached 110° F. The associated nervous symptoms are varied in character. They consist of headache and mental confusion or delirium passing into coma in severe cases, muscular tremors and twitchings, anæsthesia of the skin, and rigidity of the muscles combined with opisthotonos. Among the later sequelæ there occur sclerosis and destructive changes in the brain and bulbo-spinal cord or in the peripheral nerves. The most satisfactory form of treatment was found to be venesection to the extent of about two pints of blood with simultaneous infusion of an equal quantity of warm and sterile physiological saline solution. In the discussion which followed the communication of Dr. Thompson's paper at the meeting referred to Professor Stengel of Philadelphia drew attention to recent experimental work which had shown that the transfusion of defibrinated blood had saved animals (rabbits, dogs) poisoned by coal gas even when venesection and infusion with salt solution failed. Professor S. Weir Mitchell and Professor Solis Cohen directed attention to the varying composition of illuminating gas in different cities; it was more highly charged with carbon monoxide, acetylene, and other highly toxic constituents at certain times than at others. Much leakage of gas took place into the cellars and basements in streets where the main gas-supply pipes had been badly laid and the slow and chronic poisoning of persons exposed to the influence of leaking gases was established by investigation in various large cities. Dr. Peabody said that defibrinated blood was difficult to procure as it had to be fresh and he supported the conclusions of Dr. Thompson that prompt treatment of all severe cases with venesection and saline transfusion had saved the lives of many persons poisoned by gas.

THE PROVISION OF OUTDOOR MEDICAL RELIEF.

IN attempting to improve the conditions under which the wants of the sick poor of their district are ministered to the Lambeth guardians have taken a step which may have far-reaching consequences, especially as regards the status of Poor-law medical officers. At a recent meeting of the board a special committee which had been appointed to consider the question of outdoor medical relief reported favourably upon a scheme which has been for some time under discussion and which proposes to substitute for the present district medical officers a staff of medical men who should devote their whole time to relief work and be under the direct control of the chief medical officer of the workhouse infirmary. In the opinion of the committee this plan promises so well that it advises its adoption in certain of the districts of the parish and it proposes that four medical officers at salaries ranging from £100 to £250 per annum should be appointed in order to give to the suggested arrangement a fair trial. There is, of course, no imputation that the existing district medical officers fail to carry out their duties as efficiently as possible and we assume that when the new arrangement comes into effect the interests of these gentlemen will be adequately safeguarded. Provided that this is done the proposed change is one likely to be to the advantage of both the sick poor and their medical attendants. The former will cease to run any risk of having their claims upon the time of a district medical officer subordinated to those of private patients, while the latter will have an opportunity of setting on foot a scheme of organisation which may do something to lift the Poor-law service from its present unsatisfactory position. There seems, indeed, to lie in the Lambeth proposal the germ of great possibilities. We may eventually get in this particular branch of our national undertakings a Poor-law Medical Corps in relation with the Local Government Board and comparable with the Royal Army Medical Corps. Such a development could hardly fail to increase greatly the prestige and the efficiency of the medical men engaged in Poor-law work. Until the experiment has been tried it is difficult to form an even approximately accurate estimate of its cost but at the salaries which the Lambeth board offers there does not seem likely to be any serious addition to the present expenditure. There is, moreover, a further prospective advantage in that the nursing of the sick poor could be intrusted to women trained under the medical superintendent of the infirmary and recognising in him and the medical officers under him a legitimate authority whose instructions they would readily obey.

EMPYEMA OF THE FRONTAL SINUS FOLLOWED BY CEREBRAL ABSCESS.

ABSCESS of the brain is a rare result of empyema of the frontal sinus. In the *American Journal of the Medical Sciences* for April Dr. Paul S. Mertins has reported the following case. A man, aged about 40 years, sought medical advice on Sept. 8th, 1903. For six months he had suffered from violent headaches of increasing severity. Within the last three days a swelling of the size of a goose's egg appeared in the re[illegible]. It was fluctuating and very tender. [illegible] apparently thickened periosteum, was fe[illegible]. 16 years before he contracted syphilis and two years before he received a blow with a hammer on the top of the head and was unconscious for several days. The swelling was incised and about an ounce of dark-coloured pus was evacuated, with complete relief of the pain. On the third day the pain returned and the patient noticed that when he held his head forward the flow of pus increased and the pain diminished. On the night of Sept. 13th the pain became more severe and the patient vomited several times and had three convulsions. On the following morning he was seen in consultation by Dr. Mertins. Cerebration was slow but no paralysis could be found. The anterior end of the middle turbinate bone was swollen. The temperature was 97·5° F. On probing the wound necrosed bone was found and in several places the probe seemed to enter the cranial cavity. Extradural abscess was diagnosed and the patient was admitted to hospital for operation. Under chloroform a three inch incision was made through the seat of the abscess. The pericranium was found separated from the bone and was held back by retractors. An area of necrosed bone of the size of a dollar was exposed. It was of a dark brown colour and presented the appear[illegible] in consequence of the numerous [illegible] pus oozed at each respiration. A button of bone was removed from the centre of the necrosed area with a half-inch trephine. An extradural abscess containing about an ounce of pus was found. The trephine opening was enlarged to the size of a dollar. The dura mater was found adherent to the frontal bone all around and formed the bed of the abscess. The removal of the necrosed bone opened the left frontal sinus which contained about half an ounce of pus. The right frontal sinus was opened and found to be healthy. The dura mater was of a dirty yellowish colour and pulsated only on the left side. On the 15th the patient's general condition was good and his mind was clearer but still not normal. There was a condition of irritability with semi-stupor and the urine was passed involuntarily. On the 23rd there were transient paresis of the right internal rectus muscle and right optic neuritis On the 24th he was more stupid. An aspirating needle introduced into the right frontal lobe was felt to enter a cavity and pus flowed through it A pair of scissors was entered beside it and the blades were separated. About one and a half ounces of creamy pus and a yellowish lump of broken down brain tissue were evacuated The cavity was curetted and an iodoform gauze drain was introduced The mental condition at once improved and the pulse rose from 78 to 100 On the following days the patient's condition continued to improve slowly and the abscess cavity grew smaller and the discharge less, but on the 30th there were symptoms of hypostatic congestion of the inferior lobe of the right lung and hæmoptysis The wound was in good condition On Oct 3rd the left lung became involved He grew worse and died on the 5th At the necropsy a depressed fracture of the size of a hammer head was found in the left parietal bone half an inch deep near the sagittal suture The bone was healthy This fracture was probably the result of the blow received two years previously Around the trephine opening the dura mater was adherent to both the bone and the brain It was also adherent to the depressed fracture The brain showed an abscess cavity one and a half inches deep, surrounded by nearly normal tissue The inferior lobes of the lungs were in a state of hypostatic congestion Dr Mertins thinks that but for the pulmonary complication the patient would have recovered from the cerebral abscess The abscess was the result of the empyema of the frontal sinus The posterior wall of the latter was necrosed and a fistulous tract led from the sinus to the extradural abscess

A MUSICAL [illegible] THE [illegible]

ON May 29th at the Grafton Galleries, under the auspices of the Sunday Concert Society, Madame Magdaleine, an artist who claims to interpret the emotions of music by dancing and artistic movements executed while in a state of induced "hypnotism," made her *debut* in London While in a "hypnotic" state on this occasion music was played and Madame Magdaleine illustrated the various moods reflected in the music by appropriate poses and dances The musical instruments were a violin, a piano, a Mustel organ, and a celesta A brief account of the séance was published in THE LANCET of June 4th, p. 1621 As doubt was expressed in some quarters as to the reality of the apparent hypnosis a matinée performance was given at the Garrick Theatre on June 9th, when, supported by music and scenery, Madame Magdaleine appeared on the stage and again went through her performance She was introduced by a M Magnin of Paris who seated her on a chair and, holding her two hands, gazed into her face for some seconds He then made a few "passes" over her face until she passed into the supposed hypnotic condition and then led her to the centre of the stage Music was then played and the artist began to dance. Her attitude was still and somewhat rigid until the first notes on the Mustel organ were struck. It then underwent a change. Consciousness seemed to light up, as it were, the face became expressive, and she danced and moved with grace and skill, interpreting the significance and the emotions of the music into movement with great facility This was followed after a brief pause by a song, "Les Rameaux," sung by Mr —— and accompanied on the Mustel organ. The artist danced and moved to this well known song with exceeding animation and grace, all the appropriate emotions, and attitudes of prayer and praise, devotion, joy, sorrow, and reverence being expressed with the highest art. Other items, four in number, followed, which concluded the first part of the programme During the interval, at the invitation of M Magnin, Madame Magdaleine was seen and briefly examined on the stage by a representative of THE LANCET She was found to be in a condition of cataleptic rigidity of the arms and legs, the pupils were moderately contracted, and the eyeballs were converged and turned slightly downwards The pupils reacted sluggishly to light Her skin was covered with sweat from the exertions of the dance, but the pulse, though full and strong, was not accelerated, its beat averaging from 75 to 80 per minute The knee jerks were tested after relaxation of the legs was induced (by passes made by M Magnin) and found to be absent, but as a slight degree of rigidity persisted in the legs this test could not be regarded as conclusive The test for anæsthesia of the skin with a pin was not allowed Madame Magdaleine's whole condition was suggestive of the hypnotic or somnambulistic stage, a condition of subconsciousness without any apparent spontaneity She was now restored to consciousness by the passes of M Magnin During the second half of the programme the representative of THE LANCET stood at the wing of the stage and watched her closely, following every movement, action, and pose from an excellent position of observation The dancer's eyes never for a moment dwelt, or seemed to dwell, upon the pianist or on any of the other instrumentalists on the stage, or upon any person at the wings of the stage, but were moved as though she were the subject of visual hallucinations during her dancing Whether this was acting and feigned or whether real hallucinations were seen could not be decided in the time and by the means afforded. The performance was throughout characterised by grace and beauty of movement in dancing Whatever may be said, Madame Magdaleine is a thorough artist and her dancing, gracefulness of movement, and wonderful power of facial and pantomimic expression constitute a performance worth seeing The tests applied and the observations made by the representative of THE LANCET incline him to the belief that the hypnosis is genuine and not feigned, and that the performances are carried out during the hypnotic state But a further study of this interesting case would be needed before all doubt could be settled as to the genuineness of the phenomena M Magnin states that Madame Magdaleine is a Russian born woman of mixed French and Swiss parentage and that the family history of both her parents is free from serious neuroses or brain affections She is married to a Frenchman and is the mother of two children He also states that when not under the influence of hypnotism she is in no sense an artist nor has she any skill as a musician or interpreter of music into movement. The psychological aspects of this case are certainly of interest.

THE EAST LONDON MEDICAL SOCIETY AND HOSPITAL ABUSE

THE East London Medical Society at a meeting held on May 17th decided to memorialise various hospitals on the subject of the abuse of hospital charity Deputations from the society have met the house committees of two of the East London hospitals The matter was discussed and it was promised that steps would be taken to diminish as far as possible certain abuses the existence of which was admitted. The abuses that the society complained of more particularly were (1) the part payment system at hospitals, and (2) the insufficiency of the scrutiny of patients to prevent treatment at hospitals of persons whose means render them unsuitable for relief at a charitable institution The society also pointed out that the hospital authorities are almoners of the charitable public, that it is their bounden duty to see that the money intrusted to them is applied in relieving deserving cases; that to expend it otherwise is to commit a grave breach of trust; and that to expend it on those whose means render them unfit for such relief is a course calculated to pauperise the recipients and to sap their independence of character. The society contends that a proportion of the funds subscribed by the charitable public is wasted on unsuitable subjects and it intends to press for reform at all institutions where these abuses exist. In order to give greater weight to its representations the society would strongly urge medical practitioners to join it, as it is fighting for reforms which intimately affect the whole profession and the charitably disposed public.

AN OUTBREAK OF CASES OF SORE-THROAT APPARENTLY CONNECTED WITH AN INFECTIVE ERUPTION ON THE TEATS OF COWS.

WE have received a report of considerable interest on a recent outbreak of infective sore-throat in the Fever and Small-pox Hospitals at Belvidere, Glasgow, in which a considerable amount of evidence is adduced connecting it with an infective eruption on the teats of the cows from which the milk-supply was derived. The facts may be briefly summarised as follows. During the months of April and May 39 persons more or less directly connected with the institutions suffered from certain throat symptoms, variously regarded as tonsillitis and diphtheria, while 13 of the cases were so slight in character that no medical advice was sought. Bacteriologically a few of the cases showed diphtheria bacilli, a few others pseudo-diphtheria bacilli, and the remainder of those examined only streptococci. On considering the occupations of the various persons affected it became obvious that the disease was spread by a direct distribution from a common source rather than by secondary transmission among persons closely associated in their work and habitation. As certain cases occurred in the small-pox hospital and in the house steward's family attention was directed to the milk-supply, this being the only apparent circumstance in common between them and the fever hospital generally. After May 17th the milk supplied to the fever hospital was scalded and no further cases occurred there, but by a mistake in the instructions sent to the small-pox hospital the milk supplied there was not scalded till May 23rd and one case occurred there on the 27th. On investigating the source of the milk it was discovered that on April 23rd a new cow had been added to the herd which then numbered 72 in all. This cow had a slight eruption on the teats at the time but as this gave rise to no difficulty in milking little or no notice was taken of it. The cow was placed in one of the byres with a certain group of cows and within a few days it was moved to another byre and placed with another group. Subsequently the animals in both these groups were found to be suffering from a similar eruption on the teats and as a result 30 per cent. of the whole herd were affected. The disease appears to have lasted about three days, during which the animals gave some extra trouble in milking; after this, although the lesions persisted for a while, the cows took no notice of them and milking was not more difficult than usual. During the course of the epidemic the hands of four out of the eight milkers employed were affected with an eruption which subsequently healed and was apparently due to infection from the teats. As far as circumstantial evidence can go the connexion between the two conditions would appear to be a very close one. The direct or bacteriological proof is still engaging the attention of the medical officers. As far as this part of the investigation has gone, in one of the cases, that of a medical officer in charge of diphtheria wards, the *organisms were those of true diphtheria, although it is, of* course, possible that the original determining cause of the more virulent infection may have been the same infective agent as in the other cases acting by lowering resistance and thus favouring the diphtheritic infection. Dr. A. K. Chalmers, the medical officer of health and author of the report, is disposed to regard the throat-sympton as due to a septic infection arising from the growth secondary organisms on the affected teats and conveyed the milk. The complete bacteriological report of the prese outbreak should be of great interest.

A VISIT OF FRENCH MEDICAL MEN TO LONDON.

Sir William S. Church, Bart., K.C.B., President of t Royal College of Physicians of London, will take the cha at a meeting to be held at the College, Pall Mall East, S.W on Thursday, June 23rd, at 5 P.M., to consider the arrang ments which should be made to receive the party of Frenc physicians and surgeons who propose to visit London Oct. 10th, 11th, and 12th. The appointment will proposed of an executive committee containing represent *tives of the principal hospitals and laboratories in Londo* which the French visitors may wish to see. The followin committees have been organised in Paris:—*Comité Patronage:* *M. Bouchard, professeur de patholog générale; M. Brissaud, professeur de pathologie interne M. Brouardel, professeur de médecine légale; M Chantemesse, professeur à la Faculté; *M. Chauffar professeur agrégé, médecin de l'Hôpital Cochin; M Dieulafoy, professeur de Clinique Médicale; M. Joffro professeur de médecine mentale; *M. Landouzy, professe de thérapeutique; *M. Marie, professeur agrégé, médecin l'Hospice de Bicêtre; *M. Lucas Championniere, professeu agrégé, chirurgien de l'Hôtel Dieu; M. Poirier, professe d'Anatomie; M. Terrier, professeur de clinique chirurgicale *M. Lermoyez, laryngologiste de l'Hôpital Saint Antoine; an *M. Sebileau, professeur agrégé, laryngologiste de l'Hôpit Lariboisiere. (Those marked * have expressed the intention of accompanying the party to London.) *Com d'Organisation:* Dr. Triboulet, médecin des Hôpitau Président du Comité; Dr. Apert, médecin des Hôpitaux Dr. Bezançon, professeur agrégé; Dr. Claude, professe agrégé; Dr. Comby, médecin des Hôpitaux; Dr. Cuné professeur agrégé; Dr. Launay, chirurgien des Hôpitaux Dr. Lombard, médecin des Hôpitaux; and M. Paul Lutau interne en exercice.

ARRANGEMENTS have been made by the Council the Royal Institute of Public Health for a dinner o June 30th at 7 P.M. at the Criterion, Piccadilly, to th Right Hon. Joseph Chamberlain, M.P., in recognition of hi services whilst Colonial Secretary to preventive and tropica medicine. The council will be glad to welcome anyon interested in these subjects. Tickets for the dinner can b obtained at 19, Bloomsbury-square, W.C. It is speciall mentioned that the dinner has no political connexion.

THE King has given and granted to Dr. Donald Harve Attfield, director and principal medical officer of the Sue Quarantine Office, the Royal licence and authority to accep and to wear the Imperial Ottoman Order of the Osmanieh Fourth Class, which has been conferred upon him by hi Highness the Khedive of Egypt, authorised by his Imperia Majesty the Sultan of Turkey, "in recognition of valuabl services rendered to his Highness."

THE Queen has consented to visit the People's Palace, Mile end, in order to open the annual summer flower show of the People's Palace and East London Horticultural Society, o which the Duke of Fife is President, on the afternoon o July 14th. The proceeds of this show are to be devoted to the funds of the London Hospital, of which Her Majesty is the President.

AT the annual prize giving of the London (Royal Free Hospital) School of Medicine for Women, which will take place on Thursday, June 23rd, at 4 P.M., Professor T. Clifford Allbutt, F.R.S., Regius Professor of Physic at Cambridge, will present the prizes.

THE Right Hon. Lord Alverstone, G.C.M.G., Lord Chief Justice of England, will distribute the prizes to the students of St. Mary's Hospital Medical School, London, at the annual distribution on Wednesday, June 29th, at 4.45 P.M.

WE regret to announce the death of Mr. A. O. Mackellar, surgeon-in-chief to the Metropolitan Police and late senior surgeon to St. Thomas's Hospital.

THE INTERNATIONAL HOME RELIEF CONGRESS.

THE fourth of these congresses took place last week in Edinburgh and was attended by more than 400 members, more than half of whom were ladies, whilst several had come from France, Belgium, Holland, and other foreign countries. The first of these congresses was held in Paris in 1901, the second in Antwerp, and the third in Bordeaux. The idea of holding them arose at a Paris congress in 1900 which dealt with charitable work of every kind, the work of hospitals and other institutions being included. But the discussions which took place showed clearly that the questions relating to Home Relief presented special problems embracing so wide a field and of such urgent importance that it was resolved that in the future an independent congress should be devoted to their consideration.

Lord BALFOUR OF BURLEIGH, the President, in his opening address defined the general object of the conference as the discussion of those methods by which help could best be given to our weaker and less fortunate brethren without relegating them to special institutions where recipients of relief are congregated together. In many ways this system commends itself to Scotland, for last month the percentage of ordinary poor in the various poor-houses was only 13, compared with 87 per cent. receiving outdoor relief.

The congress was divided into five sections, most of which discussed matters of medical interest.

I.—CHILDREN.

Miss HORN (school manager under the London School Board) read a paper on the Feeding of Infants and School Children, with the object of showing that the feeding of children from the school as a centre was a bad method of relief.—Dr. H. W. THOMSON (Glasgow) dealt with the Eye Troubles of Children, especially Myopia and Strumous Ophthalmia, and pointed out that employers often refused to engage a man who was obliged to wear spectacles.—Dr. F. M. SANDWITH (London) described the objects of the Infants' Health Society and drew attention to the high infantile mortality of the United Kingdom.—Dr. W. ROBERTSON (Edinburgh) stated that pasteurised cow's milk ready mixed with water, sugar, and salt was now provided for 74 infants daily in separate bottles, for which the mothers paid 1*s.* 6*d.* a week and yet the milk depôt was self-supporting. During 15 months none of these children had died from diarrhœa.

In a crowded meeting to discuss the home care of mentally defective children the opinion was expressed that these could be trained and kept for life with most advantage to themselves and others in labour schools and colonies in the country where the workers might actually produce the food on which they lived.

II.—ABLE-BODIED ADULTS.

Mr. J. Q. DONALD (Fife), in a paper on What to Do with our Inebriates, stated that the only method in which he believed was the confinement of the patient in a retreat where it was necessary to implant in the patient's mind a loathing for his old habits. He quoted several cases which he had successfully treated.—Dr. J. F. SUTHERLAND (Edinburgh), on the other hand, thought that inebriates should be housed out in the country, but not more than two in any one house.—Dr. R. W. BRANTHWAITE (London) said that out of the last 1000 committals from England he did not know one case that could have been sent from the court to a private house over which any ordinary individual would have control.

III.—SICK ADULTS.

This section was presided over by Mr. MALCOLM A. MORRIS and began with a discussion on the Means of Home Attendance [illegible] er papers by Dr [illegible] (Amsterdam), [illegible] s. SCHARLIEB, M.D. (London). On the second day Dr. R. W. PHILIP (Edinburgh), while recognising the value of sanatoriums, pleaded *for a properly equipped tuberculosis dispensary* under the direction of the local authority as being the best means to organise the campaign against phthisis and a motion to this effect was unanimously carried. He calculated that there were *now* in Edinburgh 2500 *persons* who would die from tubercle during the next five years. At the Victoria Dispensary for Consumption 87 patients had attended on one day and there were up to the present time 13,360 patients on the books who had been visited at their homes by a willing staff of nurses and ladies. The meeting loudly applauded the view that the tuberculosis dispensary should be placed under the medical officer of health and under the local authority. Besides the tuberculosis dispensary Dr. Philip recommended a home for dying patients, chiefly in the interests of other persons; sanatoriums for selected patients who required a special régime not procurable in their own homes; and colonies for the after-life and supervision of patients in whom the disease had been sufficiently arrested to make selected open-air employment feasible and desirable.—A paper was read from Professor CALMETTE (Lille) describing his tuberculosis dispensary started three years ago for superintending ex-patients. 100 families received daily rations of coals, meat, milk, and eggs, while their linen was washed for them and their houses were disinfected periodically.—Professor J. A. LINDSAY (Belfast) reported two reforms from his municipality—the appointment of two female inspectors for visiting ex-patients and the gratuitous examination for tubercle of sputa.

After a debate on the third day on the relation between hospital and home relief of sick poor the following motion was carried:—

[illegible] experience may suggest.

IV.—INSANE AND EPILEPTICS.

Dr. A. ROBERTSON (Glasgow) opened a discussion on the Scottish system of boarding out the insane poor in private dwellings.—Mr. CONOLLY NORMAN (Dublin) said in his remarks that there was in Ireland one person of unsound mind to every 178 of the general population.—Sir JOHN SIBBALD (Edinburgh), in speaking of the Bill just introduced in the House of Commons by the Attorney-General to permit cases of doubtful or incipient insanity being sent to private homes for a period not exceeding six months without the formality of certificates, said he greatly objected to applying to the insane a word which could be made to refer to them alone. He welcomed the substitution of "hospitals" for "asylums" and said in Edinburgh they had now gone one step further, for there was a new asylum being constructed which is to be called "The Bangour Village."

An important discussion on epileptic colonies took place. Dr. J. M. RHODES (Manchester) stated that there were certainly not less than 70,000 epileptics in Great Britain and for the treatment of that number there was not one single State institution for the proper scientific care of the sane epileptic.—Dr. FLETCHER BEACH (London) mentioned that the number of colonists was now 196 at the Chalfont Farm in Buckinghamshire.—Dr. D. FRASER (Paisley) contributed a paper with special reference to the colony at Bethal in bounden duty to see that the money intrusted to them is applied in relieving deserving cases; that to expend it otherwise is to commit a grave breach of trust; and that to expend it on those whose means render them unfit for such relief is a course calculated to pauperise the recipients and to sap their independence of character. The society contends that a proportion of the funds subscribed by the charitable public is wasted on unsuitable subjects and it intends to press for reform at all institutions where these abuses exist. In order to give greater weight to its representations the society would strongly urge medical practitioners to join it, as it is fighting for reforms which intimately affect the whole profession and the charitably disposed public.

AN OUTBREAK OF CASES OF SORE-THROAT APPARENTLY CONNECTED WITH AN INFECTIVE ERUPTION ON THE TEATS OF COWS.

WE have received a report of considerable interest on a recent outbreak of infective sore-throat in the Fever and Small-pox Hospitals at Belvidere, Glasgow, in which a considerable amount of evidence is adduced connecting it with an infective eruption on the teats of the cows from which the milk-supply was derived. The facts may be briefly summarised as follows. During the months of April and May 39 persons more or less directly connected with the institutions suffered from certain throat symptoms, variously regarded as tonsillitis and diphtheria, while 13 of the cases were so slight in character that no medical advice was sought. Bacteriologically a few of the cases showed diphtheria bacilli, a few others pseudo-diphtheria bacilli, and the remainder of those examined only streptococci. On considering the occupations of the various persons affected it became obvious that the disease was spread by a direct distribution from a common source rather than by secondary transmission among persons closely associated in their work and habitation. As certain cases occurred in the small-pox hospital and in the house steward's family attention was directed to the milk-supply, this being the only apparent circumstance in common between them and the fever hospital generally. After May 17th the milk supplied to the fever hospital was scalded and no further cases occurred there, but by a mistake in the instructions sent to the small-pox hospital the milk supplied there was not scalded till May 23rd and one case occurred there on the 27th. On investigating the source of the milk it was discovered that on April 23rd a new cow had been added to the herd which then numbered 72 in all. This cow had a slight eruption on the teats at the time but as this gave rise to no difficulty in milking little or no notice was taken of it. The cow was placed in one of the byres with a certain group of cows and within a few days it was moved to another byre and placed with another group. Subsequently the animals in both these groups were found to be suffering from a similar eruption on the teats and as a result 30 per cent. of the whole herd were affected. The disease appears to have lasted about three days, during which the animals gave some extra trouble in milking; after this, although the lesions persisted for a while, the cows took no notice of them and milking was not more difficult than usual. During the course of the epidemic the hands of four out of the eight milkers employed were affected with an eruption which subsequently healed and was apparently due to infection from the teats. As far as circumstantial evidence can go the connexion between the two conditions would appear to be a very close one. The direct or bacteriological proof is still engaging the attention of the medical officers. As far as this part of the investigation has gone, in one of the cases, that of a medical officer in charge of diphtheria wards, the organisms were those of true diphtheria, although it is, of course, possible that the original determining cause of the more virulent infection may have been the same infective agent as in the other cases acting by lowering resistance and thus favouring the diphtheritic infection. Dr. A. K. Chalmers, the medical officer of health and author of the report, is disposed to regard the throat symptoms as due to a septic infection arising from the growth of secondary organisms on the affected teats and conveyed in the milk. The complete bacteriological report of the present outbreak should be of great interest.

A VISIT OF FRENCH MEDICAL MEN TO LONDON.

Sir William S. Church, Bart., K.C.B., President of the Royal College of Physicians of London, will take the chair at a meeting to be held at the College, Pall Mall East, S.W., on Thursday, June 23rd, at 5 P.M., to consider the arrangements which should be made to receive the party of French physicians and surgeons who propose to visit London on Oct. 10th, 11th, and 12th. The appointment will be proposed of an executive committee containing representatives of the principal hospitals and laboratories in London which the French visitors may wish to see. The following committees have been organised in Paris:—*Comité de Patronage:* *M. Bouchard, professeur de pathologie générale; M. Brissaud, professeur de pathologie interne; M. Brouardel, professeur de médecine légale; M. Chantemesse, professeur à la Faculté; *M. Chauffard, professeur agrégé, médecin de l'Hôpital Cochin; M. Dieulafoy, professeur de Clinique Médicale; M. Joffroy, professeur de médecine mentale; *M. Landouzy, professeur de thérapeutique; *M. Marie, professeur agrégé, médecin de l'Hospice de Bicêtre; *M. Lucas Championniere, professeur, agrégé, chirurgien de l'Hôtel Dieu; M. Poirier, professeur d'Anatomie; M. Terrier, professeur de clinique chirurgicale; *M. Lermoyez, laryngologiste de l'Hôpital Saint Antoine; and *M. Sebileau, professeur agrégé, laryngologiste de l'Hôpital Lariboisiere. (Those marked * have expressed their intention of accompanying the party to London.) *Comité d'Organisation:* Dr. Triboulet, médecin des Hôpitaux, Président du Comité; Dr. Apert, médecin des Hôpitaux; Dr. Bezançon, professeur agrégé; Dr. Claude, professeur agrégé; Dr. Comby, médecin des Hôpitaux; Dr. Cunéo, professeur agrégé; Dr. Launay, chirurgien des Hôpitaux; Dr. Lombard, médecin des Hôpitaux; and M. Paul Lutaud, interne en exercice.

ARRANGEMENTS have been made by the Council of the Royal Institute of Public Health for a dinner on June 30th at 7 P.M. at the Criterion, Piccadilly, to the Right Hon. Joseph Chamberlain, M.P., in recognition of his services whilst Colonial Secretary to preventive and tropical medicine. The council will be glad to welcome anyone interested in these subjects. Tickets for the dinner can be obtained at 19, Bloomsbury-square, W.C. It is specially mentioned that the dinner has no political connexion.

THE King has given and granted to Dr. Donald Harvey Attfield, director and principal medical officer of the Suez Quarantine Office, the Royal licence and authority to accept and to wear the Imperial Ottoman Order of the Osmanieh, Fourth Class, which has been conferred upon him by his Highness the Khedive of Egypt, authorised by his Imperial Majesty the Sultan of Turkey, "in recognition of valuable services rendered to his Highness."

THE Queen has consented to visit the People's Palace, Mile-end, in order to open the annual summer flower show of the People's Palace and East London Horticultural Society, of which the Duke of Fife is President, on the afternoon of July 14th. The proceeds of this show are to be devoted to

ANALYSIS OF SICKNESS AND MORTALITY STATISTICS IN LONDON DURING MAY, 1904.

(*Specially compiled for* THE LANCET.)

CITIES AND BOROUGHS	Estimated population in the middle of 1904.	NOTIFIED CASES OF INFECTIOUS DISEASE.											DEATHS FROM PRINCIPAL INFECTIOUS DISEASES.											Deaths from all causes.	Death-rate per 1000 living.	Deaths of infants under one year to 1000 births.
		Small pox.	Scarlet fever.	Diphtheria.*	Typhus fever.	Enteric fever.	Other continued fevers.	Puerperal fever.	Erysipelas.	Cholera.	Total.	Annual rate per 1000 persons living.	Small pox.	Measles. * Including membranous croup.

the average number in the corresponding periods of the ten preceding years; among the various metropolitan boroughs this disease was proportionally most fatal in Holborn, Stepney, Poplar, Southwark, Bermondsey, and Deptford. The fatal cases of scarlet fever numbered 19 last month, against an average of 48 in the corresponding periods of the ten preceding years; this disease showed the highest proportional fatality in St. Pancras, Hackney, Finsbury, Bethnal Green, Poplar, and Southwark. The 63 deaths from diphtheria were equal to exactly one-half of the corrected average number; among the various metropolitan boroughs this disease was proportionally most fatal in Stoke Newington, Hackney, Shoreditch, Poplar, Wandsworth, and Woolwich. The 163 fatal cases of whooping-cough showed a decline of 39 from the average number in the corresponding periods of the ten preceding years; the greatest proportional mortality from this disease occurred in Finsbury, Shoreditch, Lambeth, Camberwell, Deptford, and Woolwich. The deaths from "fever" numbered 12 last month, the corrected decennial average being 27; the highest "fever" death-rates occurred in Fulham, Islington, Stoke Newington, Holborn, Stepney, Bermondsey, and Woolwich. The 74 fatal cases of diarrhœa were 21 in excess of the corrected average number; among the various metropolitan boroughs this disease was proportionally most fatal in Fulham, the City of Westminster, Shoreditch, Southwark, Battersea, Wandsworth, and Woolwich. In conclusion, it may be stated that the aggregate mortality in London last month from the principal infectious diseases was more than 15 per cent. below the average.

Infant mortality, measured by the proportion of deaths among children under one year of age to registered births, was equal to 107 per 1000. The lowest rates of infant mortality were recorded in Paddington, Chelsea, St. Marylebone, Hampstead, Stoke Newington, Hackney, and Camberwell; and the highest rates in Finsbury, Bethnal Green, Stepney, Poplar, Southwark, Bermondsey, and Battersea.

THE SERVICES.

Royal Navy Medical Service.

THE following appointments are notified:—Surgeons: P. T. Nicholls to the *Mutine* and J. H. Jones to the *Lizard*.

In accordance with the provisions of Her late Majesty's Order in Council of April 1st, 1881, Fleet Surgeon William Spencer Lightfoot has been placed on the Retired List at his own request, with permission to assume the rank of Retired Deputy Inspector-General of Hospitals and Fleets (dated June 9th, 1904).

Army Medical Reserve of Officers.

Surgeon-Lieutenant G. R. Livingston to be Surgeon-Captain (dated June 5th, 1904).

Volunteer Corps.

Rifle: 1st Cadet Battalion the Queen's (Royal West Surrey Regiment): Surgeon-Lieutenant A. O. Elliman to be Surgeon-Captain (dated June 11th, 1904). 3rd (The Blythswood) Volunteer Battalion the Highland Light Infantry: Supernumerary Surgeon-Major A D. Moffatt to command the Highland Light Infantry Bearer Company, Royal Army Medical Corps (Volunteers), vice Surgeon-Major Q. Chalmers, 5th Volunteer Battalion the Highland Light Infantry, who has vacated the appointment (dated June 11th, 1904). 5th (Glasgow Highland) Volunteer Battalion the Highland Light Infantry: Supernumerary Surgeon-Major Q. Chalmers is appointed Brigade-Surgeon-Lieutenant-Colonel whilst holding the appointment of Senior Medical Officer to the Highland Light Infantry Volunteer Infantry Brigade, and to remain Supernumerary (dated June 11th, 1904). 1st (Ross Highland) Volunteer Battalion Seaforth Highlanders (Ross-shire Buffs, the Duke of Albany's): Surgeon-Major J. Adam to be Surgeon-Lieutenant-Colonel (dated June 11th, 1904). 7th Volunteer Battalion the Gordon Highlanders: Surgeon-Lieutenant J. F. Robertson to be Surgeon-Captain (dated June 11th, 1904).

Consequent upon the division of the 1st Cheshire and Carnarvonshire Royal Garrison Artillery (Volunteers) into two Corps, designated respectively the 1st Cheshire Royal Garrison Artillery (Volunteers) and the 1st Carnarvonshire Royal Garrison Artillery (Volunteers), His Majesty has been graciously pleased to approve of the following, with effect from June 4th, 1904:—1st Cheshire Royal Garrison Artillery (Volunteers): Honorary Assistant Surgeon, R. E. Owen; Surgeon-Major, A. M. Archer; Surgeon-Captains, R. B. Wright and T. G. Lusk. 1st Carnarvonshire Royal Garrison Artillery (Volunteers): Surgeon-Lieutenant-Colonel, E. J. Lloyd; Surgeon-Lieutenant, O. W. Owen.

Royal Army Medical Corps (Volunteers).

Wilts and Dorset Bearer Company: Surgeon-Major H. J. Mackay, from 2nd Volunteer Battalion the Duke of Edinburgh's (Wiltshire Regiment), to be Major and to command (dated June 11th, 1904); Surgeon-Captain R. G. Worger, from 1st Volunteer Battalion the Prince Albert's (Somersetshire Light Infantry), to be Captain (dated June 11th, 1904).

Deaths in the Services.

Inspector-General Maxwell Rodgers, R.N., at his residence in Southsea on June 8th, in his seventy-second year. The deceased, who graduated M D. of the University of Glasgow and took the qualification of M.R.C.S. Eng. in 1857, entered the Royal navy in the same year, and retired in 1893 with the rank of inspector-general of hospitals. As assistant surgeon he served in the *Belleisle* and attended on the wounded during the operations at the Peiko Forts in 1858 (China medal). He served as surgeon of the *Assurance* during an outbreak of fever and cholera which broke out on that ship when in the river Danube and Black Sea in 1865. He was fleet surgeon of the *Monarch* at the bombardment of Alexandria on July 11th, 1882, and was present at the occupation of Port Said (Egyptian medal, Alexandria clasp, and the Khedive's bronze star). He was granted the Greenwich Hospital pension in November, 1896.

Brigade-Surgeon William ffolliott, R A.M.C. (retired), on June 8th, from heart failure, following an attack of influenza, at the age of 65 years. He received his medical education in Ireland, entered the army in 1862, and retired in 1890. He served in the Afghan war of 1878–80 (medal).

The Post of Director-General of the Royal Navy Medical Service.

In THE LANCET of June 11th we announced that Inspector-General of Hospitals and Fleets H. M. Ellis had been selected to succeed Sir Henry Norbury. Inspector-General Ellis entered the service in 1875 and served in the Egyptian war of 1882 and was present at Kassassin and Tel-el-Kebir, mentioned in despatches and promoted to staff-surgeon. In 1891 he became fleet surgeon, in which rank he served in the ill-fated battleship *Victoria*, flagship of Vice-Admiral Sir George Tryon, which in 1893 was sunk off the Syrian coast. In August, 1899, he was promoted to deputy inspector-general and in February last to inspector general, the following month being appointed to Haslar Hospital. We heartily congratulate this officer on his appointment to the post of Director-General of the Medical Department of the Royal Navy and wish him all success in the discharge of his new and responsible duties.

Sir Henry Norbury, K.C.B.

Inspector-General Sir Henry F. Norbury, Director-General of the Medical Department, will shortly relinquish his appointment which he has held a little over six years. Sir Henry Norbury has served 44 years and has seen considerable active service in South Africa—in the Kaffir war, 1877–78, and in the Zulu war, 1879, on both occasions being mentioned in despatches. On the occasion of the Diamond Jubilee of the late Queen Victoria he was made K C B. Sir Henry Norbury is honorary surgeon to the King, a Knight of Grace of the Order of St. John of Jerusalem, a honorary Fellow of the Royal College of Surgeons of England, and the holder of Sir Gilbert Blane's gold medal.

Superseded Officers A.M.S.

Under the above heading the *Army and Navy Gazette* of June 11th publishes a communication from a correspondent making inquiry into a matter which is stated to have been discussed freely and unfavourably in the medical service. It is as to whether the army medical officers on the Advisory Board at headquarters who happen to be junior in rank to the medical officers whose promotion comes up for consideration are allowed to sit and to vote at the Advisory Board meetings on the promotion of their seniors. If so, the correspondent points out that it is against the interests of discipline, seeing that the junior officers have benefited very materially by the supersession of their seniors, notably so in the lieutenant-colonel's rank. To this inquiry our service contemporary replies in an editorial note which calls for attention on account of its important bearing. We venture, therefore, to quote it at length.

> "Our correspondent asks us to reply to his query in some autho [illegible] may commit [illegible] be no ruling [illegible] e members of [illegible] rank to the [illegible] notion by that [illegible] whether they [illegible] aw more. The point raise [illegible] comments [illegible] Advisory B [illegible] we find exa [illegible] and then s [illegible] case an offi [illegible] places but [illegible] not only p [illegible] which he was advanced. This officer's case is no secret, and if instances can be multiplied, as we are informed they can, then something defective would appear in the Advisory Board's deliberations. We would invite discussion."

THE EMPLOYMENT OF DISCHARGED SOLDIERS

Under the presidency of the Lord Mayor of London the annual meeting of the National Association for the Employment of Discharged Soldiers was held at the Mansion House on June 13th. The Princess Louise (Duchess of Argyll) sent a letter expressing her sympathy with the work of the association and regretting her inability to attend the meeting. The report of the association stated that during the past 12 months 17,350 men had been registered and permanent employment found for 11,068. Many vacancies occurred in Government offices which warrant officers, non-commissioned officers, and men of good character were well-fitted to fill. The association continued to receive liberal financial assistance from the Government, which had made a further grant of £1500 during the past year, and the King, a life member, had again subscribed to the funds.

THE WAR IN THE FAR EAST.

There seems to be some doubt about the Japanese victory on the afternoon of June 11th, in which it is alleged that a strong detachment of the Russians was driven back in disorder on Kaichau with the loss of 860 killed and wounded. There is no allusion to such an occurrence in the Russian general's official report from Wafangko of that date. It is, of course, possible that the Japanese may have had such a success, but it must be expected that mere affairs of outposts will be constantly taking place with losses on one side or the other which become exaggerated into serious engagements. It is somewhat a matter of surprise that we do not hear more of the movement of the Japanese in the vicinity of Mukden and of the interruption of the railway to the north of that place. It is but natural to suppose that the Russians will be most unwilling to leave the beleaguered garrison of Port Arthur to its fate, but it may be accepted as certain that a general of [illegible] experience and reputation is [illegible] ficulty and risk of making the [illegible] of writing it is rumoured that a naval battle is going on, the Vladivostok fleet having escaped from port and made a dash for Port Arthur. As was the case with ourselves in South Africa charges of inhumanity have been made during the present war but there is every reason to believe that they are groundless and that as far as possible the wounded and prisoners, irrespectively of their nationality, have received every care and attention in the camps and hospitals; that [illegible] been acknowledged on both [illegible] o the Japanese forces from [illegible] are now in the field and [illegible] R.A.M.C., is with the headquarters of the 2nd Japanese Army There is great activity [illegible] in Russia in the way of war [illegible] and elaborate instructions have [illegible] ylactic inoculation of men and [illegible] East against all sorts of diseases. The English Red Cross Society at St. Petersburg has sent a donation of £2000 to Sir Charles Hardinge, the British Ambassador, to be used at the discretion of his Excellency for the relief of the Russian sick and wounded. Sir Charles Hardinge has decided to hand the money over to the Dowager Czarina who is president of the Russian Red Cross Society.

The *Ruski Listok*, in reply to many questions as to how to address letters to friends in the Far East, says that an information bureau has been established at Karbin which is kept fully informed of all the movements of the sanitary detachments. Therefore all communications should be addressed to Karbin.

The special correspondent of the *Novoe Vremya* at Karbin telegraphs that the hospital barge for the removal of the sick and wounded thence to Chabarovsk and Blagoveschtschensk has been consecrated. It is elegantly arranged and fitted. The streets of Karbin are being paved and, generally, since the energetic measures taken by the army officers and town council, the sanitary state of the town is quite satisfactory. The most serious problem is the sanitation of the neighbouring Chinese villages.

[illegible]

Correspondence.

"Audi alteram partem."

SHOULD MEDICAL MEN BE ALLOWED TO DISPENSE THEIR PRESCRIPTIONS OR NOT?

To the Editors of THE LANCET.

SIRS,—A short time ago a number of letters on this subject appeared in THE LANCET. As the question affects the public more than the profession perhaps the following case of my own may be to the point.

Last week I wanted some nitrite of amyl and sent a note by a friend of mine to a chemist in the nearest town (I live in a village) seven miles distant where there are three chemists, requesting him to send a few vaporoles or capsules, five minims, of amyl nitrite. Now comes the amusing part of the story. Mr. A had none, but "had something that would do as well." *Perhaps Mr. B had some.* My friend went [illegible] list, b [illegible] men," [illegible] such [illegible] drug [illegible] which [illegible] readers will enlighten [illegible]

Again, some years [illegible] a patient in small dose [illegible] same town he told him that he did not keep it, that it was a very old "drug," and that there were several other preparations which acted much better. Now to me this sounds very much like substitution and that the chemist, without seeing the patient or knowing anything of his complaint, judges himself to be a far more competent person to prescribe than the medical man in attendance.

Some time ago, I think it was a Mr. Howel Idris who started the agitation against medical men dispensing for the reason that they sometimes made mistakes. Quite so; we are a [illegible] that does not prove [illegible] maintain that a man [illegible] suggests such a proceeding [illegible] I know for a fact that the majority of the middle and lower class public have more faith and place more reliance on medicine [illegible] exorbitant. I have frequently given prescriptions gratis to poor persons and on inquiry have been sorry to hear that the chemist has charged 3*s.* 6*d.* for an eight ounce mixture and a few pills, the intrinsic value of the lot, bottle included, being at the outside 1*s.* Well, after reading this perhaps there are some persons who wish to prohibit medical men dispensing. If they will come forward and pay the chemist's bill I am quite willing provided there is no substitution. I am, Sirs, yours faithfully,

Y. M. JONES-HUMPHREYS.

Cemmaes, Montgomeryshire, June 13th 1904.

THE SO-CALLED PANCREATIC REACTION IN THE URINE.

To the Editors of THE LANCET.

SIRS,—The contention of your correspondents, Dr. C. E. Ham and Dr. J. B. Cleland, that the pancreatic reaction is due to lead salts is at once disposed of by the fact that other acids and neutralising agents than hydrochloric acid and lead carbonate give precisely similar results to those I have described as being obtainable with these reagents. The operations are somewhat more tedious and require considerably more care, but using, for instance, half a cubic centimetre of sulphuric acid to the ten cubic centimetres of urine and, after boiling for five to ten minutes, neutralising with barium carbonate I obtained in over 50 consecutive cases typical crystals with pancreatic urines and no reaction with normal cases.

The pancreatic crystals are undoubted osazone crystals, as their melting points and other characters show, but I am not aware that I have ever stated that they are almost identical with phenylglucosazone—in fact, I pointed out at my lecture that they more closely resembled phenylmaltosazone in most instances. The method of removing lead from the solution by means of ammonium sulphide, with subsequent heating, adopted by Dr. Ham and Dr. Cleland introduces new factors into the operation which are calculated to interfere with the succeeding stages of the "A" reaction. It is to these that their failure to obtain crystals in the six pancreatic cases they have examined is no doubt due and not to the absence of lead, which, as I have pointed out above, does not influence the result one way or the other. The clinical diagnosis of diseases of the pancreas has not been my share of the work, but I have every confidence in the surgeons who supplied me with material for my investigations. The presence of cysts, pancreatic calculi, and gross obstructions of the common duct in a considerable proportion of the cases examined is sufficient to establish the clinical value of the test, which is at present all I seek to maintain.

Dr. F. G. Bushnell's detailed account of the case in which he had the opportunity of examining the urine during life and the organs after death, is interesting further evidence in favour of the diagnostic value of the reaction and an important contribution to our knowledge of the anatomical changes associated with the particular variety of the test he obtained. Crystals dissolving in one to two minutes by both the "A" and the "B" methods are quite what one would have expected with a pancreas showing much interlobular fibrosis (i.e., damage due to past chronic pancreatitis) and a history pointing to long-standing disease of that organ.

The stage of the inflammatory reaction appears to influence the result of the test and it is possible to gauge roughly the progress of the changes in the pancreas by the difference in the amount of the deposit yielded by the "A" and the "B" methods. The short yellow crystals occasionally met with in the control phenylhydrazin test are, in some cases at least, due to traces of a form of maltose but that this is always so I am not prepared to say.

I am, Sirs, yours faithfully,

Beaumont-street, W., June 13th, 1904. P. J. CAMMIDGE.

THE POWERS OF THE GENERAL MEDICAL COUNCIL.

To the Editors of THE LANCET.

SIRS,—Many of your readers may not have realised the importance of the recent decision of the General Medical Council to apply to Parliament for power to compel the names of all students of medicine to be entered on a register under its control. Such a power would be very far-reaching, since it must carry with it the right to refuse registration to the student of any university or licensing body which would not be prepared to modify its requirements in the precise way which the Council might choose to demand. The great services rendered by the Council are recognised by all members of the profession, but there can be little doubt that its present legal powers, taken together with the moral weight which it derives from the individual eminence of its members, are amply sufficient to effect the ends it has in view.

Already the Council claims to be possessed of such rights as the following: 1. The right to inspect any examination which forms a necessary part of the medical curriculum, including even the earlier examinations in literary and scientific subjects, and to *require* such changes in scope and method as they think fit, including even the adoption of a particular system of marking. 2. The power to require examining bodies to demand from a candidate before admitting him to examination evidence that he has gone through a particular course of study, lasting for a particular period of time, conducted in particular institutions approved by the Council, and taken at a particular stage in his career.

Attempts have been made by the Council to exercise each of the above-mentioned powers and it is apparently only the fact that its claim to possess them depends upon a doubtful interpretation of the Medical Acts of 1858 and 1886 which has hitherto prevented their enforcement. There is a widespread conviction among many of those concerned with medical education that, if these autocratic requirements indicate the spirit in which the Council conceives it to be its duty to act, any further increase of its power would be eminently undesirable.

I am, Sirs, yours faithfully,

W. RAMSDEN, M.D. Oxon.

Pembroke College, Oxford, June 13th, 1904.

THORNE DEFENCE FUND.

To the Editors of THE LANCET.

SIRS,—Every medical man engaged in surgical work must feel sympathy with Dr. Mary Thorne in the recent action which she has been called upon to defend and which resulted in an unfavourable verdict against her. Although the expenses of Dr. Thorne's defence were defrayed by the Medical Defence Union, of which she is a member, she is herself responsible for the damages awarded against her and also for the plaintiff's costs which together amount to about £250. It has therefore been decided to raise a fund to assist Dr. Thorne in meeting this expense and as a means of showing the practical sympathy of the medical profession with her. We are, Sirs, yours faithfully,

WALTER S. A. GRIFFITH.
WALTER TATE.
DOUGLAS DREW.

PS.—Dr. Tate, of 32, Queen Anne-street, London, W., will be pleased to receive and to acknowledge any subscriptions to the fund. The following is the first list of subscribers:—

	£	s.	d.		£	s.	d.
Dr. C. J. Cullingworth	5	5	0	Sir William Broadbent, Bart.	2	2	0
Dr. Walter S. A. Griffith	5	5	0	Sir Victor Horsley...	2	2	0

ABSCESS OF THE FRONTAL SINUS.

To the Editors of THE LANCET.

SIRS,—I am surprised to see that Dr. R. S. Wainewright in his letter to THE LANCET of June 11th, p. 1687, referring to the external swelling caused by perforation of a frontal sinus empyema, says that he cannot find it mentioned in any book. The reason why this swelling is not accorded a prominent place as a symptom by nasal specialists is that they generally diagnose empyema of the frontal sinus at a stage considerably earlier than that of external swelling and cases accompanied by swelling usually come into the hands of the ophthalmic or the general surgeon. In spite of this, among the books I happen to have within reach this condition is referred to in "Diseases of the Upper Respiratory Tract," by Watson Williams, fourth edition, pp. 379 and 380; "Manual of Surgical Treatment," by Cheyne and Burghard (Lambert Lack's article), part v., p. 339; Heath's "Dictionary of Practical Surgery," and Sheild's article in Treves's "System of Surgery," vol. ii., p. 348. A very complete account of its causation, position, and appearance, with an illustration, may be found in Hajek's work on the "Inflammatory Diseases of the Accessory Sinuses of the Nose," pp. 135 and 145. After reading these descriptions I trust that Dr. Wainewright will no longer assert that "even the greatest nasal specialists seem still to be entirely ignorant as to its nature." I may point out that a clear distinction should be made between the swelling due to expansion of the bone by the rare mucocele and that caused by an abscess after perforation of an empyema which hardly ever expands the bone.

Dr. Wainewright further says of these cases that "all that is necessary to do is to make an incision through the swelling and pass a drainage-tube into the cavity of the nose." Now this is by no means so simple as it sounds; the opening into the nose is normally much too small to admit a drainage-tube and is always much narrowed in those cases which go on to perforation; further, the perforation is usually too small to work through and must be enlarged. These cases are severe and there are often present areas of caries and polypoid degeneration as well as associated disease of the ethmoidal cells, all of which must be treated if a cure is hoped for. It is a pity that such simple methods as Dr. Wainewright mentions are not usually sufficient but experience shows that they seldom are. The question of complete obliteration of the cavity is too long to discuss here, but there is much to be said in favour of this procedure in certain advanced cases. At least, we cannot dismiss it as shortly as Dr. Wainewright does from among our means of treating a class of case often exceedingly difficult to bring to a complete and final cure.

I am, Sirs, yours faithfully,

Wimpole street, June 14th, 1904. HAROLD BARWELL.

COUNTING MATTRESS SPONGES IN ABDOMINAL OPERATIONS.

To the Editors of THE LANCET.

SIRS,—A simple method of preventing mattress sponges being left behind in abdominal operations is to have a piece of tape sewn to one corner of the sponge. The tape should be about a foot long so that when the sponge is introduced into the abdomen the tape hangs outside over the edge of the wound on the abdominal wall. To keep it taut a leaden bead or button may be strung on to the end of the tape and secured by a knot. The beads or buttons—the button being flat is the better of the two—can be readily sterilised and, of course, used again and again. As there is a tape outside for every sponge inside all that it is necessary to do before the wound is stitched up is to count the tapes, to find if they tally, and then to draw out the sponges by pulling each tape separately. The method, I think, is used in Dublin.

I am, Sirs, yours faithfully,

June 11th, 1904. J. JOHNSTON ABRAHAM

SPLENIC ANÆMIA.

To the Editors of THE LANCET.

SIRS,—The following case of mine suggests whether it is not the removal of the spleen (as stated by Dr. F. Taylor in the Lumleian lectures) which relieves in splenic anæmia but the excessive loss of blood which takes place in such an operation, and whether bleeding *to an extreme degree* is not indicated as a method of treatment in splenic anæmia both to give an impetus to the blood-forming organs and to get rid of a poison inhibiting the action of those organs. A tin miner aged about 30 years, consulted me for extreme anæmia with enlarged spleen. No blood count was made. He failed to improve under iron and increasing doses of arsenic until he had a violent attack of epistaxis which nearly cost him his life, after which with the same treatment he completely recovered to all appearances, regained his colour, and went to America to mine where he was well and working three years afterwards. I cannot remember the after state of the spleen definitely.

I am, Sirs, yours faithfully,

Camborne, Cornwall, June 11th, 1904. JOHN H. TONKING.

RESPECT FOR DRUGS.

To the Editors of THE LANCET.

SIRS,—My attention has been called to the review of my work on "*Drugs*" which appeared in THE LANCET of May 14th, p. 1358. Whilst thanking you for the space you have given to a notice of my book and your reviewer for pointing out several slips which have evaded the vigilance of the proof-readers I cannot but think that your contributor is hypercritical in some of his comments. He objects to the statement that "all drugs are poisons," not that he disputes its truth but because he fears it may be used to throw doubt on the value of medical science. Is it not equally probable that it may help to hinder the habit of self-drugging which is so fatally fashionable? Personally I have always found it essential to impress students with a proper respect for the drugs they handle. Your reviewer does not like the system of classification I have adopted. It has its drawbacks undoubtedly, in common with every other known system, but as students have to recognise specimens it would seem well that they should consider those that are alike in external characters together—e.g., leaves with leaves and roots with roots.

May I hope that the comparative triviality of the errors and misprints which your contributor has noted indicates the absence of serious faults?

I am, Sirs, yours faithfully,

June 10th, 1904. H. WIPPELL GADD.

TAPEWORM IN A CHILD.

To the Editors of THE LANCET.

SIRS,—*Apropos* of Dr. J. A. Rigby's case of tapeworm in a child, aged 34 months, published in THE LANCET of May 14th, p. 1348, I beg to enclose a reprint of a report of a somewhat similar case in a child, aged 24 months, observed by me some three years ago.

The case was reported to the Philadelphia Pediatric Society not only as an instance of infection at a very tender age but principally to point out the danger of giving raw beef to young children—a custom quite prevalent at present in the United States and for which L. Emmet Holt is largely responsible. A tapeworm is not a desirable guest for a young child to entertain; indeed, its presence is not altogether devoid of danger, while its removal is often a matter of extreme difficulty. For this reason it would seem to be the part of wisdom to reserve the use of raw beef for those extreme cases of dyspepsia in which the proteids of cow's milk, however altered or modified, are digested with great difficulty and for the treatment of certain cases of chronic diarrhœa.

I am, Sirs, yours faithfully,

Philadelphia, U.S.A., June 1st, 1904. D. J. M. MILLER.

THE IMPURE AIR OF CHURCHES.

To the Editors of THE LANCET.

SIRS,—During the last two years I have visited during service more than 100 churches in the South of England, both in towns and country. In these days when "open-air treatment" and the merits of the open window are preached it is remarkable how the churches fail to keep pace with the times and keep their windows rigorously shut. Many country churches have no windows that will open or other means of ventilation; in others the very small and few windows made to open are kept closed. The churches in so-called health resorts are the worst offenders. They have large congregations, many services, and little ventilation. In winter artificial heating by hot-water pipes is common, and in the evening the lighting is by gas or oil lamps, and occasionally by electric light. The air at the end of a crowded service is foul beyond description. Not 5 per cent. of the churches which I have seen have any proper ventilation except the newer ones which have apertures or windows high up near the roof and other windows not hermetically closed. In the vast majority week after week the foul and stagnant air is never renewed; the dust and numerous germs, pathological and otherwise, remain year after year in the crevices of antique wood or stone work. One sees occasionally sufferers with the streaming eyes and nose of cold or influenza; one hears the cough of phthisis or pertussis. The writer has known several cases of illness directly due to visits to these malodorous and unwholesome services and many of my medical brethren could confirm this. Of course the subject is a delicate one. Some of my clerical friends readily admit the bad air of the churches but hesitate to oppose the ignorant prejudices of many worshippers and their pious horror of so-called draughts. Those I visited belonged to the Church of England. Those of other sects, so far as I can learn, are not better ventilated. In this respect, notwithstanding our boasted progress in sanitary science, the churches retain the customs of the Middle Ages. Perhaps, Sirs, you may deem the matter of sufficient importance to give this letter a place in your columns.

I am, Sirs, yours faithfully,
T. CARSON FISHER, M.D. Dub.

Paignton, Devon, June 13th, 1904.

THE FOLKESTONE PUBLIC HEALTH CONGRESS AND THE SANDGATE SCANDAL.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

(Continued from p. 1690.)

SANATORIUMS FOR PULMONARY TUBERCULOSIS: RESULTS OF THE EXAMPLE GIVEN BY THE GERMAN EMPIRE.

DEALING with the general question of sanatoriums for the treatment of pulmonary tuberculosis, it may first of all be observed that in any case there is less need for such institutions in England than in the other European countries. Dr. Brouardel, one of the reporters on the question, reminded the International Congress of Hygiene that in 1899 the deaths from pulmonary phthisis per 10,000 inhabitants amounted to 40 in Russia, 36 in Austria, 30 in France, 22 in Germany, 20 in Switzerland, Ireland, and Denmark, 18 in Holland and Italy, 17 in Belgium, Norway, and Sweden, and only 13 in England. On all sides great homage was rendered to what had been done in England, for it is well known that formerly the death-rate from this cause was as high in England as it was on the continent. It is therefore, and at the onset, somewhat of a stumbling-block in the study of the question of sanatoriums to find that the best results have been obtained in the country where such institutions can hardly be said to exist. On the other hand, and speaking in a general and broad sense, it can also be said that the second best results have been obtained precisely in that country where the movement in favour of sanatoriums has received its greatest development; indeed, it is from Germany that the impulse in favour of sanatoriums has come. Such places as Davos in Switzerland and Hyères or Mentone in the south of France suggested that there was perhaps a means of cure or of improvement available for a few well-to-do or wealthy persons; but it is to Germany mainly that we owe the conception and the practical demonstration that these advantages can be placed at the disposal of the toiling masses. This, of course, arises from that giant measure of constructive social reform—universal and compulsory insurance for all whose income does not exceed £100 a year. It is well known that this law imposes a threefold obligation. Every individual must insure against sickness, against accident, and against incapacity to work or old age. The premium paid is calculated at 1½ per cent. of the annual wage or salary earned. The employer pays one-third of this sum and deducts the other two-thirds from the wages and he is responsible for the transmission of the total amount to the right bank or fund. At present, however, the purport in view relates only to the connexion existing between the system of compulsory insurance and the sanatoriums, therefore it is not necessary to describe the law in detail. Indeed, these details are of such vast importance in their bearing on public health as well as on economical conditions that they should be familiar to all students of these questions. It is not, therefore, necessary to deal with the modification of the law on accidents raising the maximum income of the insured from £100 to £150 only in so far that it all means in practice the prevention of extreme poverty. Neither the victim of the accident nor his family can be reduced to destitution. Provision has been made for them that will in any case prevent absolute want.

The question to be considered in this respect is whether this practical "extinction of pauperism" has not done far more for the reduction of pulmonary tuberculosis than the creation of sanatoriums. Dr. Santoliquido, who is the Director-General of the sanitary services of the kingdom of Italy, was charged by his government to study and to report on this subject, and he concludes that it is the compulsory insurance and not the provision of sanatoriums that has done most in the reduction of tuberculosis.

The portion of the law that relates to insurance against old age and the incapacity to work has the more direct bearing on the questions of sanatoriums. According to Article 18 of the law of July 13th, 1889, the relief given may consist of medical treatment, medicaments, food, and gratuitous nursing in hospitals, sanatoriums, and similar institutions. Here, then, we have not only the legal sanction for sanatoriums but a fund to provide the means. Then, again, we have here the power of applying a principle that can hardly be said to exist elsewhere. The law sanctions the application of preventive treatment. All being insured and called upon to pay for each person who is invalided it is to everyone's advantage to prevent illness. The whole community then becomes as members of one single family and everyone is personally interested in preventing others from falling ill. It is in this spirit that the German sanatoriums for the treatment of pulmonary tuberculosis must be considered. It is quite as important to prevent a case of tuberculosis as to cure a case that already exists. The object in view is to reduce the number of persons entitled to sick relief. No sooner had insurance to provide pensions for the invalided been rendered compulsory than it was found that those who created the greatest drain on the funds were those who were suffering from tuberculosis. When the law had only been in existence six years it was ascertained that out of 60,000 invalids receiving pensions 8500 were suffering from tuberculosis. As this illness lasts a very long time it constitutes a very serious charge on insurance funds. Indeed, it became a moot point whether the funds would suffice in spite of the compulsory payments. Consequently the question was not merely how to cure tuberculosis and how to prevent the spread of the disease, there was also the desire to put the patient on his feet again and to enable him to return to work, if only for a short time. The preventive treatment of tuberculosis was therefore advocated, not only as a humane measure but as a sound financial investment.

The first State sanatoriums for tuberculosis were built in 1892. There were only seven sanatoriums constructed during the first four years, holding altogether 634 beds. After that the movement spread much more rapidly and by the end of 1902 there were 60 sanatoriums with 5012 beds. So far back as 1854 a sanatorium with 300 beds had been built by private enterprise; then nothing more was done till 1873 when another private sanatorium was opened. Altogether there were 16 private sanatoriums, with 1771 beds, in 1901. During that year 18,525 patients underwent the special treatment for tuberculosis in these establishments. It is estimated by some authorities that this year the number of patients thus treated throughout the German Empire will not fall short of 25,000. This, then, has been a gigantic experiment and the results should be sufficient to be taken as a basis for action. The fact is that while the general mortality has not of late decreased very much, that from tuberculosis, which from 1876 to 1886 was 31 per 10,000 inhabitants, fell to 21 per 10,000 in 1901. But it is important to note that whereas the reduction amounted to an annual average of 0·99 per 10,000 inhabitants from 1886 to 1893 it was only equal to an annual average of 0·55 per 10,000 from 1894 to 1900. The building of sanatoriums began in 1892–93 and there were but few built at first, so that the great reduction in the prevalence of tuberculosis preceded and did not coincide with the building of sanatoriums. Still as the reduction in the disease continued after the building of the sanatoriums, though not in so marked a degree, it would be an exaggeration on the opposite side of the argument to say that they have been of no use whatsoever. Particularly would such an argument be inappropriate if the financial aspects of the problem is taken into consideration. The object is to prevent or to defer the day when the worker shall be so ill as to have a claim upon the insurance funds. If without saving life the sanatoriums can increase the working efficacy of the population they have served a useful purpose. The sanatorium is not a hospital founded for the purpose of curing patients. Its object is to reduce the drain on the insurance funds by taking cases early in the development of the disease and when there is a good prospect of restoring them and of preventing their becoming confirmed invalids.

To attain such results economy would be a mistaken policy, so that not only must the best site and climatic conditions available be selected for the sanatorium but the patients must have ample and the best food. In these circumstances it has been found that the average cost for a patient's maintenance is 4*s*. a day. As the treatment on an average lasts 73 days the cost for maintenance per patient should amount to £14 12s. The principle is that this expense is not to be incurred unless there is a reasonable chance of enabling the patient to return to work. In a word, the sanatorium is an annex to the system of insurance. It is not a charity or a hospital or even a prophylactic institution, though incidentally it sometimes serves for all these three purposes, but that is not its mission. As for the results obtained, the German Imperial Bureau of Hygiene publishes statistics in regard to 6000 patients extending over the period of 1896 to 1901. It would appear that when they had completed the treatment given in the sanatoriums 67·3 per cent. were able to resume their former occupations, 7·1 per cent. were also able to work but at some lighter task, 14·6 per cent. could only do a little work, and 11 per cent. were incapable of any effort. As for the duration of the improvement, of those treated in 1897 there were 44 per cent. who had retained the full benefit during the following year, 30 per cent. in 1899, 30 per cent. in 1900, and 27 per cent. in 1901. Thus at the end of four years of the 67 per cent. of patients who on leaving the sanatoriums were said to be cured, only 27 per cent. were still well enough to earn their living at their own trades. This does not even mean that the 27 per cent. are cured from the medical point of view; they are only cured from the economic point of view. Indeed, the term "economic cure" has now become a part of the phraseology created by this problem. It does not mean that the patient has been cheaply cured but that he is so far cured that he can return to work and once more earn his living. Therefore, it is necessary to reduce very considerably the figure of 27 per cent. before the proportion of patients definitely and permanently cured can be ascertained. When this has been done it is questionable whether the proportion will be much higher than that which occurs in ordinary practice and in the usual course of nature.

The next question that arises is whether death, if not prevented, has at least been postponed. Professor Paul Jacob, of the University of Berlin, stated at the Brussels International Congress of Hygiene that the results obtained in Germany justified the vast expenditure which had been incurred. He claimed that nearly 30,000 patients were treated annually in the German sanatoriums and that 7000, or from 25 to 30 per cent., were completely cured. It was no small matter to restore to health and activity 7000 persons annually, the greater part of whom were workers and on whose labour whole families depended. A much larger number of patients were benefited but fell ill again after a certain lapse of time. This, however, was due not so much to the inefficiency of the treatment which they had received at the sanatoriums but rather to the want of treatment after they left the sanatoriums, to the misery, the overcrowding, and the poverty of the homes to which they returned, or else to the dust and the unwholesomeness of the factories and the trades at which they worked. By improving the conditions of life of the patients after they left the sanatoriums much more permanent benefits would accrue. As for the cost, that should be a secondary consideration. However, it was claimed that the sanatoriums of Germany annually and permanently restored to their occupations 7000 workers and prolonged at least for two years the working capacity and life of some 20,000 other persons. President Koehler of the *Kaiserliches Gesundheitsamt* of Berlin calculated that if the lives of 16,000 men can be prolonged for three years, this means an annual augmentation of the public wealth equal to £1,000,000. As against this benefit the cost of nursing some 30,000 persons for an average of three months each in a sanatorium represents but a small outlay. Then there is also the prophylactic advantage of treating 30,000 patients in special establishments where they cannot infect the general population. At the German Imperial Sanitary Office it has been calculated that if 12,000 patients are treated in sanatoriums and 9000 of them are returned to the community and their lives so prolonged that they are able to perform on an average three years' work, the net profit to the community after all expenses have been paid would amount to £375,000 per annum. At the same time many families would also be saved from much poverty and misery.

The most trustworthy statistics, however, are those that relate to some vast enterprise which employs and can watch constantly a large number of people. The Prussian State railways meet these requirements admirably. Here 240,000 workmen are employed and insured against accidents, illness, old age, or incapacity. Since the year 1898 whenever any of these workmen manifest symptoms of tuberculosis they are at once sent to a sanatorium. As soon as they are well enough they return to their work and are always carefully examined at least once a year by their medical officers. By these means full and accurate statistics have been secured of the immediate and the after results of the treatment. But such treatment is not limited to time. Quite a considerable number are obliged to remain in the sanatorium for more than a year and some stay for several years. By such means as many as 80 per cent., sometimes 90 per cent., have been able to return to their work after remaining a year or more at the sanatorium. The longer the stay the more desperate the case, and therefore the proportion of those who can return to their work decreases. Thus the proportions are after two years 64 per cent., after three years 55 per cent., after four years 50 per cent., and after five years 48 per cent. Dr. Grünberg of the Prussian State railways claims that these are durable results and much more favourable than those put to the credit of the ordinary sanatoriums. But then the whole administration of the State railways helps the patients. Thus, when a workman leaves the sanatorium he is given at first only light work till such time as his strength is thoroughly restored. During his absence in the sanatorium his cure has not been impeded by anxiety about his home. There are funds organised to provide for his family. Then the administration of the State railways has spent £550,000 to insure the perfect sanitary condition of the houses in which the railway servants live. By this combination of efforts many lives have been saved and prolonged and the money expended has been advantageously laid out.

It is such examples as these that have encouraged other bodies to spend more freely. The Imperial Office on Assurances published statistics showing that up to 1899 the number of pensions allotted to persons who were invalided amounted to 315,099. From one-eighth to one-tenth of these pensions were given to persons suffering from tuberculosis. The loss which this implies is rendered more serious because of the age of the persons invalided. Out of 10,000 cases 549 men and 426 women were from 20 to 24 years old, 509 men and 343 women were from 25 to 29 years old, and 439 men and 258 women were from 30 to 34 years old. These are just the ages when most persons are best able to earn good wages and to pay into, rather than to draw from, the insurance fund. Of the urban workmen who become invalids before they are 35 years old half are cases of tuberculosis. Considering the great loss entailed when such young persons are struck down by sickness the tendency is not to spare expense in seeking to prevent this evil. The average cost per patient has increased from £14 12s. to £17 3s. 6d. in 1901 and to £17 15s. 4d. in 1902. But it is claimed that the number of those who are still capable of working four years after they have left the sanatoriums has increased in 1901 from 27 to 31 per cent. among the men and from 25 to 28 per cent. among the women.

Such are some of the principal facts that can be deduced from the vast State enterprise by which the German Empire has endeavoured to cope with the evil. It does seem like a descent from the sublime to the ridiculous to compare such a gigantic undertaking with the pigmy efforts of an individual speculator who pretended to organise sanatoriums for the treatment of tuberculosis at Sandgate. To begin with, there are no statistics whatsoever to show what happens to the patients after they leave Sandgate and how many have survived the ordeal. Then, it has been seen, the German experience, which extends over some 30,000 patients annually, is to the effect that on an average the patient costs 4s. a day. Now that more is being spent it would probably be nearer the truth to estimate this outlay at 30s. instead of 28s. per week, or from £75 to £78 per annum per patient. If the capital expenditure is £200 per bed, then from £8 to £12 per annum must be added for interest on capital and a sinking fund to repay the loan. Also, there should be a further allowance for depreciation. Therefore the total annual expenditure cannot be very far short of £100 a year per patient and this, of course, makes no allowance for any profit whatsoever. But at Sandgate profit is the sole object, not profit for the funds of a national insurance, not profit for the national income and therefore a benefit to the whole community, but simply profit for individuals. To make a profit and yet to treat the patients as they are treated in Germany means that more than £100 should be paid annually for them. But the late J. J. Jones so organised matters as to make a profit out of a guinea a week. Yet the figures based on the vast experience acquired throughout the German Empire prove conclusively and mathematically that it is not possible to give at Sandgate for £54 12*s.* per annum a treatment which can for one moment be compared with what is done for the working classes of the German Empire. Germany is not so rich a country as England but in this respect the industrial classes are better provided for and are not left to be exploited by individual speculators. The experience of other nations in the treatment of tuberculosis in sanatoriums, though not acquired on so extensive a scale as in Germany, also bears on the subject, and it would be difficult to find anywhere such a scandal as that which has arisen at Sandgate.

(*To be continued.*)

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

Asylums for Lunatics in Bengal.—The Accident to the Amir.—The Control of Waterworks in Bengal.—The Plague Epidemic.—Vaccination in Afghanistan.

A RECENT Government resolution admits that the arrangements at the asylums are in many respects below the standard of the present day and that there is an absence of the skilled supervision which can be obtained only by the continuous presence of a highly trained specialist. To render it possible to provide such treatment at a reasonable cost concentration of patients is necessary, and this has of late years become practicable because almost all districts are now accessible by railway. The Government resolution refers to the possibility of concentrating European lunatics with the same object. The capacity of the asylums in Bengal during last year was 1188 and the daily average number of inmates was 1053·7. The average number of inmates per 1000 of the population was 0·01, as compared with 0·05 in Bombay and Burmah. The number discharged as cured was 96·44 per 1000—a proportion which evidently requires some explanation. In native lunatic asylums the question of diet is the all-absorbing one. For the five years ending 1892 the average cost per patient for diet was Rs. 33 13 0 (about £2 5*s.*) per annum, but for last year (1903) it was Rs. 47 11 6. It will be interesting to asylum managers to learn that the average total cost per patient in Bengal is Rs. 130 (about £8).

It is reported that the operation which Major R. Bird, I.M.S., performed on the Amir of Afghanistan the day after his arrival in Cabul was the opening of an abscess which had formed in the palm of his hand. Great pain had been previously suffered and there had been persistent sleeplessness. The native hakims rely upon oils and ointments where wounds are in question but unfortunately in this case the bone of one of the fingers was broken and blood poisoning was imminent. During the reign of the late Amir Dr. J. A. Gray was stationed in the country but no successor has been appointed.

Some new rules for the management of waterworks under the supervision of the Government of Bengal have been recently promulgated which will take their control to a great extent away from the municipal commissioners and place it under a waterworks committee consisting of the district magistrate, the civil surgeon, the district engineer, and the chairman of the municipality. This is as it should be and it would be a great improvement if all sanitary matters were controlled by a similar body. The municipal bodies of Indian towns may be looked upon as primary schools for adults in municipal administration and the elements of sanitation, but unfortunately the pupils are not apt and the attendance is very deficient. The chief evil consists in their having power, so that as the pockets of the commissioners are liable to be affected by any improvements progress has to be forced upon these bodies from outside. These new rules concern the collection of rates as well as the general control of the water-supply. I am glad to say that the efficiency of sand filters is to be reported upon regularly and that the rules for working them are to be observed.

The mortality from plague, while declining rapidly in most of the affected provinces, still keeps very high in the Punjab. In this administration no less than 30,723 deaths were recorded for last week, while 35,413 was the total for the whole of India. This death-roll compares very unfavourably with the corresponding week of 1903 when 15,408 deaths were reported. Other figures for last week published are: United Provinces, 1300 deaths as against 2229 in the previous week; Bombay Presidency, 1621, as against 2325; Bengal, 261, as against 572; Kashmir, 221, as against 313; and Bombay city 265, as against 373. Calcutta returned 134 deaths. Cholera has been very prevalent in the latter city for months past but the plague outbreak this season has been comparatively mild.

Vaccination in Afghanistan is another matter in which its ruler has to obtain assistance from India. During the late Amir's reign a regular supply of lymph used to be furnished but for some unknown reason it was stopped. Now, however, it appears that the sardars and their families ask for it and a quantity of vaccine is to be forwarded annually to Cabul. The medical assistance rendered to the Amir and his people should increase the good feeling towards the British Government.

May 26th.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

General Hospital: Resignation of Dr. Edwin Rickards.

IN 1870 the committee of the General Hospital decided to create the post of resident registrar and pathologist. It was a somewhat singular, not to say composite, appointment, for the holder, in addition to performing the post-mortem examinations and making reports on urines, &c., had to draw up for the annual report the tables of cases treated, a very arduous task, and also, strange as it may seem in these days, to administer all the anæsthetics. The latter duties have long passed into other hands but such were the conditions of the post when Dr. Rickards became its first occupant. From this position he passed to that of resident medical officer and in 1874 he was elected physician, his appointment being in addition to those previously in existence, thus raising the number of physicians at the time to five. This increase in the staff was agreed to on account of the great addition to the number of out-patients which took place at the time. Shortly afterwards, however, it was decided that it would be better to meet the difficulty by the appointment of assistant physicians and surgeons and the number of physicians was reduced at the first opportunity to four, as it is at the present time. When Sir Willoughby Wade retired in 1892 Dr. Rickards became senior physician. Dr. Rickards's connexion with the hospital has thus extended over 34 years and for 30 of those years he has been a member of the senior staff. So long a period of service has rarely been known in the annals of the General Hospital and under the new laws regulating retirements is most unlikely to occur again. Dr. Rickards is a graduate in arts and medicine of the University of Oxford and a Fellow both of the Royal College of Physicians of London and of the Royal College of Surgeons of England. He is a member of the Council of the University of Birmingham, in the medical school of which he has always taken a great interest. The present pathological laboratory was built at his expense and in part equipped by him. On receiving his resignation the board of management of the hospital passed the following resolution:—

> That the board of management have recei[illegible] resignation of Dr. Edwin Rickards, senior [illegible] desire to record their high appreciation of the [illegible] manner in which he has discharged his duties [illegible] for the past 30 years; also of the great skill and attention he has devoted to the patients under his care and to the interest he has taken in the welfare of the institution.

It was also resolved that a recommendation should be laid before the next meeting of governors calling upon them to appoint Dr. Rickards a consulting physician to the hospital in consideration of the eminent services which he had rendered to the institution during his long tenure of office. A committee has also been formed to raise a fund for the foundation of some memorial of Dr. Rickards's services to the hospital and also to show the appreciation by the subscribers of his many excellent qualities. Dr. Rickards carries with him the good wishes of all those who have in any way had to do with him and the earnest hope that he may be spared for many years' further connexion with the profession of which he has been for so long an honourable and an honoured member. By this resignation Dr. Robert Saundby becomes senior physician and a vacancy on the senior staff occurs which will shortly be filled up. As a general rule such vacancies have fallen to one or other of the holders of assistant posts. The present occupants of these positions are Dr. T. S. Short and Dr. James W. Russell.

University Notes.

When the University was founded it was felt that some opportunity of becoming graduates should be afforded to past students should they so desire. An ordinance was therefore passed permitting registered practitioners who had taken out the entire of their course in the Birmingham Medical School to proceed to the degrees of M.B. and Ch.B. by passing a final examination. This privilege has been taken advantage of by a number of past students who have submitted themselves to the very stringent examination which they have been required to face It was thought better to limit this privilege to a certain period and not to allow it to be prolonged indefinitely, and, in the first instance, five years was laid down as the limit. The fourth examination will be held in a few days, so that under this regulation next year would have been the last in which it would have been possible for a past student to obtain his degree in the manner indicated. The council of the University has, however, recently decided to extend this period by two further years, making seven in all, so that 1907 will be the last year in which an examination for past students will be held.—Owing to his appointment as inspector under the General Medical Council and the fact that the examination at one of the universities which he has to visit takes place at the same time as the final examination in Birmingham Mr. Thomas Bryant has been obliged to resign his position as external examiner in surgery. He has been replaced by Mr. Howard Marsh, professor of surgery in the University of Cambridge.—Mr. Priestley Smith has been elected an honorary member of the Gesellschaft der Aerzte of Vienna, an honour which will be highly appreciated by his many friends and former pupils.

Outbreak of Ophthalmia in Staveley.

A serious outbreak of ophthalmia has taken place in Staveley, a place in the county of Derby. It has been investigated by Dr H. Peck, district medical officer, and Dr. Sidney Barwise, county medical officer. Mr. S. Suell of Sheffield has also made a report upon the epidemic, in which he states that it is not an outside estimate to say that 200 children and parents have been affected by the disease during the last two months. It is a very contagious disease, but it is rare for it to affect such large numbers as in the present instance. It is attended by a thick discharge and the smallest particle reaching an eye would affect it. Fortunately many cases were recovering but in others the sight might be affected. Means for preventing the contagion spreading must be adopted in the first instance and it would not be necessary for the schools to be closed.

Scarlet Fever in Wolverhampton.

Dr. Henry Malet, medical officer of health of Wolverhampton, in his last quarterly report on the health of that town, states that though there has been some reduction in the scarlet fever returns they are still above the average. Of the 60 East-end cases 52 were removed to the borough hospital. Two of these were fatal cases and of the eight cases treated at home three had a fatal termination Of the 63 West end cases 50 were removed to the borough hospital, the rest being treated at home. Amongst this group there were no deaths. During the quarter the sources of infection were traceable in more cases than usual and some of the instances brought to light show how much carelessness is responsible for the spread of this disease. In one case the son of a family resident in Wolverhampton was taken ill in a town where there was no isolation hospital. His mother went and nursed him for a time and then returning home was replaced by one of the boy's sisters. After the mother's return two more of her children contracted the disease. A child was taken ill in a house where there was a children's party and was actually allowed to lie on a sofa during the party. The next day the illness proved to be scarlet fever and subsequently three of the visitors at the party developed that disease. Through a letter of complaint from a neighbour a child was ascertained to be going about in a state of free desquamation. Several cases, the origin of which had previously been obscure, were explained by contact with this child. One of the most instructive instances was the discovery of the fact that six different cases of the disease were traceable to a common milk-supply from a house outside the borough in which, on inquiry, it turned out that two cases of scarlet fever were being treated.

June 14th.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Manchester Cripples.

A HOME for cripples, the "Bethesda" Home at Cheetham Hill, a branch of the "Central Refuge," Strangeways, was established in 1889 and has since that time been supported by Manchester citizens. It has 35 beds and during the 15 years of its existence has received hundreds of poor deformed and often incurable children from the most wretched surroundings. A new wing, to be opened in the autumn, is now being erected, where there will be 70 beds available. The extension will cost £4000 and, of course, any help will be gratefully accepted. There are other societies for helping cripples which have worked independently of each other, but in November last the "Cripples' Aid Federation" (Manchester and Salford) was formed to which are affiliated the "Crippled Children's Help Society," the "Cripples' Guild," the "Bethesda Home for Crippled Children," and the "Santa Fina" work of the Manchester Art Museum and University Settlement. The objects of the federation are to enable societies and individuals in Manchester and Salford to confer together and to coöperate in ways which may supplement existing work, such as (1) the prevention of overlapping; (2) the provision (directly or indirectly) of further medical or surgical aid, an employment bureau, a home for adult cripples, special schools, and such other things as may seem to the council necessary; and (3) the collection of information as to the causes of physical disablement and coöperation with other bodies and individuals in efforts to remove those causes. This federation is not as yet well known in Manchester but its objects are so good that it is to be hoped it will meet with encouragement and success. Its headquarters are at 104, King-street.

Home Treatment of Scarlet Fever.

In his annual report Mr. A. W. Martin, medical officer of health of the outer district of Gorton, states that long experience proves that scarlet fever can be dealt with at home with better results to the community than when treated in isolation hospitals. During the five years ended in 1902 the cases removed to hospital from Gorton were 10 per cent. of the total number notified, while the attack-rate was 3·3 per 1000 of the population. This is less than the attack-rate in those towns which remove from 50 to 80 per cent. of their cases, as their average varies from 3·45 to 4 47, agreeing with the statements of Mr. E. D. Marriott of Nottingham and Dr. C. Killick Millard of Leicester. Mr. Martin says that since the year 1870 each decade has seen a decline in the severity and fatality of scarlet fever "till at the present time it is certainly not worth the tremendous expense of hospital isolation." Without speaking positively he thinks the change is "due to the alterations produced in school life by increased ventilation and less overcrowding, with the passing of the Board School Act. Scarlet fever, along with measles and whooping-cough, is essentially a school-age disease."

"The Rushing Motor-Cars."

Several of the districts round Manchester are beginning to chafe under the tyranny of the motor-car. The Cheadle and Gatley council last week passed a motion proposing that the county council should be asked to grant the eight mile speed limit to the district. At Wilmslow a speed of eight miles an hour has been decided on. At Hazel Grove the same subject was discussed, one member of the council saying that "added to the public danger these cars in their rapid progress caused great inconvenience during the summer to shopkeepers along the lines of route by raising great quantities of dust." The inconvenience from the clouds of dust affects others as well as the shopkeepers. In many places the gardens along the roads are scarcely bearable from the dust and evil smells coming from the cars, while in some districts strawberries in fields adjoining the roads are so spoiled by the dust as to be unmarketable. The high roads, and often enough the by-lanes, are not only made less agreeable for people who wish to walk, to ride, or to drive along, but they are more dangerous than before the advent of the motor-car, and the state of constant dread, the fear of being run over and killed, is so real that many timid people dare scarcely venture from their own doors. Of course, this state of things need not be and is due to the reckless selfishness or thoughtlessness of the vulgar whose manners and customs are imitated, unfortunately, with more or less success by some who ought to know better. If the craze for dangerously rapid driving along public roads does not die out spontaneously its end may have to be hastened by the authorities.

Measles in Didsbury.

The schools in Didsbury have been closed for some weeks in consequence of the prevalence of measles, 125 cases of which were reported during last month. There were also 14 cases of scarlet fever, two of diphtheria, and seven of whooping-cough.

Homes for Epileptics and Inebriates at Langho.

The Chorlton and Manchester joint asylum committee for the erection of a home for epileptics at Langho requires £78,500 for the purpose. Manchester's proportion is £41,210 which the guardians will borrow on obtaining the sanction of the Local Government Board. Mr. Jenner-Fust, the Poor-law inspector, stated at the meeting of the Manchester guardians on June 8th that for the present it was intended to build six homes which would each accommodate 40 epileptics. "This would work out at a high cost per bed but that was accounted for by the fact that administration buildings for all time were to be provided at the outset. Consequently, any additional provision for beds that might be made would work out at a much cheaper rate." The ratepayers will, perhaps, derive consolation from this, though some of them may wonder why they should pay for what is to last "for all time." The Lancashire county council came in for some criticism on account of its lavish expenditure at the meeting of the Lancashire Association of Urban District Councils on June 9th at St. Ann's. Mr. G. W. Spring, the chairman, drew attention to the spending of £70,000 on the inebriates' house also at Langho and said "he was given to understand it now possessed half a dozen inmates." Other instances were given of what was considered excessive expenditure.

Bequests.

By the will of the late Mr. Edward Hulton, newspaper proprietor of Manchester, he left £1000 to St Mary's Hospital and Dispensary for Diseases of Women and Children; £1000 to the Manchester Children's Hospital, Pendlebury; and also various bequests to Roman Catholic charities.

June 14th.

WALES AND WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENTS.)

British Medical Association.

THE South Wales and Monmouthshire branch of the British Medical Association is a large one, for it is made up of five divisions and has a total membership of 447 The activity of the branch, too, as becomes one which includes among its members the President of the Association, is proportionate to its size. At the annual meeting held at the Newport and Monmouthshire County Hospital on June 9th the retiring president, Dr. J. Tatham Thompson, introduced as president for the year Mr. O. E. B Marsh, the senior surgeon to the Newport Hospital. Dr. William Williams, the medical officer of health of the county of Glamorgan, was elected president for next year, and Dr. F. G. Thomas of Swansea was elected honorary secretary jointly with Dr. W. Mitchell Stevens of Cardiff. The President delivered a very able and instructive address upon the past and present position of surgical disease and its treatment. For the two seats upon the council of the Association to which the branch is entitled there was keen competition. Out of the 447 members of the branch 289 returned voting papers. Mr. J. Lynn Thomas obtained 152 votes and Mr. Pearson R. Cresswell 144. These two gentlemen were elected. The four unsuccessful candidates were Mr. F. W. Brook, Mr. T. Garrett Horder, Dr. Alfred Sheen, and Mr. J. R. Essex. The following motion, on the suggestion of the Cardiff division, was unanimously carried:—

> That this meeting heartily approves the application of the Court of the University of Wales for a supplemental charter to grant degrees in medicine. It further appreciates that the application is supported by His Royal Highness the Prince of Wales, the Chancellor of the University, and hereby records its opinion that by the granting of such a charter much benefit will accrue to the people of Wales.

There was at one time a little doubt among some members of the Association as to whether contributions could be made from the funds of a branch for purposes outside the general scope of the Association. The members of the South Wales and Monmouthshire branch appear to have no misgivings upon this score, for they have voted ten guineas to the Porthcawl Rest and have decided that the admission tickets represented by this subscription shall be distributed by the divisions.

Swansea Provident Dispensary.

It has been decided by the committee of the Swansea Provident Dispensary to close that institution on June 20th. The dispensary was established in 1876 and had more than 2000 members. The staff included six medical practitioners and a dental surgeon.

The Midwives Act.

A subcommittee of the sanitary committee of the Glamorgan county council has been appointed to superintend the carrying out of the Midwives Act in the county.

Cardiff Infirmary.

Owing to the resignation of Dr. J. Tatham Thompson, Mr. H. Collen Ensor becomes senior ophthalmic surgeon to the Cardiff Infirmary. Dr. Frank P. S. Cresswell succeeds Mr. Ensor and Mr. Robert Russell Thomas has been elected assistant ophthalmic surgeon. Mr. Thomas has been acting for several months as clinical assistant to the ophthalmic staff.

Ankylostomiasis.

At the last meeting of the sanitary committee of the Glamorgan county council Dr. T. H. Morris stated that there had been no cases of ankylostomiasis in the county. Arrangements have been made at the Cardiff and County Public Health Laboratory to assist in the diagnosis of any suspicious case which may arise.

British Lake Village at Glastonbury.

On June 1st a large number of archæologists in the county of Somerset visited the excavations at the British Lake Village at Glastonbury. Mr. St. George Gray, curator of the Somersetshire Archæological Society, stated that the excavations were nearly completed and that he and Mr. Arthur Bulleid, F.S.A., were preparing a work on the subject embodying the reports of specialists on the human and animal remains. Mr. Gray added that the lacustrine remains at Glastonbury were historically and archæologically of more value than any others hitherto found in Britain and he assigned them a maximum age of 400 B.C. Mr. Bulleid, who discovered the site, also pointed out various interesting features of the excavations.

The late Alderman Joseph May, F.R.C.S. Eng.

At the meeting of the Devonport borough council held on June 10th the best thanks of the council were unanimously awarded to Mrs. May for the presentation of several valuable oil paintings which were bequeathed by her husband, the late Mr. Alderman J. May, F.R.C.S. Eng., for the Free Public Library of Devonport. It was also stated that the deceased had left the whole of the valuable candelabra presented to him by the inhabitants of the town to his son, Colonel W. Allan May, C.B., R.A.M.C., for his lifetime, and upon his death the candelabra were to become the property of the borough.

June 14th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

University of Glasgow: Appointment of Professor of Geology.

AT a meeting of the University of Glasgow Court held on June 8th, Principal Story presiding, Mr. John Walter Gregory, D.Sc., F.R.S., professor of geology in the University of Melbourne, was appointed to the chair of geology in the University of Glasgow.

Mixed Classes in Medicine.

The question of the admission of women to all the classes held in the University of Glasgow came up for consideration before the University Court at the meeting held on June 8th. The women students of medicine attending Queen Margaret College—the part of the University buildings devoted to the education of women—have always felt the disadvantage of not being allowed to attend all the medical classes conducted in the University. They are limited in most cases to classes in Queen Margaret College conducted by lecturers appointed by the University Court. They therefore petitioned the senate to open all university classes to women. The senate remitted the matter for consideration to the medical faculty. The latter body reported that, in its opinion, the present was not a favourable time for any general pronouncement as to teaching in mixed classes. The question, however, might be taken up and decided for any single department in which it might be specially desired that a change should be made in the present arrangements. The senate approved of this report by the medical faculty and the decision was sustained by the University Court.

Bellefield Sanatorium, Lanark.

This sanatorium, erected by the Glasgow and District Branch of the National Association for the Prevention of Consumption and other Forms of Tuberculosis, was formally opened on June 7th by Lady Primrose who was accompanied by the Lord Provost (Sir John Ure Primrose). A large company travelled by special train from Glasgow to Cleghorn, from which place they drove through a beautiful country to the Bellefield estate. The mansion house of this estate has been utilised for accommodation of the medical and nursing staff and for administrative purposes generally. The principal building for the treatment of the patients consists of a composite iron and wood pavilion constructed on the "Speirs" system. This pavilion is well situated in a large open space with a good southern exposure. In the central portion of the block are situated five large double-bedded rooms, each having a large three-sided bay window provided with French casement doors which permit of the patient being wheeled out in bed on to a broad concrete platform which extends along the whole length of the front of the building Behind the bedrooms there is a long well-aired corridor. On the left of this central portion of the block there is a wing which forms a spacious ward for ten patients, while on the right there is a corresponding wing in which there is a large dining room. There are also suitably situated in connexion with the pavilion kitchen, cloak-room, lavatory, and test-room accommodation. Situated in the grounds are also five double-room wooden chalets for sleeping-out purposes. These are erected on the sectional principle which permits of their being easily removed to other parts of the ground if it be found necessary. The council of the association expects to be able to accommodate from 20 to 30 patients within the next six weeks. This will make a beginning of this part of its work—viz., the sanatorium treatment of men of the working class.

£20,000 for Glasgow Charities.

It has been publicly announced that while the provisions of the will of the late Mr. D. S. Cargill, of Park-terrace, Glasgow, were altogether of a private nature, yet the family, knowing that it was the intention of their father to leave certain legacies to the charitable institutions of Glasgow, though prevented from doing so by his sudden death, have determined to distribute in his memory £20,000. Among the institutions receiving legacies are the Royal Infirmary and the Western Infirmary, both of which will receive £2000, while the Victoria Infirmary, the Cancer Hospital, and the Maternity Hospital will each receive £1000. The rest of the money is distributed among the many benevolent institutions of the city and neighbourhood.

June 14th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The University of Dublin.

THE chair of Latin having been left vacant by the recent election of Dr. R. G. Tyrrell to a senior Fellowship Mr. J. Gilbart Smyly has been selected to fill that position. Mr. Smyly is the son of the late Sir Philip Crampton Smyly.

The Conjoint Board of Examinations.

Mr. Trevor N. Smith has been appointed secretary to the committee of management of the Conjoint examinations of the Royal College of Physicians and Royal College of Surgeons in Ireland in succession to Mr. Greenwood Pim who has retired.

The Irish Medical Association.

The annual meeting of this association was held in the Royal College of Surgeons, Dublin, on June 7th, Dr. L. Kidd being in the chair. There was a large attendance of members. From the annual report presented it appears that there are now 865 members. A special vote of thanks to Dr. Kidd (moved by Dr. H. H. MacDonnell, Dundalk, and seconded by Dr. R. J. Kinkead, Galway) was carried unanimously for the manner in which he filled the office of president during the past year and for the valuable assistance which he had given in the furtherance of Poor-law medical reforms. Mr. R. F. Tobin, the incoming President, then delivered his address on the Present Position of the Poor-law Medical Service in Ireland. Referring to the fact that the air was full of cries of "Forward"—literary education, technical instruction, industrial enterprises, agricultural development, and so on—he asked, Where did the great question that affected all the people of Ireland come in—the question of public health? That was left to the medical officer of health—a man located in a hovel and paid like a sweep. In two recent Irish books, "Ireland at the Cross-Roads" (Filson Young) and "Ireland in the New Century" (Sir Horace Plunkett) no reference was made to this question, and he trusted that in the next edition of Sir Horace Plunkett's book he would, with Surgeon-General G. J. H. Evatt's leave, incorporate his report on the Poor-law medical system in Ireland. Mr. Tobin thought that the cure for the ills of the Poor-law medical service did not lie in competitive examinations, and he feared that the tendency of the conditions under which dispensary medical officers did their work was "stagnation." He thought that they should make a demand for an immediate increase of salary in every union in Ireland, so as to get at least £150 as an average minimum salary all over Ireland. He doubted if in these democratic days it was possible to make the service a State one; it was neither practicable nor expedient, and he believed that if they pressed forward temperately and firmly all would come right in time. Votes of thanks were then passed to Surgeon-General Evatt for his report and to the Irish Schools' and Graduates' Association for its support. On the motion of Dr. E. C. Thompson, M.P., seconded by Dr. Scott, the council was instructed to take every advisable step in furtherance of the Medical Officers' Superannuation Bill introduced into the House of Commons by Mr. T. W. Russell. The meeting then resolved itself into committee to consider the scale of salaries and fees as fixed by the conference at Enniskillen and after a lengthened discussion the Enniskillen resolutions (fixing a minimum salary of £200 for dispensary appointments in the Poor-law medical service) were adopted. Motions were also passed that travelling expenses should be allowed dispensary medical officers as in other public departments and that efforts should be made to give the medical officers a definite leave of absence of one month in each year. The following motion, proposed by Dr. Kidd and seconded by Dr. Scott, was passed.

> [illegible]
>
> rendered, as well as all the circumstances of the case into consideration. (b) Every board of guardians be respectfully informed that the responsibilities arising in default of consultations in such cases rest entirely with them.

It was also decided that members whose subscription was more than two years in arrear should be struck off unless they should pay up within a month of receiving a demand from the secretary and that the council should be requested to take into consideration the question of appointing paid organisers for the purpose of inducing candidates to abstain from seeking vacant dispensaries, and that a committee (consisting of the president, the vice-presidents, and the honorary secretary) should be formed to confer with the Local Government Board and the boards of guardians, and others to bring about a settlement on the lines laid down by the Enniskillen meeting, with power to negotiate for such terms as may to it seem necessary and to report the same to the council. A vote of thanks was accorded to Mr. Tobin. The annual dinner was held in the evening in the Royal College of Surgeons, Mr. Tobin presiding. On the next day (June 8th) Mr. Tobin entertained the members and other guests to luncheon at the Haughton House, Zoological Gardens.

this case a second one occurred in Dr. Pauly's clinic. Theobromin has an action for the most part similar to that of theocin (theophyllin) but it never produces the effects above described. The investigations of Emil Fischer on the synthesis of the purin group have made known the constitution both of theobromin and theocin (theophyllin) and an explanation of their varying physiological effects has thereby been rendered possible. Both of them are isomeric with dimethylxanthin, but they differ from one another in respect of the grouping of one methyl molecule. Other interesting examples of this kind may be found in Dr. Sigmund Fränkel's treatise on the synthetic production of substances used in medicine. For instance, pyramidon is antipyrin in which one H is replaced by $N(CH_3)_2$. Antipyrin causes skin eruptions in about 10 per cent. of the cases in which it is used but this very seldom happens with pyramidon.

Adrenalin in the Treatment of Hæmorrhages.

At a recent meeting of the Vienna Gesellschaft der Aerzte Dr. Hermann Schlesinger showed two patients presenting hæmophiliac symptoms. One of them was a man who was liable to severe bleeding after a slight injury. A few days before admission into hospital he began to suffer from copious intestinal bleeding, the stools consisting almost entirely of blood. From 10 to 20 drops of a solution of adrenalin, of strength 1 per 1000, were given to him by the mouth every hour and gelatin was also given by the mouth. By these means the bleeding was stopped. Although he took about 30 grammes of the solution of adrenalin in two days no undesirable secondary effect was observed. The second patient, a woman, about 40 years of age, was admitted to the hospital with symptoms of Werlhoff's morbus maculosus which had appeared suddenly. The symptoms included free bleeding from the nose, mouth, and pharynx, vomiting of blood, passing of blood from the bowels, hæmaturia, and extensive hæmorrhage into the skin. As the bleedings recurred at short intervals the patient became extremely anæmic and her life was despaired of, when the administration of adrenalin brought about a sudden change. The bleeding from the urinary passages and the gastro-intestinal tract came to a stop and the hæmorrhage into the skin made no further progress. Adrenalin produced a similarly quick effect in the case of a great many patients suffering from bleeding from the bowels. Dr. Schlesinger also made successful trials of adrenalin in cases of ulcer of the stomach and the hæmorrhages of enteric fever. No toxic effects were produced, neither was there any considerable rise of blood pressure when five or ten drops of a solution of strength 1 per 1000 were taken every hour, a circumstance from which he infers that the activity of the heart is not likely to be increased by the internal use of adrenalin. No benefit seemed to be produced in hæmoptysis. An observation was made which might be of interest from a surgical point of view. It was intended to make an examination of the blood of a patient on the second day after the administration of adrenalin but the attempt was unsuccessful for the blood coagulated while in the act of escaping from the puncture. Adrenalin might therefore perhaps be useful in operations which are likely to be attended with much loss of blood.

June 13th.

CANADA.

(FROM OUR OWN CORRESPONDENT.)

Canadian Medical Association.

As several gentlemen of the medical profession in the United Kingdom are expected to be present at the thirty-seventh annual meeting of the Canadian Medical Association which convenes this year in Vancouver, British Columbia, from August 23rd to 26th, arrangements will be made whereby they can take advantage of the reduced rates from either Halifax or Montreal to the Pacific coast. The trip from Montreal over the Canadian Pacific Railway is made in five days and arrangements will be in effect for "stop-overs" after Winnipeg, so that advantage may be had of the privileges for seeing the great North-West country of Canada and the Rocky Mountains. Further, Chicago and St Louis may be reached by special arrangements before leaving Montreal or Halifax. Members of the medical profession in Great Britain and Ireland are extended a very cordial invitation to be present, as it is the first time that the association has been convened on the Pacific coast and the present occasion affords them an unusual opportunity of seeing the vastness of the Dominion of Canada and its great wealth of resource. Should any desire to put themselves in communication with the general secretary they should address Dr. George Elliott, 129, John-street, Toronto, Ontario, Canada.

Provincial Sanatorium for Consumptives opened in Nova Scotia.

The legislature of the province of Nova Scotia by an Act passed in March, 1900, appropriated a sum of money for the erection of a sanatorium for cases of tuberculous disease of the lungs. The institution is now completed and will be opened for the reception of patients in a month's time. The Government sanatorium is situated at Kentville in the famous Annapolis Valley about 70 miles from the city of Halifax. The building was erected, from plans designed by Dr. A. J. Richer of Montreal, at a cost of $20,000 and is capable of accommodating 20 patients with a complete staff. According to the terms of the Act two physicians are to be appointed from the city of Halifax who shall examine all patients and determine their fitness for admission. There will be no resident physician but one of the practising physicians of Kentville will make regular visits to the institution. The sanatorium will be in charge of a lady superintendent who is a graduate of one of the Boston (United States of America) hospitals and who has also had a special training in the Massachusetts State Sanatorium and in the Sharon Sanatorium in Massachusetts.

The Canadian Association for the Prevention of Consumption and other Forms of Tubercular Disease.

The fourth annual meeting of the above association was held at Ottawa on April 20th and 21st. The need of this organisation is emphasised by the fact that there are in the Dominion of Canada between 30,000 and 40,000 people suffering from tuberculosis. The annual report of the executive council showed that during the past year an active campaign had been carried on, over 100,000 leaflets on "How to Prevent Consumption" having been distributed. Many lectures had also been delivered and there was on the part of the medical health officers all over the country the heartiest coöperation. Dr. Ravenal, the eminent United States authority, who is assistant medical director of the Henry Phipps Institute at Philadelphia, was present at the meeting and delivered an able address on "Animal Tuberculosis in Relation to Human Health." In the whole Dominion of Canada there are now five institutions devoted to the treatment of consumption. Three of these are under private control and management, one is the property of the National Sanitarium Association, and the other is the institution recently opened at Kentville. The total accommodation of all these, with that in hospitals to which consumptives are admitted, probably does not exceed 200 beds.

Provincial Sanatoriums.

On May 24th there was held at Ottawa an important meeting of the executive council of the Canadian Association for the Prevention of Consumption and other Forms of Tubercular Disease, at which a committee was appointed to take steps to secure the coöperation of municipalities, provincial governments, and the Federal Government for the establishment of one large sanatorium in each of the provinces for the treatment of consumptives. Dr. P. H. Bryce, Ottawa, was named as the convener of this committee and other members of the medical profession who will serve thereon are Dr. Gordon Bell, Winnipeg; Dr. J. D. Lafferty, Calgary, North-West Territory; and Dr. C. J. Fagan, Victoria, British Columbia. The secretary of the association was also directed to visit Prince Edward Island, Nova Scotia, and New Brunswick in August and September with a view to lecture upon the causes and prevention of consumption and to lecture in Ontario during June and July. In addition a committee of all the members of the executive council of the association resident in Ottawa, with Dr. H Beaumont Small as convener, was appointed to take immediate action for the purpose of organising a local branch of the association in Ottawa with a view to immediate and energetic action in coöperation with those who have already moved in the matter of the establishment of a sanatorium for the city of Ottawa and the surrounding country.

A Medical Institute for Toronto.

Under the supervision of Dr. J. F. W. Ross of Toronto, who is president of the Ontario Medical Association as well as president of the Ontario Medical Library Association, a fine home has recently been purchased adjacent to the medical buildings of the University of Toronto which will hereafter be devoted to the purposes of the Ontario Medical Library and the various medical societies of Toronto. This is a most important step towards consolidating the medical societies of Toronto under one roof with the Ontario Medical Library and will tend to bring the profession in Toronto more in touch with the profession throughout the province.

Montreal General Hospital.

For the quarter ending March 31st the treasurer's account for the Montreal General Hospital shows the receipts to have been $34 598 and the expenditure $26,478. During the three months there were treated to a conclusion 754 patients in the wards, of which number 69 died. 19 of these deaths occurred within three days of their admission, making the mortality-rate of ordinary hospital cases 6·6 per cent. In the outdoor departments there were 9204 consultations, an increase of 244 over the corresponding quarter of 1903. During the quarter the following changes in the staff took place: Dr. John McCrae resigned as resident pathologist and Dr. D. B. Gillies was appointed his successor. The term of Dr. W. G. Turner as medical superintendent having ended Dr. Roland P. Campbell has been appointed as his successor. A site has been secured for the new contagious diseases hospital to be built in connexion with this institution. Upon this it is proposed to erect a building at a cost of $150,000. Of this amount only $35,000 have been subscribed, of which Sir William Macdonald contributed $15,000.

Reporting Births in Montreal.

The city council of Montreal has recently adopted a new by-law under which the physicians of that city are required and ordered to report all births occurring in their practices. Only a month ago the physicians of St. John, New Brunswick, successfully resisted a similar law in the courts on the ground that the duty of dealing with vital statistics was delegated to the Dominion authorities and not to the provincial authorities by the British North America Act. Just why physicians should be asked to work for the State without compensation, even in such a small matter as the reporting of a birth, does not seem quite clear and whilst these laws may be good and proper they should carry with them some considerations other than barren orders.

Making Medical Men by Act of Parliament in Quebec.

Almost every session of the Quebec legislature someone promotes a private Bill for the relief of some medical student who has failed to qualify himself as he should do before entering upon the study of medicine. During the present session of the legislature there has been presented a Bill of more than ordinary interest, because it proposed to relieve from matriculation in a *bonâ-fide* manner nearly 250 medical students. This naturally had the effect of stirring up the Quebec College of Physicians and Surgeons which entered a vigorous protest against this wholesale practice of relieving medical students from securing their proper qualifications. Those students who had pursued their medical studies in the proper way also rose in arms and to designate their unfortunate associates employed the expressive term "scab." Sir William Hingston states that the laws relating to the study of medicine in the province of Quebec are very unsatisfactory and students should receive some punishment for ignoring or neglecting the laws in force. I am not in a position to state what has been the outcome of the measure of relief; but the medical profession in Quebec hopes that if relief is granted this time it will be the last time any one approaches the legislature for a similar purpose. At all events this is the way several members of the profession who are in the legislature express themselves.

A Methodist Hospital for Toronto.

A short time ago the leading Methodist periodical circulating throughout Canada advocated editorially the building of a Methodist Hospital in Toronto, and in view of the congested state of all of the Toronto hospitals during the past winter there would appear to be a pressing need for some such institution. By the will of the late Hart A. Massey a legacy was left for this purpose and is available, providing that a sum equivalent to that left by Mr. Massey—namely, $100 000—can be raised

stood that the Medical F

London Hospitals; Henry Mogridge Woodward, B.A. Oxon.,

Thursday, June 9th.

Registrars and Newspapers.

Sir Walter Foster asked the President of the Local Government Board whether he was aware that the registrars of births and deaths had been accustomed to supply the weekly newspapers in country districts and small towns with the lists of deaths registered by them; whether this custom had been recently discontinued, and, if so, by whose orders; and whether he would communicate with the Registrar-General on the subject with a view to the continuance of a custom which gives information to the public.—Mr. Long replied: I am aware that in a certain number of cases lists of deaths have been supplied to the press by registrars of births and deaths. This, however, has been done in contravention of the regulation on the subject. The Registrar-General has received complaints as to the publication of particulars which may lead to the identification of individuals and he considers that any such publication tends to make persons unwilling to furnish information for registration purposes and consequently to impair the trustworthiness of vital statistics. He has recently issued a circular with a view to a strict observance of the regulation in future and I am not prepared to interfere with his discretion in the matter.

An Alleged Scandal at Drogheda.

Mr. Moore asked the Chief Secretary to the Lord Lieutenant of Ireland whether the attention of the Local Government Board had been called to the fact that a dead body was recently discovered in the morgue at Drogheda which had been left there for two months and upwards; and, if so, whether he would say who was the authority responsible for this neglect and what steps would be taken to call the attention of such authority to its duty to prevent a recurrence of such a scandal.—Mr. Wyndham replied: The Local Government Board will communicate with the local sanitary authority in respect to this matter.

Durness and its Medical Officer.

Mr. Weir asked the Secretary for Scotland whether, seeing that the position of parochial medical officer for the parish of Durness, Sutherland, fell vacant in 1898, he would state why Durness was omitted from the Parochial Medical Officers (Scotland) Return, 1903.—Mr. Graham Murray replied: I am informed by the Local Government Board for Scotland that the return furnished to it by the inspector of poor in August, 1903, stated that the resident medical officership in the parish had never been vacant since July 20th, 1896. On now communicating with the inspector of poor the Board learns that the office was vacant in 1898, although the parish was never without a medical man, as the present medical officer was in the parish for weeks before his predecessor left.

Vaccination Prosecutions.

Mr. Corrie Grant asked the President of the Local Government Board whether he was aware that at Lambeth police-court on May 31st three persons were summoned by the Lambeth vaccination officer before Mr. Hopkins for neglecting to have their children vaccinated; that in each case a solicitor appeared in support of the summons and each person was ordered to pay 25s. costs; and whether he would instruct the vaccination officer not to employ a solicitor except in cases of special difficulty.—Mr. Long replied: I have no information as to the cases referred to but I am making inquiry on the subject.

Monday, June 13th.

Epidemic of Sore-throat at Glasgow.

Mr. Weir asked the President of the Local Government Board whether he was aware that the epidemic of sore-throat which recently broke out at the Belvidere Hospital, Glasgow, was, like that at Woking last autumn and at Finchley early this year, attributable to the milk taken from cows out of health; and whether, seeing that Dr. A. K. Chalmers, the medical officer of health of Glasgow, stated that the outbreak in that city was due to teat eruption in the stock at the farm from which the milk-supply was obtained, he would consider the expediency of introducing at an early date such legislation as might be necessary to insure the occasional examination by a veterinary surgeon of all cows kept for the purposes of a public dairy.—Mr. Grant Lawson replied: I have no jurisdiction in Scotland with regard to sanitary matters, but I have seen a report of Dr. Chalmers as to the epidemic of sore-throat at the Belvidere Hospital, Glasgow. With regard to the suggestion for legislation I would repeat the answer which I gave to the honourable Member's question on March 29th last that I have caused the suggestion to be noted but that I could not promise to introduce legislation on the subject during the present session.

Ringworm and Ophthalmia.

Sir Walter Foster asked the President of the Local Government Board whether he would state the number of Poor-law children of the metropolis who were at present suffering from ringworm and ophthalmia respectively, differentiating between those housed in the Metropolitan Asylums Board special homes, those in workhouses and workhouse infirmaries, and those in the district and separate Poor-law schools.—Mr. Long said: I am informed that the number of metropolitan Poor-law children at present suffering from ringworm and ophthalmia respectively in the special homes and institutions under the control of the Metropolitan Asylums Board is as follows: ringworm, 566; ophthalmia, 345. The following is the number of these children in workhouses and workhouse infirmaries, and in district and separate Poor-law schools on April 2nd last, which is the latest date for which I can give the figures desired: workhouses and workhouse infirmaries, ringworm 184, ophthalmia 236; district and separate schools, including cottage homes and scattered homes, ringworm 159, ophthalmia 156.

Nursing of Sick Poor.

Sir Harry Samuel asked the President of the Local Government Board whether boards of guardians of England and Wales would be given an opportunity of expressing their opinion upon the contemplated Order to be issued by the Local Government Board consequent upon the recommendations of the departmental committee upon the nursing of the sick poor in workhouses and whether a draft of such Order could be furnished to the Poor-law Unions' Association of England and Wales before the same is made absolute.—Mr. Long said: I have received a large number of representations from boards of guardians on the report of the departmental committee on nursing which has led to the proposed Order and these representations have [illegible] ot undertake to afford to boards of [illegible] opportunity of making representations [illegible] der the suggestion in the latter part of [illegible]

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to The Lancet *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

Alford, Henry James, M.D. Lond., M.R.C.S., L.S.A., has been re-appointed Medical Officer of Health for the Taunton Rural District.

Barrow, G. A., M.R.C.S., L.R.C.P. Lond., has been appointed Honorary Anæsthetist to the Manchester Northern Hospital for Women and Children.

Barwell, Harold, M.B. Lond., F.R.C.S. Eng., has been appointed Surgeon Laryngologist to the Mount Vernon Hospital for Consumption.

Blamey, James, M.R.C.S., L.S.A., has been re-appointed Medical Officer for the Perranar-Worthal District by the Falmouth Board of Guardians.

Cooper, Austin, M.D., B.Ch. Dub., has been appointed Honorary Assistant Anæsthetist to the St. John's Hospital for Diseases of the Skin, Leicester-square, W.C.

Copeland, Paula T., M.B., Ch.B. Edin., has been appointed Medical Officer for Rousay and Eucilshay, Orkney.

Eccles, W. McAdam, M.S. Lond., F.R.C.S. Eng., has been appointed Examiner in Anatomy for the Fellowship Examination of the Royal College of Surgeons of England.

Fletcher, R. B., M.B., Ch.B. Vict., has been re-appointed Senior Resident Medical Officer at the St. Mary's Hospital for Women and Children, Manchester.

Fraser, K., M.B., B.S. Aberd., has been appointed Certifying Surgeon under the Factory Act for the Orrell District of the county of Lancaster.

Gunn, Elizabeth C., M.B., Ch.B. Edin., has been appointed Outdoor Physician to the Leith Hospital.

Henderson, Eleanor R., M.B., Ch.B. Edin., has been appointed Resident Medical Officer at the Royal Hospital for Sick Children, Edinburgh.

Hunt, Albert W. Dunning, L.R.C.P. Lond., M.R.C.S., has been appointed Public Vaccinator for the Chagford District by the Okehampton (Devon) Board of Guardians.

Mason, S. Herbert, M.R.C.S., L.R.C.P. Lond., has been appointed Honorary Anæsthetist to the Manchester Northern Hospital.

Miller, John, L.R.C.P. Lond., M.R.C.S., has been appointed to the Medical Charge of Troops at Topsham Barracks, Exeter.

Robertson, Eva A., M.B., Ch.B. Edin., has been appointed Resident Medical Officer to Craiglockhart Poorhouse.

Scott, Sydney, B.S. Lond., F.R.C.S. Eng., has been appointed Surgeon to Out-patients at Evelina Hospital for Sick Children, London; also Chief Assistant in the Aural Department, St. Bartholomew's Hospital.

Wilkes, J. Hamilton, L.D.S., R.C.S. Eng., has been appointed as Honorary Dental Surgeon to the St. John's Hospital for Diseases of the Skin, Leicester-square, W.C.

Willcox, W. H., M.D., B.Sc. Lond., D.P.H., has been appointed Medical Registrar to St. Mary's Hospital.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

Birkenhead, Borough Hospital.—Junior Resident House Surgeon. Salary £80 and fees.

Birmingham and Midland Eye Hospital.—House Surgeon. Salary £75 per annum, with board and lodging.

Central London Sick Asylum, Colindale-avenue, Hendon, N.W.—Second Assistant Medical Officer and Dispenser. Salary £75 per annum, with board and residence.

Coventry and Warwickshire Hospital.—Assistant House Surgeon. Salary £60 per annum, with rooms, board, washing, and attendance.

Derbyshire Royal Infirmary.—Senior House Surgeon. Salary £100 per annum, with apartments, board, &c. Also Assistant House Surgeon for six months. Salary at rate of £60 per annum, with apartments, board, &c.

Dumfries and Galloway Royal Infirmary.—House Surgeon. Salary £50 per annum, with board and washing.

Evelina Hospital for Sick Children, Southwark, S.E.—Eight Clinical Assistants in the out-patient department.

Hartshill, Stoke-upon-Trent, North Staffordshire Infirmary and Eye Hospital.—Assistant House Surgeon for six months. Honorarium of £25, with board, lodging, and washing.

Hospital for Consumption and Diseases of the Chest, Brompton.—Resident House Physicians for six months. Honorarium of £25.

Hospital for Sick Children, Great Ormond-street, London, W.C.—House Physician, unmarried, for six months. Salary £20, with board and residence. Also Ophthalmic Surgeon.

Hull Royal Infirmary.—Casualty House Surgeon. Salary £50, with board and lodging.

Isle of Man General Hospital and Dispensary, Douglas.—Resident House Surgeon, unmarried. Salary £82 per annum, with board and washing.

LIVERPOOL, DAVID LEWIS NORTHERN HOSPITAL.—Junior House Surgeon for six months. Salary at rate of £70 per annum, with residence and board. Also Second Honorary Anæsthetist.

Notes, Short Comments, and Answers to Correspondents.

ANOTHER QUACK CURE FOR CANCER.

IF warnings against the deceptive promises of quack cures and treatments were any good the general public should by now prove adamant to the specious allurements of all kinds of false medical advertisements. People, however, for one reason or another, continue to be deceived into wasting their money and damaging their chances of health and nothing prevails against what appears to be an inherent frailty of human nature. Nevertheless, when we see a more than usually flagrant example of deceptive pretence we cannot help inveighing against it. Particularly we like to attempt the destruction of advertisements which claim the cure of cancer. The very name of cancer carries terror and when any person believes that the dread scourge has fallen upon one who is near or dear to him he is apt to be the readiest prey to the advertising quack. Given up perhaps for hopeless by the honest and orthodox who realise how little there really is to be done for him a patient of this kind turns a ready ear to anyone who will promise him relief. Such promises he will find awaiting him on all sides, promises to be fulfilled equally little to whatever side he

equal impartiality whetl

door of violet leaves, "

"Bramarsandt" is the latest of these patent remedies that claim to cure cancer and is not distinguished from others by its blatant and unjustifiable promises. It professes to be a permanent cure for cancer without operation and it has nothing to support it but its own professions. We mention it merely in the faint hope that a few may be spared the misery that these quack cures cause so widely to friends and relatives of the unhappy victims of cancer, doomed to disappointment by the fallacious and audacious hopes that these advertisements hold forth.

A PRIVATE CLUB.

THE medical officer of the West Brixton Medical Aid Society has submitted to us a copy of the rules of that society which have been designed to do away with the evils of canvassing. The fifth rule is: "The society shall have no canvassers and can only be increased in membership by private recommendation," and in further support of this rule the following declaration form is submitted to those who desire to become members of the society.—

> *I desire myself*, my wife, and my *family (strike out description not required)*, to become a member of the West Brixton Medical Aid Society, and I solemnly affirm—first, that none of the persons involved have ever been attended regularly by a Brixton, or other local, medical man; and second, that my family has not a total income of more than £2 5s. a week.
>
> *Signed* ....
>
> *Address* ....
>
> *Date* ....

He has invited our opinion upon the ethical position of a medical man issuing such a declaration. We think that the clause and *declaration sufficiently safeguard him from any censure by the* General Medical Council.

ASSOCIATION FOR THE ORAL INSTRUCTION OF THE DEAF AND DUMB.

THE Association for the Oral Instruction of the Deaf and Dumb, which is under Royal patronage and has the Earl of Crewe for its president, has just issued its annual report, which shows that the work of the past year has been very successful. The practising school was attended during 1903 by 52 pupils, 27 girls and 25 boys, and the highest Government grant was obtained—namely, £90 for general instruction and £60 for technical instruction. It should be

outside its immediate sphere of work who derive the advantages of the oral system from the instruction of teachers trained at the college. Although the work done by the association is satisfactory the same cannot be said of its financial position, for there is an annual excess of expenditure over income of at least £500. It is to be hoped that the charitable public will not allow this deficiency to accumulate.

CONFIDENCE IN VACCINATION.

THE universal experience of small-pox hospitals shows that officials and visitors who have been efficiently vaccinated within the seven or eight years preceding exposure to infection never contract the disease, and Mr. A. W. Martin, medical officer of health of Gorton, Manchester, recently offered to give a convincing proof of his firm belief in the immunity so easily obtainable. On the occasion of an antivaccination lecture recently delivered in Gorton Mr. Martin invited the principal speaker to bring his young son and to visit the small-pox hospital in company with Mr. Martin and his son, aged nine years, who had been vaccinated and revaccinated. The invitation was declined, a result which was, perhaps, fortunate for both sides. If either the antivaccinationist or his son had caught the disease and died from it an immense amount of frothy declamation would have been poured forth, denouncing Mr. Martin as guilty of a cruel murder.

AMBER AND CANCER.

WE have received the following letter from the Cape Colony:—

> SIRS,—It is a hard thing for us not doctors to bring forward a medical argument in which that profession has made a most exhausting study. It may seem presumptuous on our part to hold hard to our theory in the solution of a disease which has baffled the medical profession in the past and has given the present a difficulty which perhaps they are on the verge of completing. We, the runners-up in the race for one of the chief prizes in the medical world and in the cause of suffering humanity, will put forward a simple theory in the following manner. We will come straight to the point of our article and say what will cure cancer. In our opinion to grapple with a disease which thrives or decreases according to the constitution of the patient is not with the knife, while a remedy may be found to stay the course of the growth by enclosing it in a bond which is impossible to break. What is that which will hold the smallest atom of living germ and which is perfectly harmless to the patient? Our reply is amber, that extraordinary vegetable substance which was known to the Greeks as ἐλέκτρον [*sic*], and from which we derive our modern word "electricity." We conclude this somewhat ambiguous article by saying that proof will put to the test what we write and that history being stranger than fiction gradually bears out the fact that there is nothing new under the sun—no, not even the cure for cancer.
>
> I am, Sirs, yours faithfully,
>
> May 14th, 1904. R. MIDDLETON.

Perhaps our correspondent will enlighten us in the future as to how the amber is to "enclose the growth in a bond which is impossible to break."

WESTERN OBSTETRICS IN THE EAST.

DR. J. W. Ballantyne of Edinburgh contributes to the *Women Students' Medical Magazine* for June an article on Western Obstetrics in the East compiled from letters received by him from medical women resident in China and India. The Chinese, we are told, are beginning to have such faith in the power of western medical science and practice that they will send for an English practitioner from great distances; nevertheless the Chinese dread of the foreigner greatly hampers the work of the western practitioner of medicine. In a case where forceps were indicated these instruments had to be exhibited in the guest room of the mandarin, whose wife was the patient, and their use explained by means of diagrams to the patient's brother, two gentlemen visitors, and some boys. The lying-in chamber of a Maharonee is described as a "horrid little hole," 10 feet by 5 feet, built of stone, with no window and only a small door. The article, though brief, throws much light upon the difficulties attending obstetric practice in the East and makes very interesting reading.

AN EMERGENCY POCKET CASE BOOK.

UNDER this title Messrs. Reynolds and Branson, Limited, of 13, Briggate, Leeds, publish in book form a set of 30 clinical charts designed by a captain in the Royal Army Medical Corps. The charts are ruled with spaces for entering the patient's history and condition when first seen, as well as daily notes of the progress of the case, temperature, pulse, respirations, motions, medicine, and diet. In many departments of clinical work a note-book of this kind might be found useful for the making of brief memoranda to be expanded subsequently. The price of the book of charts is 6*d*. (postage 1*d*.).

"ENTERPRISE."

IN reference to the letter headed "Enterprise" (THE LANCET, May 7th, 1904), we find on inquiry that we have been entirely in error in describing the gentleman referred to as having held no appointments entitling him to style himself a specialist. We find that he has every right to style himself a specialist on the diseases of the eye, ear, and throat, and we trust that our mistake will not in any way injure the gentleman in question.

THE DANGERS OF EPILEPSY.

THE Manchester city coroner held an inquest on June 10th as to the death of a foreman printer named Thomas, 38 years of age, who was the subject of epilepsy. On his way home from work about 4.20 A.M. on May 18th he was seen to fall. Two postmen also going home from work went to his assistance and held him as well as they could until two policemen came. The latter decided to go for an ambulance and while they were away two other policemen came up and assisted the postmen to hold Thomas, as he continued to struggle. The officers took him in a tramcar to the Infirmary where some wounds on his face caused by his fall were dressed. He was then taken home and put to bed but he gradually got worse and died on June 8th. Mr. S. C. Salter, who attended him, made a post-mortem examination and said that all the wounds which he found except one might have been caused by his own violence and his fall. "But there was an abrasion of the throat which appeared as though someone had gripped him with force that was unnecessary, with the result that it was so tender that he could not swallow sufficient food. This injury could not have been caused accidentally. Death was due to heart failure following on pneumonia as an indirect result of his injuries." A brother of the deceased stated in evidence that the latter told him that when he recovered consciousness two policemen were sitting on him and treating him roughly. The constables who took Thomas to the infirmary and others who saw the affair said that nothing was done to him beyond holding him and preventing him from hurting himself. The verdict was that death was due to natural causes, and as to the injury to the throat the jury returned an open verdict and exonerated the police from all blame and thought that they had acted with the greatest kindness. This is quite in accordance with the general character of the Manchester police, but it is a pity that the injury to the throat was not accounted for.

REPUTED 130 YEARS OLD.

THE death is reported at Karkoff of a man reputed to have seen 130 years of life. He claimed to remember laying bricks with his brother at the building of the University of Karkoff over a century ago. Ivachnenko, the man referred to, was blind for ten years before his death.

◆

S.—There is very great probability that the child will show signs of the disease, even if abortion should not occur. In spite of the absence of symptoms in the wife she should receive a thorough but careful specific treatment. Our correspondent does not state the stage of pregnancy now reached, but the earlier it is the greater the chance of preventing syphilitic manifestations. It is important so to adjust the doses of mercury that the desired object may be attained without impairing the wife's health. The husband would probably also be the better for a course of treatment. We do not publish the letter, as the patients might fear identification.

P. G. T.—The questions cannot be answered off-hand. All the circumstances (and some have not been communicated to us) should be taken into consideration. Our correspondent requires the assistance of a lawyer.

Mr. John H. Russell.—The Viavi treatment has been thoroughly exposed in our columns and in those of *Truth*.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Queen-square, Bloomsbury, W.C.).—3.30 P.M. Mr. Gunn: Ocular Paralyses

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

Will Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, MR. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. *The Proprietors of* THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and *do so* collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

METEOROLOGICAL READINGS.
